 Fern collecting in Devonshire, 376
 Fern house in February, 232; in April, 448; in May, 538
 Fern Sumach, 375
 Fernery, cool, climbers for, 333; my indoor British, 566; hardy, 377
 Ferns: tree old stumps of, 58; on the eastern Scottish Border, 457; native, and fern culture in Ireland, 477; filmy, climbing, 520; *Allosorus crispus* and other British, 652; from spores, 662; for baskets, 683
 Fertility of oranges, 476
 Fertilization of cereals, 136
 Fertilizing melons and cucumbers, 591
 Ferulas, or giant fennels, 499
Ficus religiosa, 435
 Figs in midwinter, 204
 Finsbury and Southwark Parks, 46
Fistulina hepatica, 458
 Flavouring with leaves, 535
 Flavouring with seeds, 535
 Flores in town, 658
 Florida, picturesque springs of, 398
 Florists' flowers, 26, 158
 Flower basket for vestibiles, 446
 Flower beds, effective, 536
 Flower factories in Belgium, 691
 Flower garden for December, 25; for January, 151; for February, 240; for March, 320; for April, 448; for May, 532; for June, 620
 Flower garden: decoration, 562; fashions for 1872, 517; nature's, 517; tobacco in, 277; young conifers in, 121
 Flower-pot, a new and excellent, 27
 Flower shows, early Irish, 680 (*see Societies*)
 Flower vases, harmonies and contrasts in, 578; trumpet-shaped, 62
 Flower-verses, 665
 Flower gardens, modern, 71
 Flower gardening, modern, 8, 479; of the present day, 440
 Flowers, and fountains, 131; for the dinner-table, 137; under artificial light, 138; double, 152; for graves, 261; spring, a garland of, 278; wild, for gardens, 279; early, 304, 441; early spring, 320; artificial, and their makers, 326; mountain, 330; early hardy, 375; flying, 367; of fashion, 430; and perfumery, 446; for decorating vases, on choosing, 470; for vases, on choosing, 523; for certain forms of vases, 578; dinner-table centre-pieces for, 631; winter, 699
 Flying flowers, 367
- Flying flowers and running water, 462
 Fontainebleau—geometrical flower gardens, 617
 Fontenelle and his asparagus, 62
 Food for the garden, 219
 Food of plants, 134, 138; of small birds, 568
 Footpaths, English, 374
 Forcing: lilacs, 166; roses, a simple plan for, 462; Paul's scarlet thorn for, 462; may, 502
 Forest, pine, in the Jura, 332
 Forest trees, culture of, 53; replanting, 221
 Forests, of India, 179; effects of on climate, 572; of England, a sketch of the laws, courts and officials of the mediaeval, 654
 Forget-me-not, 120
 Fork, good digging, 22
 Formal margin, 121
 Foster's apricot shed, 35
 Fountains, 270; garden, movable, 82
 Foxglove, the, 150
 Fragrant flowers, 94
 Frame, warm, 255
 France, sea pine plantations in, 434
 French: paradise stock, 638; peasant fund, 225
 Frijoles, 116
Fritillaria meleagris, 541
 Frost, effect of on conifers, 169
 Fruit, best kinds of, for a small garden, 106; a neglected, 185; dried, our trade in, 189; on railway embankments, 270; bees destructive to, 358; improvement in Canada, 536; at Combe Abbey, 560
 Fruit-buds, preservation of, 106
 Fruit-crops, injury to, 476
 Fruit culture, profitable, 61; railway side, 206
 Fruit eaters, parrots as, 430
 Fruit farm, a Worcestershire, 61
 Fruit garden: for January, 149; for February, 227; for March, 321; for April, 449; for May, 538; for June, 620
 Fruit label, new, 270
 Fruit picking in market gardens, 703
 Fruit preserving jar, American, 36
 Fruit syrups, sham, 469
 Fruit thinning, 586
 Fruit trees, the Author of "Waverley" on planting, 18; for ornament, 34; for growing against an oak fence, 106; a new way to make, 123; seedling, how to induce to bear early, 124; on walls and espaliers, upright system of training, 148; re-grafting worthless, 227; a new way to make, 228; for cottagers, 229; moss on, 296; January's teaching, 321; suckers, 439; drainage for, 470; orchard house, in May, 533; on walls, 557; summer pruning of, 611; overcropping, 638; on high and low land, 704
 Fruit trellises, improved, 60
 Fruit wall, aspects suitable to the various kinds of, 20
 Fruit walls, north aspect of, 61; wiring, 149; old, wash for, 439; glass and iron coping for, 508
 Fruiteer's baskets, law in reference to, 196
 Fruits, food value of, 65; striped and variegated, 128; new, of 1871, 177
 seedling, 440; indoors in December, 35; outdoor in April, 449; outdoor in May, 533; best hardy, 660; thinning hardy, 682
 Fruits and vegetables, tinned, 79
Fuchsias in the open air, 652
 Fungi, edible, 35

INDEX.

- Boughs, overhanging, 342
 Boulevard, new American, 46
 Bouquet flowers, heartsease as, 493
 Bouquets for the hand, 493
 Bouvardia Davidsonii, 146
 Box, odour of, 143
 Brackets for plants, 581
 Bramble leaves in winter, 582
 Bridge, rustic, without nails, 52
 British Columbian conifers, 464, 502, 551
 Broad-leaved sea lavender, the, 702
 Broccoli, 246, 301; protection of, 111; hard ground for, 274
 Brooklyn, the new park at, 684
 Broome's (Samuel) memorial, 198
 Browne's grandiceps, 547
 Brussels sprouts, modes of cooking, 197
 Buckinghamshire orchids, 499
 Buckland, 28
 Buffalo berry, the, 573
 Bug, woolly or American, destruction of, 244
 Bulbs, instructions for the growth of, in windows, 83
 Bulletin of a floral celebrity, 555
 Bullfinches, 357, 444
 Bupthalmum speciosum, 652
 Burning bush, the American, 332
 Butcher's broom, with berries, 19
 Buttercups and geese, 499
- C.
- CABBAGE, miniature Savoy, 116
 Cabbages, preserving, 208
 Cacti, hardy Mexican, 262; cultivation of, 483
 Caladium esculentum, 585
 Caladiums for room decoration, 631
 California, the vintage of, 20; among the big trees in, 53; the tomato in, 208
 Californian radish, 68; quail, 153; dye weeds, 186; columbine, 608; wines, 650
 Calceolaria, 391; shrubby, 260, 456
 Camellia, outdoor cultivation of, 584
 Camellia-house, tea-scented Noisette roses for, 166
 Camellias, why they drop their buds, 635; and myrtles in Leicestershire, 543
 Canada, snow apple of, 384; fruit improvement in, 536
 Cannas, 686
 Canterbury bell, rosy, 608
 Carbolic acid plant, 146
 Carbolic acid v. moulds, 402
 Carices, large Norfolk, 391
 Carnations, tree, 64, 119, 260, 683
 Carnations and picotees from seed, 420; stake for, 518
 Carol of seed-time, 385
 Carrot pudding, 197
 Case for sending growing plants to distant countries, 64
 Castor-oil plant, 511
 Caterpillar, gooseberry, 677
 Caterpillars, hairy, 254; hemp versus, 445; and cauliflower, 254
 Cat's-foot, the mountain, 687
 Cats, how to keep out of town gardens, 114
 Caucasian plane, 572
 Cedar trees, a talo about, 195
 Cedar of Lebanon killed by frost, 618; noble, 665
 Celery, keeping, 712; prize, 300; Simpson's collars for, 434
 Cemetery, new, at Edinburgh, 217; Coventry, 594; at Philadelphia, 668
 Cemeteries, 146
 Central Park, New York, 24, 511, 630
- Cerasus serrulata, 573
 Cercals, fertilization of, 136
 Chalk, trees and plants for planting on, 373
 Chamærops excelsa, 479
 Champignon, fairy-ring, 333, 383
 Channel Islands, pearls in, 384, 415, 535
 Charcoal dust, use for, 469
 Chatsworth, rockwork at, 50
 Cheiranthus Marshallii, 653
 Chemical fumes, damaging a crop by, 196
 Cherry, double-flowering Chinese, 573; grafted on the laurel, 683
 Cherry laurel v. aucuba, 466
 Cherry plum, 107
 Cherry tree, the Dyehouse, 321
 Cherries, 13
 Chestnut, great, of Mount Etna, 186
 Chickens v. insects, 244
 Chinese primroses, 261, 325; in winter, 91
 Chinese showy-flowered crab, 465
 Chinese narcissus, 513
 Chinese double-flowering cherry, 573
 Chinese rice-paper plant, 627
 Chiswick trial of peas, 628
 Christmas : vase, 93; horticulture in Vienna at, 150; roses at, 305
 Churchyards, our country, 713
 City graveyards, desecration of, 109; parks, situations of, 177; mortality, 168; violets, 500
 Cities, trees and plants in, 2
 Clematis montana, 653
 Clematis, hardy, 375
 Clerodendrons, culture of, 615
 Cianthus Dampieri, 368, 563
 Climate, effects of forests on, 572
 Climbers for a cool fernery, 233; for rafters and walls, 233
 Climbing species of asparagus, 367; filmy ferns, 520
 Clivia nobilis, 637
 Cockchafer, 164; tenacity of life in, 358
 Cocoa-nut groves, 250
 Coffee, how to make the most of, 596
 Cold, extreme, 322
 Cole slaw, 197
 Colocasia odorata, 323
 Colorado produce, 116
 Colosseum in Regent's Park, 178
 Combe Abbey, 559; landscape and water at, 559; trees at, 559; plant-houses at, 559; palm-grass at, 660; fruit at, 560
 Common laurel a usurper, 129
 Compass plant, the, 17
 Conifers : planting, 54; young, in the flower garden, 121; effects of frosts on, 169; pruning of, 261, 393; hybrid, 357; Jeffrey's British Columbian, 464, 502; in boggy soil, 573
 Coniferous trees in Connemara, 571
 Durango root, 209
 Connemara, coniferous trees in, 571
 Conservatory, a small, how to heat, 110; in January, 145; in February, 231; in April, 418; in May, 531; Mr. Besemer's, 170; Kibble, erection of in Glasgow Botanic Garden, 434
 Conservatory, outside shading for, 502
 Conservatories in the natural style, 181, 219, 260, 311; for cool orchids, 325
 Convict gardening in India, 86
 Cookery, the "why" in vegetable, 653
 Cooking Brussels sprouts, modes of, 197
 Cooking the orange-milk mushroom, 596
 Cool orchids for Conservatories, 325
 Corn marigold, the, 502
 Cornish strawberries and bush-fruit, 20
 Cornwall, Market gardening in, 21
 Cordyline indivisa, 15
 Coronilla Emerus, 693
- Cotoneaster for walls, 412
 Cottage-gardens, Dutch, 48
 Cottager's garden, the, 333
 Country churchyards, our, 713
 Coventry cemetery, 594
 Covering, hardening asphalt, 309
 Cow Parsnip, the, 326
 Cow Tree, the, 306
 Crab, showy-flowered Chinese, 465
 Cranberries, 410
 Crataegus cordata, 501
 Creeping Myrtle, the, 324, 410
 Crinum capense, 687
 Crocuses, lost, 391
 Cropped trees and architectural lines, 210
 Crystal Palace Company, 112
 Crystal Palace, rose show at, 624
 Cucumber in the open ground, 627
 Cucumber: smooth var. of, soils for, manures for, 424; principles of cultivation, 436; air and moisture for, upon dung beds, preparing the dung for, 469; dung and leaves for, forming the bed, 575; bed improved, 576; another kind of hot bed, 590; in brick pits, French system of making hotbeds, 590; planting of, 611, 665; "Marquis of Lorne," 612; on walls, 665; cultivation of, 627; propagation of, 666; Russian way of dressing, 116; in moss, 424; Polish mode of preserving, 428; for seed, 665
 Cucumber tree, heart-leaved, 420
 Cupressus sempervirens, 100; macrocarpa, 220, 330, 333
 Currant tomato, 383
 Currant trees, scale on, 350
 Cuttings, mode of transmitting, 161; rose, 162
 Cyclamen, culture of the, 501
 Cyclamens, spotty, 462; the culture of, 699
 Cydonia japonica, 573
 Cypress: upright, 130; the Monterey, 330, 333; as a hedge plant, 372
 Cypridium Calceolus, 305; candidum, 517
 Cytisus nigricans, 504; black, 504; elongatus, 661
- D.
- DAFFODIL GARDEN, 455
 Daffodil garden, my, 419
 Daffodils, 391, 430, 458
 Dampier's glory pea, 368, 377
 Daphne indica, 90
 Darlingtonia californica, 396
 Date tree, what it is to the Saharians, 322
 Dear seed, 158
 December: indoor garden in, 31; kitchen garden in, 41; flower garden in; shrubberies in, herbaceous and alpine plants in, 25; pits and frames in, rose garden in, 26; stove plants in, 31; greenhouses in, 32; orchid house in, 32; fruit garden in, out-door fruits in, 34; in-door fruits in, 35; arboretum in, 79
 Deciduous pruning, 264
 Desert, sowing the, 598
 Deserted favourites, 239
 Destruction of trees in Kensington Gar dens, 693
 Devoniensis rose, 376; history of, 433
 Devonshire, fern collecting in, 376; absence of mistletoe in, 436
 Dianthus brachyanthus, 687
 Dicentra eximia, 608
 Dielytra spectabilis, 233
 Digging-fork, good, 22
 Dimorphanthus mandshuricus, 117

INDEX TO VOLUME I.

A.

ABELIAS, the, 46
Abies, 464; Menziesii, 155; canadensis, 195
Acacia humifusa, 73; Ricciana, 146
Acanthus, 303
Acer Negundo variegatum, 333
Achillea aurea, 586
Adamson, last years of, 186
Adansonia digitata, 240
Adiantum rubellum, 637
Adonis pyrenaica, 608
Adulteration, 344
Æthionema grandiflorum, 155
Agaricus procerus, 178; gambosus, 623
Agave "telegraphica," 51
Agaves, potting, 369, 462, 494
Ajuga alpina, 608
Albert memorial, Kensington Gardens, 341
Alligator pear, 104
Allosporus crispus and other British ferns, 562
Almond, dwarf, 503
Alocasia metallica, 146, 370
Aloe, American variegated, 679
Alpine forest land, the regeneration of, 710
Alpine garden, 497, 512, 562, 605; conditions of success in, 463
Alpine plants green in winter, 305
Alpine strawberry, 188
Alpines, 204; stove, 346
Altyn Towers, 619
Alyssum olympicum, 608

THE

AN

ILLUSTRATED WEEKLY JOURNAL

OF

GARDENING IN ALL ITS BRANCHES.

THIS IS AN ART
WHICH DOES MEND NATURE: CHANGE IT RATHER: BUT
THE ART ITSELF IS NATURE.—Shakespeare.

FOUNDED AND CONDUCTED
BY
WILLIAM ROBINSON,

AUTHOR OF "ALPINE FLOWERS FOR ENGLISH GARDENS," "THE WILD GARDEN," ETC.

VOL. I.

LONDON:
37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.
1872.

J. C. Loudon

new terror to the lower regions. If anybody doubts the true cause of the terrible climate of our large cities, let him walk forth at three or four o'clock in the morning into the heart of one of them, —say, Endell-street, St. Giles's, in November and December, when the fogs are at their worst. If he has any memories of the fog of the previous evening he will be surprised to see the street quite free of fog, the buildings not only visible, but perfectly clear in outline; and, strange fact for St. Giles's—the air pure! Let him sally forth again at from half-past seven to half-past eight, and he will find a change; the street is filling with a bluish foulness, the buildings losing shape. An hour later and the smoke, which we fancy would vanish, after passing up the chimney, has fallen down into the street, dimming the sight, and stinging us as we breathe it. In the more open spaces the effect is the same. When the chimneys have ceased to vomit for a few hours, the noble lines of the Thames Embankment stand out clear and bold; but a little before breakfast a new climate usually sets in. For a short time the sun is seen like a red lamp in the sky; but soon all is over, and very soon highly-civilized persons are steering themselves, as best they may, through a choking atmosphere, feeling about as happy as trout, in mud, and blaming our dear climate for it all!

It is not the climate, which has bred a noble race for ages, that we should blame, but our own complacent stupidity in resting content under an evil, which, as half the population of these islands is now gathered in towns, has a hurtful effect on the whole nation.

We find in the *Times* a letter from somebody who is actually bold enough to hope that the removal of this smoke curse of ours may be a "possible reform of the distant future," and who complains of having to "leave a suburban residence a few miles from the Bank in clear autumn sunshine, and to pass through gradually-deepening gloom into the lurid, orange fog of the City, there to struggle through his work by gaslight in a state of semi-asphyxia."

Poor fellow! Will none of our statesmen consider the millions who spend their nights as well as their days in such an atmosphere, and even in much worse? For it should be understood that there are many parts of London much worse than the City, where, in consequence of the comparative absence of domestic fire-places, the air is usually much clearer than in such a neighbourhood as Lission-grove.

It may be a difficult problem to solve, but surely there is no difficulty or no expense to which we could be put in the defeat of this smoke monster, for which we should not be abundantly repaid by its destruction. Lengthened days, or at least some of heaven's light in those we have, and undefined air, are surely blessings, to secure which we might well submit to any inconvenience. It seems to us that if questions were brought forward in the degree of their importance, the smoke plague of our cities would be one of the first before Parliament.

Trees and Plants in Cities.—I don't know anything sweeter than this leaking in of Nature through all the cracks in the walls and floors of cities. You heap up a million tons of hewn rocks on a square mile or two of earth which was green once. The trees look down from the hill-sides and ask each other, as they stand on tiptoe, "What are these people about?" And the small herbs at their feet look up and whisper back, "We will go and see." So the small herbs pack themselves up in the least possible bundles, and wait until the wind steals to them at night and whispers, "Come with me." Then they go softly with it into the great city—one to a cleft in the pavement, one to a spout on the roof, one to a seam in the marbles over a rich gentleman's bones, and one to the grave without a stone where nothing but a man is buried—and there they grow, looking down on the generations of men from mouldy roofs, looking up from between the less-trodden pavements, looking out through iron cemetery-railings. Listen to them, when there is only a light breath stirring, and you will hear them say to each other, "Wait a while!" The words run along the telegraph of those narrow green lines that border the roads leading from the city, until they reach the slope of the hills, and the trees repeat in low murmur to each other, "Wait a while!" By-and-by the flow of life in the streets ebbs, and the old leafy inhabitants—the smaller tribes always in front—saunter in, one by one, very careless seemingly, but very tenacious, until they swarm so that the great stones gape from each other with the crowding of their roots, and the feldspar begins to be picked out of the granite to find them food. At last the trees take up their solemn line of march, and never rest until they have encamped in the market-place. Wait long enough and you will find an old定价 oak hugging a huge worn block in its yellow underground arms; that was the corner-stone of the state-house. Oh, so patient she is, this imperturbable Nature! —OLIVER WENDELL HOLMES.

New Parks in America.—The following parks are now being or about to be formed in the United States:—Brooklyn, 500 acres; New Britain, 100 acres, B.C., $\frac{1}{2}$ acre; 350 acres; Chicago (two), 500 acres, neither of which is yet comm., and Philadelphia, 114

acres, not yet commenced. The plans for Fairmount Park, Philadelphia, have scarcely been completed yet, so that I cannot say when operations may be started there. Tompkins and Washington squares, in New York, have just been remaking. Union and Madison squares are also in course of re-construction in the same way, and I am told that the squares in Washington are to be done in a similar way soon.

New York, Sept. 28, 1871.

R. M.

Transplanting Large Trees in Paris.—Parisian horticulturists are now engaged on a transplanting experiment, on a large scale, with a view to replace the fine trees of the Champs Elysée, which war and revolution have recently destroyed. It will be the boldest attempt ever made in France in the removal of full-grown trees; and it is thought that the precautions adopted, which have necessitated a large outlay, will ensure complete success to this bold attempt to restore the pleasant groves of the Champs Elysée to their original beauty. If the result should be as expected, it will be very gratifying to see the extensive gaps among the trees of that favourite promenade satisfactorily filled up by others, in every respect equal to those destroyed.

Metropolitan Improvements.—The Metropolitan Board of Works intend to apply to Parliament for powers to effect improvements in the following localities, either by widening the existing roads and thoroughfares or constructing new ones:—Berkeley-street, and near East Smithfield, Wapping; High-street, Shore-Hitch; Old-street, towards New Oxford-street; Harrow-road, and Newington-bents. It is also proposed to widen Clerkenwell-street and effect improvements near that street and Cook's-court. Parliament will be asked in the ensuing session to authorize the construction of a sub-way under the Thames, connecting the south-west corner of the ornamental ground adjoining the Victoria Embankment, and immediately to the eastward of the Temple-bar end of the Metropolitan District Railway, and terminating on the opposite side of the river near the junction of Princes-street with the Commercial-road.

Sea Baths for London.—A project for supplying London with sea water has been suggested. It is proposed by a company about to be incorporated, to bring the water from the neighbourhood of Brighton by means of nine reservoirs and ten conduits and pumping stations. The company propose, further, to construct public and other baths, and to supply sea water to any parish or place within the limits of the metropolitan district.

HARDY CACTI.

For several years past, the hardiness of *Opuntia Rafinesquii* in the climate of London and Paris has been a subject of remark, and various persons in England and in northern France have testified to its hardiness. The fact, however, that it stands and grows well in a London back-garden, and deprived to a great extent of the sun, is as much proof as we need in that respect. This hardy species resists much greater cold than we ever have in Britain, and it is probable we shall find that half a dozen or more species of cactus are quite as hardy as it. Along the line of the Pacific Railway you see cacti abundant in some places—in districts frosty and silvered with snow when I passed over them last November, and on the flanks of the Wasatch Mountains, near Salt Lake City, deeply covered with snow during the winter. It is desirable, in gathering the small mountain plants, and in sitting down on the ground, to look well for a small, pointedly prickly cactus, with round stems, which abounds there, and which communicates a peculiarly acrid sting to all soft, fleshy parts that touch it. I gathered this in company with astрагaluses and other plants we usually term alpine. In the eastern and western States of America, very cold in winter, as everybody knows, there are three hardy opuntias—*O. vulgaris* (the common prickly pear), which goes as far north as New England; *O. Rafinesquii*, in Wisconsin and Kentucky; and *O. missouriensis*, in Wisconsin and towards the great plains. And from what one sees along the Pacific route, it is very likely a greater number of cacti go north along the Rocky Mountains' dry plains and sierras than we find on the eastern side of the continent. It is very likely we shall some day have quite a group of dwarf hardy cacti keeping company with the houseleeks on our rock-gardens, and rivalling them in hardiness. They should be planted on the drier parts of the rock-garden, on dry sunny banks, on the edges of old walls, old bridges, ruins, &c. They will also thrive on borders, but are most appropriately placed in the positions above named.

W. R.

Obsolete Names of Plants.—Some botanists seem to consider it a meritorious act to rescue a forgotten name from oblivion, and look upon such discovery as being of almost as much benefit to science as the detection of some overlooked specific character. Such authors appear entirely to forget that names are merely arbitrary terms to represent the plants to which they belong. The rule that, when a species is already known by two or more names, the earliest given of these is to be adopted, is agreed to solely as a means of attaining unanimity in nomenclature; but the revival of an obsolete appellation by which no one knows the plant is only producing, instead of avoiding, confusion, and should be discouraged to the utmost.—B. B. SYME, in *English Botany*.

THE GARDEN.

"This is an art,
Which does mend nature: changes it rather: but
THE ART IS NATURE."—Shakespeare.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, THE "GARDEN" OFFICE, 37 Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER.

The Name and Address of the writer are required with every communication, though not for publication, unless desired by the writer. Letters or inquiries from anonymous correspondents will not be inserted.

All questions on Horticultural matters sent to "THE GARDEN" will be answered by the best authorities in every department. Correspondents, in sending queries, are requested to write on one side of the paper only.

Readers who may find it difficult to procure the numbers regularly through the newsgagents, may have them sent direct from the office, at 19s. 6d. per annum, or 9s. 9d. for six months, payable in advance.

PUBLIC GARDENS.

THE PATHWAY TO NOBLE NATIONAL GARDENS.

In large cities like London, New York, or Paris, where thousands of acres are already rescued from our mighty deserts of slate and brick, the question of how to treat them so that they may be of fullest value to the public, not only as fields of health, but as schools of delightful instruction, is one of great importance. The public parks near no large city that we have seen, represent a tithe of the beauty and interest of the vegetable kingdom of which they are capable, under the system to be presently indicated. We take into consideration, first, their vast extent; second, their variety of soil and surface; third, the large sums spent annually for their keeping. Everywhere in them we see vast surfaces almost totally neglected, or only garnished with a few common-place trees; everywhere the fullest evidence that no thought is given to the production of noble, permanent, and distinctive features. Sometimes, indeed, a favourite spot in one is embellished at great expense during the summer months with tender plants, while the remainder of its surface is usually wholly uncared for. This is something like embellishing a man fluttering in rags with a costly button-hole bouquet. But the radical fault, everywhere strikingly apparent, is monotony in regard to materials used. A number of trees become popular, and they are planted everywhere in about the same proportion. Thus, we everywhere find about the same type of vegetation; and the capabilities of our parks as grand national gardens are quite undeveloped.

The system we propose, and the one certain to give us the noblest series of public gardens the world has ever seen, is to treat all the public parks and gardens of a great city as a whole, and to establish in each a distinct type of vegetation. For example, we might devote one city park chiefly to noble deciduous trees; another, suburban one, as Richmond, to evergreen forest trees; another, to the almost countless flowering deciduous trees and shrubs that are the glory of the grove and copse in all northern and temperate countries. Or we might treat the subject geographically, and have a small square or park with British trees, and shrubs, and plants; another of European, another of American, another of Siberian, and so on. This plan does not involve the removal of other types of vegetation. On the contrary, their presence would often be necessary to contrast with those to which a park or garden might be chiefly devoted. In all our parks, therefore, the improvements suggested might be carried out without disturbing any important subjects. And, even if it were determined to devote a park wholly to the vegetation of one country, no one need doubt that the highest effects could be produced by it alone who remembers what scenes we witness in our lanes and woodlands, from even four or five kinds of native shrubs and trees. We could by the system we advocate define for each superintendent in what direction his efforts should chiefly tend; give each an entirely distinct aim, and

thereby free him from paltry rivalry with his fellows in the matter of "bedding plants," &c. He could then take up a Family, Order, or Flora, and develop its beauty and variety to the completest extent of our knowledge! In the vast expanse of our public gardens, there is not one interesting and important branch of arboriculture or horticulture which we could not develop in a way hitherto unexampled. On our botanic gardens already in existence (most of them not large enough for the proper grouping and arrangement of one single family of trees, with sufficient interspaces to permit of these being seen to advantage) the system would have the best results. It would relieve our botanic gardens of the necessity of cramming every available plant or tree into a small space, and permit of their curators devoting sole attention to the many tribes of plants which require special and continual care or renewal.

Generally our present botanic gardens give no more idea of the variety, beauty, and majesty of vegetation, than the fountain basin does of the wild tossing of a wind-tortured sea. No botanic garden in existence gives any worthy expression of the vegetation of even the cold and temperate clime vegetation of Europe alone! What do we see of the beauty and character of any one large family of trees by planting them all at regular intervals over a plot, or in the various ways we see them arranged in botanic gardens? The common way with botanic gardens is well, if we have no higher object than to procure specimens to illustrate the grammar of the nomenclature men have given plants. But if our aim be to show the inexhaustible beauty and dignity of the vegetable kingdom, we must disentangle ourselves from such small notions. And, clearly, the way to do this is to treat our vast series of gardens (both botanic gardens and parks) as a whole; stamp on each some distinguishing feature—from the smallest square with a complete collection of Ivies or Hawthorns, to the noblest park adorned with the trees of a hundred hills.

Finally, though the subject suggests other points of interest, let us consider what a noble school of instruction the parks of London, or those of any other great city, might in this way become for every planter and every garden-lover. The whole might be made a colossal experimental ground, in which every question in connection with arboriculture might be thoroughly tested. In every direction distinct types of vegetation would be met with, instead of the "universal mixture" now everywhere seen, and which so soon and so thoroughly takes the eye to see no more notice of trees or plants than of any individual railing-spine round one of our squares. The contents of no botanic garden now in existence would be worthy of mention compared with the noble results we could attain in this way. It is not, like many of the changes we long for in towns, impossible to carry out from want of means. The adoption of it would at once tend to make the expenditure of every shilling spent in our public gardens go toward a valuable result, and by it we should soon have national gardens in a far nobler sense than any hitherto in existence.

THE SMOKE POISON.

WILL nobody deliver us from the perils of smoke? Every year our cities grow vaster, and the great pall of "blacks" is ever widening! To hope to arouse public attention to the magnitude of the evil, by pointing to the thousands of plants that are always perishing from it, would be hopeless, considering that its pernicious effects on our own lives do not seem to be taken the least notice of. London and all our large cities are always under its ban; but its most detestable aspects are most apparent, on those still, frosty, autumnal and winter days, which in the country are so clear and sunny. On these, there being no breeze to brush away the outpourings of the innumerable chimneys, the whole settles down in the streets like death on living men. On those days the glorious sun is darting its beams into the wide and horrid cloud, powerless to shoot a ray through its depth.

Not the least curious thing about this great but avoidable plague, is that both foreigners and natives put it down to the climate.

M. Taine speaks of the woefully-depressing influences of the climate. Doubtless there are many better; but certainly the climate of London is quite as agreeable as that of Paris or northern France. The clouds of smoke make the difference. In consequence of being contented to live in a sea of the refuse of our fires, we possess the privilege of having our fairest, stillest, winter days turned into foulest nights, in which one is stifled with vapours that would add a

THE TWO PATHS.

AMONG the many original rockworks I have seen, those shown by the accompanying cuts deserve being handed down to future ages. They show some of the foolishness which "rock-works" display. The hideous wall-like arch in the Hammersmith gem was, no doubt, originally planted with rock-plants, &c., by somebody who imagined they would grow thereon. The horizontal strata beneath the bolder cliffs in the public garden example are well worthy of study. These

"Rockwork" in London public garden.

detestable examples will serve to show what childish and stupid notions of rock-gardens have up to the present time existed in gardens. If the purblind love of the picturesquie is gratified by such abominations as these, how much pleasure may we not hope to

Rockwork in Villa at Hammersmith.

give when the true and simple way of making a rock-garden is generally adopted! The labour and the "genius" expended by the unfortunate persons in whose poetical brains such scenes as the preceding are conceived, and whose hands build them, would be precious if rightly directed. Are these "rockworks" suggestive of anything lovely in this world? Of all foolish things done in gardening that betray the trail of the serpent, this is the most foolish. A weary spinning away of the soul and emptying of the purse to produce something offensive to nature and man! With one cartload of stones a better effect could be produced in ten minutes than by all the

Single half-buried Stone surrounded by Alpine Plants.

rockworks of the above type yet created! Nay, with one stone as shown in the accompanying cut. Such a stone may be very appropriately seen peeping above the turf, near the lower flanks of the rock-garden, or where the ground is about to break into bolder rocks or strata. With a dozen stones, we succeed with our tiny rock-garden on the margin of a shrubbery.

The following illustration well explains our meaning: an irregularly-sloping border, with a few mossy bits of rock peeping from a swarming carpet of Sandworts, Mountain-pinks, Rock-cresses, Sedums and Saxifrages, Arabises and Aubriettes, with a little company of fern-fronds sheltered in the low fringe of shrub behind the mossy stones. This is a rock-garden which anybody could carry out, and which would offend nobody. As the first illustration is sketched in a botanic garden, it may be well to point out the exceeding impropriety of tolerating such scenes in a public garden even of the meanest sort! Granting that means were waiting for anything better, their presence is inexcusable. Absurdities of this kind should be removed! It were surely better to do nothing at all

than thus to sow the seeds of vicious taste in the minds of visitors to our public gardens. In some of our public and private gardens want

Rock-garden on margin of shrubbery.

of means is given as an excuse for the presence of the hideous pock-marked-potato-pit-like masses of rockwork that disfigure them. The plan now recommended is as much less expensive than these, as it is less offensive!

WALL PLANTS.

Some plants, like the wall Linaria, the Wallflower, and Snapdragon, are so fond of old walls that we see them everywhere thereon, but there is generally no adequate notion of the great number of plants that will thrive on walls. I have no doubt whatever that at least 400 species of cultivated rock and alpine plants would thrive well on old walls and ruins if sown thereon. Nor must it be supposed that a moist district is necessary, for the Pansy shown in the accompanying cut grew on a very dry brick wall at Kew—the brick wall behind the narrow border for herbaceous plants. It sprung forth at a foot or so below a coping, which prevented it from getting much or any rain, and one would scarcely have expected a Pansy to have existed in such a position. It not only did so, but flowered well and continuously. No doubt the seed fell in the chink by chance. Those who possess old brick or other kinds of old walls would do well to sow on them the seeds of various rock and alpine plants; and also where there are mossy chinks, with a slight deposit of mould, to insert small plants in autumn. The silvery Saxifrages would do well planted thus, while they might also be sown with almost the certainty of success. Leaving out the few common wall plants mentioned at the beginning of this note, the following are among the most likely to succeed of plants easy to obtain:—*Corydalis lutea*, *Arabis arenosa*, and *A. petroia*, *Draea* in great variety, *Ionopsidium aculea*, *Reseda odorata*, *Gypsophila* in variety, *Tunica Sacrifraga*, *Dianthus cerasinus*, and *D. petraeus*, *Lychis alpina*, *Arenaria balearica* (moist sides of walls), *Sedum* in great variety, *Sempervivum* in great variety, *Saxifraga* in great variety, particularly the silvery or *Aizoon* section, *Bellium* in variety, *Campanula* small kinds in variety, *Eritus alpinus*. All the above may be sown in August or September, or in spring. This short list is confined to small plants. Among larger ones the common *Centranthus ruber* (Red Valerian) and its varieties do quite as well on old walls or ruins as the Wallflower, the Stock, or the Snapdragon; but these are not well fitted for association with the dwarf alpine plants, however attractive on high walls, old bridges, ruins, &c.

Pansy on dry brick wall.

EXHIBITIONS.

FLORAL DECORATIONS.

Although the present generation is not so wasteful of time as were the Athenians of eighteen centuries ago, yet the desire for novelty seems not to have decreased in the interval. The fashion of our times exhibits an insatiable longing for the opportunity of seeing "some new thing," rather than of talking or hearing about it. The Greeks were gossips and chatterboxes, while we are sightseers. Now, if flower shows are to continue to be attractive, the necessity for novelty must be a more grave consideration with their managers than it has been of late. People will not go to see the same thing over and over again.

Horticultural exhibitions, in their widest meaning, are displays of garden products of all kinds. Now garden products may be divided into two distinct classes, viz., the useful and the ornamental, the necessary and the luxurious, the eatable and the uneatable. Of these two divisions, that which concerns the mouth is unquestionably of more vital importance than that which pleases the eyes only. Yet, as visitors go to these exhibitions to see and not to taste, it follows that, in order to render them attractive and self-supporting, those branches of horticulture which affect the inner man must not have so much prominence given to them as those branches which interest the organs of sight and smell. Hence it is that particularity for particular branches of horticulture induces people to prefer calling such exhibitions "flower shows." And here I would like to refer to the ridiculous plan which some societies have of calling themselves "horticultural and floricultural," as if horticulture were not included in horticulture.

But to return to the attractive portions of a flower show. There appears to me to be many novelties which might advantageously be introduced, and particularly as regards the application of plants and flowers to decorative purposes. Up to the present time the metropolitan societies have not gone beyond offering prizes for groupings of plants, as in conservatories, and of flowers, &c., for dining-tables, boudoir-tables, and bouquets; and in all the schedules that I have seen, the explanations of what the prizes were offered for, and of what restrictions were placed on the exhibitors, have been far from satisfactory; and, hence, to a great extent, the dissatisfaction in many cases with the award of the judges, as well as the diversities in the opinions of the different judges; for it is not an uncommon thing for the same exhibitors to compete at different shows with the same display, and for one to be successful at one show and at the other to be "nowhere," while at the following show this decision is reversed.

Take, for example, prizes offered for the decoration of a dinner-table. In order that competitors may be placed upon equal terms, detailed information respecting the following questions should appear in the schedule:—The size of the table should be fixed; the number of diners should be stated; the question of its being a dinner by day-light or after dark should be settled; if after dark, whether the table is to be lighted from the walls or ceiling, or whether by lights placed on the table, and thus constituting, and being considered as, a part of the decorations; whether fruit is necessary, optional, or prohibited; whether growing plants (which it would be better to designate as "plants with roots," as distinguished from what is commonly understood by the expression, "cut flowers") are necessary, optional, or prohibited; whether any dishes are to go on the table, or the dinner is to be served à la Russe; whether the exhibitor is, or is not, required to leave space (fifteen inches) round the margin of the table for the plates and glasses; whether a supply of plates, knives, forks, spoons, decanters, curries, ice-dishes, and wine-glasses, is required or prohibited; whether the exhibitor is expected to provide a table-cloth, and if so, of what size; what time will be allowed for arranging; whether the exhibitor will be allowed or forbidden to use any vases or other objects for ornament, which are not required for the flowers or fruit; and last, not least, let it be made perfectly clear that the prizes are not offered for the best arranged dinner-table, but for the best arrangement of garden-products suitable for the decoration of a dinner-table. The occasion upon which such a display is permitted is one specially set apart for the advancement of gardening in all its branches; it is not a fine art exhibition, but a horticultural one. Hence the arrangement and grouping of the flowers, foliage, and fruit ought always to have primary consideration; and on no account should any deficiencies in this matter be considered to have been made up for by the beauty of Elkington's stands and Copeland's dessert-plates, or Phillips' glass arches and plateaux.

This may appear to be an unnecessarily long list of doubts to be cleared up before competitors can start on equal terms; but it will only be thought so by those who have not paid much attention to the subject. All gardeners know the constantly the wording of schedules is misunderstood and differently interpreted, even in the

matter of exhibiting half-a-dozen plants; the gardening periodicals afford frequent evidence of complaints under this heading. If the managers of flower shows, and framers of schedules, are liable to cloudiness and fogginess in such simple matters, it is the less to be wondered at that their "specifications," in the more recently-introduced branch of floral decorations, are not so intelligible and explicit as they ought to be. Many a man with an eye for form can without difficulty pick out the best-shaped horse at a fair, when he would be at a loss to know how to explain to a friend all the reasons which had operated in leading him to the conclusion at which he had arrived; and he would probably look considerably aghast if some enthusiastic appreiator of his correct judgment were to suggest to him that he should "write a book about it." And I must confess that those parts of schedules affecting "table decorations," which have come under my notice, have too often impressed me with the belief either that the framers could not clearly express themselves, or else that they did not understand what they were writing about.

And now a word or two about certain novelties, which I think might well be introduced at flower shows. Floral decorations may, conveniently for my present purpose, be divided under the three headings of "personal," "domestic," and "ecclesiastical."

Commencing with *personal* decorations and giving, as in duty bound, *place aux dames*, let me mention wreaths and sprays for the hair amongst the first objects for which competition might be invited. Sprays are also sometimes worn upon dresses at evening parties. The demand for head-dresses in Covent Garden is very large. So also is the demand for coat-flowers, also called button-holes. Of these a stand containing a dozen, if nicely arranged, would well merit a prize, and much competition might be expected for stands of these.

Turning next to *domestic* decorations, the following subjects suggest themselves:—Sideboards in a dining-room, buffets or standing supper-tables, doorways, grates and mantelpieces, the end of a room for an orchestra; each of these might be suitable subjects for prizes. So also might be a portion of one of the series of long tables used at public dinners, arranged (as they so rarely are now) so that every one may see the "gentleman who is speaking."

Upon decorations *ecclesiastical* I must touch but very briefly, merely mentioning that competitions for fonts, doorways, arches, screens, scrolls, crosses, &c., if decorated with natural flowers, could not take place in a more suitable and appropriate place than at a flower show.

W. T.

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS, DOUBLE WINDOWS, &c.

In country or in town there is no more interesting amusement than the culture of plants indoors! And if so now, how much more will it be when we have in dwelling-houses the large number of plants that may be well grown therein! We have, as yet but a very imperfect knowledge of the number of species that will thrive in the dry air of rooms; there are probably thousands of the natives of hot and arid countries which will do so. Comparatively few have as yet been tried. The present is the first of a series of excellent articles from the German of Dr. Regel, of St. Petersburg, where the indoor culture of plants is carried to a degree and with a success of which we have no adequate notion in this country. This culture is yet, as far as its infancy in this country and on the Continent, though it is better understood in some parts of the Continent than with us.

Before we proceed to more special instructions concerning the culture of plants in rooms, we shall first make some general observations on those places or parts of dwelling-houses which can either be used for the cultivation of plants or which may be adorned by them in a tasteful and durable manner. Everyone who wishes to occupy himself with this mode of culture, whether the means at his disposal be great or small, should be careful not to select windows which face the north, as in such a case it is absolutely vain to expect that the attempt will be attended with any permanent or satisfactory results. The best aspect is a south one, where the sun has free access during the entire day, as rooms are the better adapted for this mode of culture in proportion to the length of time they remain under the influence of the solar rays. In towns suitable houses are seldom to be obtained; but where a choice can be made, one should be selected which faces the south, east, or west, so that at least for some part of the day the sun, even when he is nearest the horizon in winter, may shine freely upon it. The longer he can do so the better adapted the house will be for room culture. An excess of solar light can be regulated by means of shading, &c., while a deficiency of it cannot be supplied by any means whatever. Whoever desires to convert a room into a sort of winter-garden, by means of suitable ornamental plants, should choose for this purpose a corner room

which has windows on both sides, and is more or less exposed on both sides to the sun. The larger and higher the windows, and the lighter the room, the more favourable will it be for the culture of plants. Light-coloured paper, or light colouring on the walls, is also advantageous in this respect. Dwelling-rooms, which are generally warmer and more dusty, are less suitable for this kind of culture, and for decoration with evergreen stove-plants, than reception-rooms, the temperature of which in winter averages from 55 deg. to 60 deg. Fahr. However, some kind of vegetation will be found to thrive in almost every kind of apartment, and in those that are kept dry we may have numbers of Mesembryanthemums and other succulents, if nought else. Corridors and frost-proof chambers, which are more useful for wintering greenhouse plants, should be light and sunny, and should moreover be furnished with thermometers, so that their temperature may be known. During continuous cold weather they should be heated just to the degree which will exclude frost. Care should also be taken to guard against the admission of cold draughts when opening the doors in frosty weather. In very severe climates double doors will be necessary. By not attending to these last two particulars, entire collections of in-door plants are often lost in a short time.

(To be continued.)

THE FLOWER GARDEN.

NOTES MADE IN "THE TIME OF ROSES."

By S. REYNOLDS HOLE.

EVERYBODY knows that, no long time ago, a public notice was set up by one of the stewards upon an Irish course, warning the world, that if the horses were not punctually at the post, the races would proceed without them; but only some of us know that, in the season by courtesy called summer of 1871, we rosarians, who race for the Queen's Plates, that is, for the silver cups of Her Majesty the Queen of Flowers, have been rose-showing without our roses. We have been racing on our hacks, and just as the spectators were thronging from the ground, our beautiful thorough-breds came upon the scene.

I mean that, with some few exceptions in our southern and western shires, the best flowers have bloomed on our trees after the wars of the roses were lost and won. A severe winter, followed by an ungenial spring, so crippled the weak and kept back the strong, that in our midland and northern districts hardly a rose appeared in its integrity before the second week in July; and in the flowers brought to our exhibitions from a milder climate, there was seen only here and there in its full development the grace and glory of the rose. Once checked in its growth, once chilled by vernal frost, no bud ever reaches perfect rosehood. It may produce an attractive flower; but in size, or symmetry, or colour, or foliage, there will be defect. The bloom which Cœlebs cuts for his betrothed, and Benedict for his bride, the rose which is four inches in diameter, and has not a petal sullied or out of place, has known no sickness nor stay. And so it has happened that we have gone abroad to the shows with our first roses more or less discoloured and deformed, and have surveyed at home an abundance of perfect flowers. The hay which we have taken to market was in quantity small and in quality coarse, but the "edish" has been magnificent.

Rose-growers of England, who live at home at ease, you have not, I can assure you, an adequate appreciation of the anxieties of those who go forth with their blooms in boxes. For two or three days before a rose-show, the exhibitor is "roving for ever from flower to flower" (gay pastime for bees, and butterflies, and lithe young lovers of the rose, but trying to parties who are rising fifty, and weighing sixteen stone), wondering which will be ready, and which will not; now shading to retard, now blowing to educe, a bloom; collecting and culling his moss; arranging his boxes; writing names upon cards; and, on the eve of the exhibition, cutting his roses. See him! with a flower in his right hand, and a flower in his left hand, and a flower held between his teeth, and with his two eyes vainly essaying to gloat on twenty others at once—see him, with the last night's ink upon his fingers, and last night's beard upon his chin, for he has risen at three in the morning, and come out much as he rose—see him, tearing backwards and forwards, to and fro, as though he had backed

himself to fill a thousand boxes in a thousand hours—see him, now standing in cold despair before that *Charles Lefebvre*, which yesterday was a miracle, but now returns his stare with an "eye" about the size of a sixpence, and now flushed with a smile, roscate, as he sees for the first time a glorious *Pierre Notting*, pendent in purple beauty beneath its liberal leaves.

And then the journey: the horrible apprehension which always postpones itself until you are three miles from home, that you have left something, you know not what, behind; the agonising possibility of being too late for the train; the stone deafness of guards and porters to your shrieks of "keep level," and their constant appearance at either end of your boxes, in the position of persons playing see-saw; the cabman, who does not seem quite sure as to his route, and the horse who does not seem quite sure as to his footing; the unpacking, the jostling, the staging; the well-meant but maddening queries of the bystanders flocking around, "Isn't that *Marie Beauman* too far gone?" and, "Haven't you got a better *Maréchal Niel?*?" Then, finally, "the waiting for the verdict"—not always Solomon's, not always just and wise.

Wherefore, remembering these solicitudes, I was glad to rest in my bower, and surveying thence my roses thankfully, now invite you, my reader, to share my thoughts.

First, in my annual astonishment and admiration at the supreme beauty of the rose—in my wonderment why this flower should hold such an excellence above all flowers as we find in no other genus or species of created things. There prevails, by unanimous assent, no such superiority among the nations, in the animate or inanimate world. We English are fully convinced that we are the cream of creation; but the verdict must be "Not proven," so long as the neighbours fail to see our close affinity to the cheese. *Aesop* and others have crowned the lion king. There is to my eyes more of majestic dignity in the horse, more of beauty in the antlered monarch of the waste, greater powers of administration in the subtle wisdom of the fox. Nor have I observed any recognition of royalty in the behaviour of the other animals before the so-called king of beasts; but have noted, on the contrary, in the menagerie of Wombwell a levity of conduct, more especially striking in the deportment of the monkeys, which no subjects could have exhibited around and before the throne. The diamond, you say, outshines all other gems: there are some who love the emerald and the opal more. But we are all at one, florists or not, as to the Royal Supremacy of the Rose. I will make no comparisons. No true gardener compares one flower with another, loving all too well to disparage any; but while he finds in each, from a *Mosotis* to a *Magnolia*, enough and more than enough of beauty to exhaust his power of appreciation, he will tell you that their Queen is the Rose. We are loyal to a man. We may and do differ as to the *Belle of the Court*; whether *Lælia* or *Dipladenia*, *Allamanda* or *Ivora*, *Stephanotis* or *Eucharis*, *Erica* or *Hedaroma*, *Lily* or *Viola*, be fairest of the fair ladies-in-waiting, but we have no dissension in whose hand to place the sceptre.

(To be continued.)

The American Sweet Water-Lily (*Nymphaea odorata*).

These pleasant hills are not of the monotonous if rich prairie. These English-like hedgerows that border good winding-roads have little in common with those of Western Canada, where you can never go anywhere but in a painfully straight line. These pretty villages have not the primly meanair of the young American town, but a grateful, home-like look, and have little gardens and large trees. These quiet village-greens instantly remind one of the pleasantest parts of a small island on the other side of the Atlantic. Such were my thoughts last autumn as a manly-looking young fellow (as he sat by me and talked I could scarcely realise his belonging to a people with another name) drove me, by pleasant rolling woods and large, silvery, pine-fringed lakes, to Mr. Hunniwell's charming place at Wellesley, Massachusetts. New England indeed, but very like Old England, with the exception perhaps of the golden rods and asters, that make such an effective mixture of blue and gold in the copseys and by the roadsides. Suddenly we came to a lake, that shone like steel under the clear Indian-summer sun, and ran far back to slopes and bays, guarded by hosts of funeral-looking pines. Here and there on its bosom, far and near, were dotted beautiful large water-lilies, white as snow, like fairy white-winged ships alone or in little fleets, each surrounded by a

fotilla of green boats. The English water-lily? No, but very like it. It is the sweet American water-lily, so like *Nymphaea alba* that in the distance one thinks it our own queenly water-lily. *Nymphaea odorata* differs from our own white water-lily in being sweet-scented, and in having narrower petals, but the flower is quite as fine, or finer, measuring as much as five inches and a half across, and the leaves large and handsome. I know no plant more worth our attention, more worthy of a place beside our own water-lily, or of naturalisation in our ornamental waters.—*Field.*

Dipsacus laciniatus.—The subject of our illustration is a biennial plant, a native of Europe and Siberia, as easily raised as the common fullers' teasel, and a very effective plant, quite distinct in aspect, too, from the things usually seen in our flower-gardens. It is useful for grouping with the freer-growing plants like the castor oils, &c., or for filling up vacancies in groups of hardy perennials with fine foliage, or for placing a few feet within the margin of a shrubbery or mass of American plants. The treatment given to a half hardy annual will suit this *Dipsacus* perfectly, and it may be

Dipsacus laciniatus.

placed out with the earliest bedding plants. It is hardy enough, but as it is only an annual or biennial, its hardiness does not save us the trouble of raising it annually; so it may as well be raised with the half hardy bedding plants and the like. The foliage is usually fuller and larger halfway up the stem than is represented in our illustration. It is one of the most valuable and easily raised of the hardy plants frequently, but not happily, termed sub-tropical. The plant figured was sketched in Hyde Park this year.

The Wild-Garden.—When on a botanising excursion in the west of Ireland lately, I looked in at Rockingham, near Boyle, where some matters relating to the wild-garden pleased me much. Adjoining the garden, there is a low fence wall, built with brick. It is a kind of sunk fence, one face of the wall only appearing, the other being covered with earth, in consequence of the ground inside being considerably higher, which causes the side seen to be always damp. From one end to the other, it was densely covered with *Asplenium Trichomanes*, which had fronds upwards of a foot in length in many instances. The effect produced by such a mass of this elegant fern,

growing with such luxuriance under the circumstances described, seemed to me almost magical. The tops and portions of the faces of the garden walls were covered with masses of *Grammitis Ceterach* in many places, which, the gardener stated, they had constantly to eradicate, in order to keep the trees clear of it. Another pretty and partly natural object attracted my attention in the domain of Rockingham, namely, a bridge built over an arm of the great lake there, with water-worn limestone, which abounds in that neighbourhood. The ends of the slabs of stones were only hammered square, so as to make them fit firmly together; both faces were left in their curious, undulating, natural state; besides, the parapets and coping were of the same material. This bridge, covered with a beautiful drapery of ferns, and with the natural projections of the stones appearing at intervals among them, had a very picturesque and pleasing effect, such as I believe could easily be imitated in the making of artificial bridges in wild-garden scenery; hence one of the reasons I made a note of it. When at Sligo, I visited the domain of the late Right Hon. John Wynne, who was himself a good Irish botanist, as well as a lover of horticulture. I found he had been in the habit of introducing many American and other ornamental bog-loving plants through his extensive and naturally-beautiful domain. I have never before seen such plants as *Gaultheria Shallon*, *G. procumbens*, the *Pernettyas*, &c., growing in so natural a condition among the long heath and mosses as they do there. I expected to find *Epigaea repens* had also been tried, but could see no trace of it, though I have no doubt that that lovely plant would do as well there as it does in the Canadian forests.

Glasnevin.

D. MOORE.

PLANTING HARDY ORCHIDS, CHOICE ALPINE PLANTS, &c.

THERE is a mischievous or rather murderous way of planting almost every kind of small plant, which is particularly regrettable in the case of hardy orchids, which have roots easily injured, and of all rare hardy plants. I refer to the making of a hole for the plant, and after a little soil has been shaken over the roots, pressing heavily with the fingers over the roots and near the neck of the unfortunate subject. What is meant will be understood from fig. 2, if the reader assumes there is a little soil between the fingers and the roots. Where the roots are not all broken off in this way, many of them are mutilated; or

those near the collar of the plant are thrust deeper into the earth. Not unfrequently plants perish from this cause. The right way is, after preparing the ground, to make it firm and level, and then make a little cut or trench, as in fig. 1. The side of this trench should be firm and smooth, and the plant placed against it, the roots spread out, and the neck of the plant just at the proper level, as in fig. 1. Then a good deal of the fine earth of the little trench is to be thrown against the roots, and as much lateral pressure applied as may be necessary to make the whole quite firm. Once the subject is carefully planted, as much surface-pressure as you like may be given. In this way not a fibre of the most fragile plant will be injured. This, of course, only applies to subjects not planted with balls, and, without balls, is the best way to plant.—W. R.

Ivy Borders.—Well aware of the many positions in which these may be used when needed, and that many will lately be the opportunity, they produce the verdant carpet of turf sufficient, and so it is, if the subjects fill the bed properly and come flush to the margin; but, with the bare earth more conspicuous than the bedding-plants, as is often the case early in the summer, effects the greatest improvement. Next to hardy ivy, the ivy which grows a little way off, the leaf of the earth, divided by the ivy, and the leaves placed above it, a whole scenario was furnished. Ivy again deserves far more attention than they at present obtain, and they may be used in scores of positions where they are never seen. The best kind is the Irish; but where many edgings are made, it would be very desirable to produce some variety by using other healthy green-leaved kinds; and the variegated ones, too, should be attractive, though no claim of theirs can ever equal the unmatched verdure of the Irish ivy in its natural state. Be it noted, that all other leaves of our hardy plants will grow out on frosty stains.—W.

Window Gardening for Young Ladies.—Don't plant yourself in window in curl papers. By careful choice of situation and attention to aspect, young ladies may, by means of window gardening, successfully cultivate every variety of the *sheepeye* (*Ovis canadensis*), and convert *cocoons* from the single to the double variety, with great success.—*Punch's Almanac*.

THE BOG-GARDEN.

THE bog-garden is a home for the numerous children of the wild that will not thrive on our harsh, bare, and dry garden-borders, but must be cushioned on moss, and associated with their own relatives in moist peat soil. Many beautiful plants, like the Wind Gentian and Creeping Harbell, grow on our own bogs and marshes much as these are now encroached upon. But even those acquainted with the beauty of the plants of our own bogs have, as a rule, but a feeble notion of the multitude of charming plants, natives of northern and temperate countries, whose home is the open marsh or boggy wood. In our own country we have been so long encroaching upon the bogs and wastes that some of us come to regard them as exceptional tracts all over the world. But when one travels in new countries in northern climes, one soon learns what a vast extent of the world's surface was at one time covered with bogs. In North America day after day, even by the margins of the railroads, one sees the vivid blooms of the Cardinal Flower spring erect from the wet peaty hollows. Far under the shady woods stretch the black bog-pools, the ground between so shaly that you move a few steps with difficulty. One wonders how the trees exist with their roots in such a bath. And where the forest vegetation disappears, the American Pitcher plant (*Sarracenia*), Golden Club (*Orontium*), Water Arum (*Calla palustris*), and a host of other handsome and interesting bog-plants cover the ground for hundreds of acres with perhaps an occasional slender bush of Laurel Magnolia (*Magnolia glauca*) among them. In some parts of Canada, where the painfully-long and straight roads are often made through woody swamps, and

where the few scattered and poor habitations offer little to cheer the traveller, if a lover of plants, he will find conservatories of beauty in the ditches and pools of black water beside the road, fringed with the sweet-scented Button Bush, with a profusion of royal and other stately ferns, and often filled with masses of pretty *Sagittariae*.

Southwards and seawards the bog-flowers become tropical in size and brilliancy, as in the splendid kinds of herbaceous *Hibiscus*, while far, north, and west, and south along the mountains, the beautiful Showy Moccasin flower (*Cypripedium spectabile*) grows the queen of the peat bog and queen of hardy orchids. Then in California, all along the Sierras, you see a number of most delicate little annual plants growing in small mountain bogs long after the plains have become quite parched, and annual vegetation quite disappeared from them. But who shall record the beauty and interest of the flowers of the wide-spreading marsh-lands of this little globe of ours, from those of the vast wet woods of America, dark and brown, and hidden from the sunbeams, where the fair flowers only meet the eyes of water-snakes and frogs, to those of the breezy uplands of the high Alps, far above the woods, where the little bogs teem with Nature's most vivid jewellery, joyous in a

bright sun, and dancing in the breeze? No one worthily, for no one knows. For many mountain-swamp regions are as yet as little known to us as those of the Himalaya, with their giant Primroses and many strange and lovely flowers. One thing, however, we may gather from our small experiences, that many plants commonly termed "Alpine," and found on high mountains, are true bog-plants. This must be clear to anyone who has seen our pretty bird's-eye Primrose in the wet mountain-side bogs of Westmoreland, or the Bavarian Gentian in the spongy soil by Alpine rivulets, or the Gentianella (*Gentiana acaulis*) in the snow ooze. We enjoy at our doors the plants of hottest tropical isles, but many wrongly think the rare bog-plants, like the minute Alpine plants, cannot be grown well in gardens. Like the rock-garden, the bog-garden is rarely or never seen properly made and embellished with its most suitable ornaments. Indeed, bog-gardens of any kind are very rare, and only attempted by an individual here and there, who usually confines them to the accommodation of a few plants found in the neighbouring bogs. I will now proceed to point out how these may be made with a certainty of success.

In some places naturally boggy spots may be found which may be readily converted into a home for some of the subjects to be named hereafter. But in most places an artificial bog is the only possible one. It should only be made in a picturesque part of the grounds. It may be associated with a rock-garden with good effect, or it may be in a moist hollow, or may touch upon the margins of a pond or lake. By the margins of streamlets, too, little bogs may be made with excellent taste. A tiny streamlet may be diverted from the main one to flow over the adjacent grass—irriga-

tion on a small scale. No better bog than this can be devised, and none so easily made. Another very good kind could be made at the outlet of a small spring. It was in such little bogs I found the Californian Pitcher plant in dry parts of California, where there were no real bogs. In some of these positions the ground will often be so moist that little trouble beyond digging out a hole to give a different soil to some favourite plant will be needed. Where the bog has to be made in ordinary ground, and with none of the above aids, a hollow must be dug to a depth of at least two feet, and filled in with any kind of peat or vegetable soil that may be obtainable. If no peat is at hand, turfy loam with plenty of leaf-mould, &c., must do for the general body of the soil; but as there are some plants for which peat is indispensable, a small portion of the bog-bed should be composed entirely of that soil. The bed should be slightly below the surface of the ground, so that no rain or moisture may be lost to it. There should be no puddling of the bottom, and there must be a constant supply of water. This can be supplied by means of a pipe in most places—a pipe allowed to flow forth over some firmly-tufted plant that would prevent the water from tearing up the soil.

THE BOG-GARDEN.

RECENT FLOWER-GARDENING.

TO THE EDITOR OF "THE GARDEN."

Sir,—Our old nursery song says—

" Mary, Mary, quite contrary!
How does your garden grow?
With silver-bells, and cockle-shells,
And houseleeks all of a row."

May not this warning rhyme of our infancy go down to posterity with "Miss Muffet who sat on a tuffet," and was alarmed by a "spider who sat down beside her" (which shows the youthful mind how foolish it is to be afraid of harmless insects, and so "lose their curds and whey"); or, again, with "the Old Woman who lived in a shoe" (which in its moral is Malthusian)? Can we not, sir, extract a moral and preach a short sermon on this piece of wisdom of our ancestors? I think so. I think that a clever person might make a homily which would even reach Mr. Ayrton's heart, and although his name is most certainly not "Mary," he is decidedly "contrary" in many ways. The line referring to "houseleeks all of a row," obviously refers to a recent monstrosity in gardening to be seen to any extent in Hyde Park and elsewhere. There, for the first time, have I seen houseleeks, which in their natural grouping are like a beautiful irregular constellation of suns, put "all in a row" on mud, round flower-beds, without an inch wrong between them. This is "taming nature" with a vengeance. We must remember, however, that the great verse quoted at the head of this letter was composed more, probably, than one hundred years ago, when there were gardens—there are none now,—and when houseleeks were not put in a row. Looking at it in that light we may say with the immortal Chiggle, as quoted by an American gentleman in "Martin Chuzzlewit," that "it was a pre-diction, cruel smart." We have not come to cockle-shells yet in our public gardens, but we must wait and hope; we shall not be long without them if we go on steadily developing in our present direction.

I most strenuously protest, sir, *in toto*, against this new ribbon-gardening, as being utterly inartistic, utterly false to nature, and, three times out of four, utterly false in colour. Their arrangement is either empiric or traditional. As an example of the traditional method, look at the ordinary arrangement of scarlet geraniums and yellow calceolarias with an edging of blue lobelia. Is that beautiful? I, for my part, cannot undertake to say; but it is certainly fashionable. I should be disposed to ask if the present head-dress of the ladies is beautiful, and I should receive the stale, stupid, old answer that there is no disputing about tastes. I say that there is such a thing as good taste and bad taste, and that the further you depart from nature the nearer you get to bad taste. If a lady choose to wear her hair *au naturel*, or to loop it up in a natural and sensible way, she is in good taste, and will find that her head looks like that of the Venus de Medici; if she makes it the size of a bushel-basket with false hair, she is in bad taste, though she may be in fashion. So with flowers planted in rows: nature never plants in rows. It were better to get a strong man to cast a bushel of potatoes about, and to plant where each falls. However, sir, as I have cast enough potatoes about for this week, I will leave off before one of them comes back on me. I hope soon to begin my second parallel against the monstrous fortress of fashion; at present I have only broken ground.

HENRY KINGSLEY.

NOTES AND QUESTIONS ON FLOWER-GARDENING.

Aster longifolius (var. *formosus*).—There is perhaps no genus that, while containing a number of valuable autumn flowering border-plants, contains more species of a weedy and useless character than the large group bearing the generic title of *Aster*. Next to *A. bessarabicus*—sometimes erroneously called "grandiflorus"—in fact, on a par with it as to beauty, stands the above-named species, or rather variety. I am scarcely prepared to say that its specific title of "long-leaved" is a very appropriate one, as this character is not at all marked either in the radical or caudine leaves; and were it not that it has been referred to this species on the very best authority, I should have been disposed to question it. Under any circumstances, it is a wonderfully beautiful variety, and one that no selection of herbaceous plants should be without. What the

original species is like I know not, beyond the fact of its being of a tolerably ancient date, and described as having white flowers and growing three feet high, whereas this has a densely arranged ray of florets of the most lovely warm rose-coloured tint imaginable; but beyond this it has another quality, and one that would even render it valuable for conservatory decoration, and that is, it might be made to fill an hiatus between the ordinary summer denizens and the Chrysanthemums, or still better, perhaps, in association with the latter. In order to grow it for this purpose, about the month of April the young shoots should be removed and placed in a slight bottom heat. They will strike freely and rapidly after they are established, and once pinched back they may be shaken out of the pot and separated—each plant being planted in a sunny situation, say twelve inches apart, receiving, of course, a good watering immediately after. They will soon take to their new quarters, and by the month of September, or the beginning of October, each of them will form a pyramid about fifteen inches high and twelve inches through at the base, covered with bloom from top to bottom, and with the still further advantage that all the blooms expand together. If left carefully, and placed in moderately sized pots, they may then be removed to the conservatory or greenhouse, where their plebeian origin will be lost sight of in admiration of their intrinsic beauty. I received this same Aster last summer, under the name of "Madame Sognace," which is, no doubt, of Continental origin. I have grown it for some four or five years, and have given it the above name. In conclusion I might add, that when grown undisturbed for two or three years, it attains a height with us of nearly three feet, and gets bare below, thus detracting from the beauty it presents when cultivated as I have above described.

Botanic Gardens, Hull.

J. C. NIVEN.

Ampelopsis tricuspidata.—Of this remarkable and lovely plant it is wholly impossible to speak too highly. Without doubt, it is one of the most desirable of all climbers for a rock, wall, tree, or wooden fence. It requires no fixing or nailing, but attaches itself perfectly close by means of short filaments (tendrils), which expand at their ends into a star-like group of suckers, scarcely removable from the surface, to which they most tenaciously cling. The roundish leaves are densely imbricated, lapping over each other, often 3 inches to $3\frac{1}{2}$ inches in diameter. In spring and summer they are of a lively citrine colour, changing in autumn to the most luminous deep crimson, but the portions lapped over remain colourless. Its growth is most rapid, and it bears exposure to the fiercest rays of the sun, and braves the winds and frosts of winter; it rarely requires pruning, as all portions cling close to the surface. The wonderful mass of rich and vivid colour which it produces all through October and part of November, is truly glorious. This species is far more desirable than *Ampelopsis heteroclita*, or Virginia creeper, the leaves of which, immediately they attain their crimson hue, and, often when still green, are scattered by winds or frosts; those of *A. tricuspidata* are retained longer than those of most climbers. It is deciduous, like all the family of vines, and the flowers are inconspicuous. One of my specimens covers a considerable portion of the lofty stone wall of the fern-house and brick buttress (which face south-west and west), and when seen from a distance associated with the scarlet-berries of the *Pyracantha* it has a truly marvellous effect. It is certainly one of the most important acquisitions ever made to our series of hardy climbers, and does honour to the memory of the late Mr. John Gould Veitch, who introduced it from Japan. Cuttings of it strike readily.

Glen Andred.

E. W. COOKE.

The *Verbena* in America.—I see, by English papers, that cultivators on your side of the Atlantic lament the difficulty of obtaining a healthy young stock of this useful bedding plant. In America the *Verbena* is grown by hundreds of thousands, as every cottage plants a dozen or so of it each year; and it is surely better by far to subject them to the treatment you will give you. The proper way of propagating them is to come across, with say three or four small healthy plants; one plant would yield all the cuttings required for stock, if they did not amount to more than a few thousands of one variety, but plant, say three or four, to make sure, in any open rich spot in the kitchen-garden or reserve-ground. Plant early in May. A moderate frost will injure them if hardened off properly before turning out. They will require no more attention beyond being staked up, and supported by thin sticks, and the stems being tied in pairs, so that they should be from two to four feet across, and rooted from all the first-made joints. Cut them close down to the ground, and throw over what remains a little fine rich soil, after loosening the ground with a fork, and if very dry giving a good soaking of water. This last would, however, not be often necessary in England. In a few weeks' time the old plants will be covered with nice soft young shoots, which will be just right for cutting. As regards propagating, however, I can only say that the best way is to take cuttings of the only thing to keep in mind being to have the houses or frames in which they are placed as cool as possible, and to afford shade if required. We strike our cuttings in clean sand placed on propagating-benches, and our climate is usually too hot for such cuttings until about the end of September. In England, however, the nights are cool earlier in the season. This year our first batch of cuttings was potted off in five days from the time of getting in the cuttings, and they were all growing away in eight days to root. We put them in two-inch pots, place them in a house, shade them for a few days, and then let them be open night and day, unless in very severe weather, keeping the temperature rather below 40 deg. than above that point on cold nights. If required, several

cuttings may be taken from each plant by November, and others at a few weeks' interval, until planting-out time, the latest batch being the best for stock plants. We strike the cuttings in winter and spring in a night-temperature of 50 deg., and place them as soon as potted in some cold house. Never let them get very dry; dust with sulphur if a spot of mildew appears, fumigating with tobacco once or twice a week. This latter is very essential. To it in a great measure, I owed my success in cucumber-growing ten years previously to my leaving England.—JAMES TAPIRIS, South Amboy, New Jersey, United States.

INSECTS, BIRDS, DESTRUCTIVE ANIMALS, ETC.

HURTFUL INSECTS.

No one will dispute that those whose business or pleasure it is to cultivate a garden would be the better of some knowledge of the insects that prey on its ornaments or products. The amount of ignorance that prevails on the subject of insects is surprising. Frequently we find all insects regarded as alike noxious. Were the whole class under trial before the majority of persons, the verdict would infallibly be that of the Scotch jurymen, "Hang them a'." Not many weeks since, as we passed an individual digging, we saw him suddenly step out, and bring his foot down with crushing emphasis upon a poor beetle that caught his eye. "Why did you do that?" said we. "It is a black beetle" was the reply, as much as to say it is a condemned outlaw. We turned upon him and were about to say, "That beetle was one of your friends; its mission was to prey upon the grubs and slugs that destroy your produce. For one that you can kill, that beetle would have consumed hundreds." But ere we had opened our lips, we saw from the expression of his countenance that to undeceive him, and extract from his mind the rooted prejudices which had prompted the action, would be no easy matter, so we saved ourselves the trouble. But if we are hopeless of *him*, we expect much good from making known in a paper like THE GARDEN all the important facts in connection with the insects destructive to vegetation, and the best modes of preventing their ravages so far as the present state of our knowledge will permit. It is our intention to figure every injurious species in its various stages, and thereby lead to a much more general knowledge of the subjects themselves. Entomology in England does not form part of any course of study. On the Continent there are Professors of Entomology, and in America (where it cannot be said that the practical money value of any commodity, whether goods or knowledge, is of no account) there are paid State Entomologists, whose office it is to devote themselves to the study of the hurtful insects of the State to which they belong, and to supply information regarding them to its inhabitants, by answering queries or otherwise. But although with us neglected, the study of our hurtful insects is a very important subject. The more we learn the more we see that our property often lies at their mercy; and, as has been well proved in America, it would be good economy in the long run to be at the expense of obtaining and diffusing knowledge of their habits, and of the best modes of preventing their ravages. Although no effort is made here to supply this want, it ought, nevertheless, to be supplied; and as men become wiser, we may reckon that it will be supplied. Meantime, we are determined to see what the press can do to remedy wants in this way. To assist us in the work we thus undertake we solicit the co-operation of our readers and subscribers, begging them, whenever they meet with any noxious insects, to transmit them to us for study and elucidation. We shall not spare expense where necessary for the exact portraiture of every species where required; and as we hold it useless to do work already thoroughly well done by others, we shall avail ourselves of their labours, and they shall, in all cases, be duly acknowledged. The Entomological Department of THE GARDEN will be under the care of Mr. Andrew Murray, F.L.S., whose most instructive and useful collections of insects illustrating economic entomology, at the South Kensington Museum, are a sufficient guarantee, if none other existed, of his peculiar fitness as a guide in this matter.

Remedy for the Apple Maggot.—The following American remedy for this terrible pest to fruit-growers is the most successful yet made known, and well deserves the attention of our fruit-growers. We find it fully and well described by W. Riley, in *Moore's Rural New Yorker*. It is known as the bandage system:—"This is best accomplished by a bandage fastened around the trunk of the tree below the branches, so as to intercept the worms. The natural habit of the worm is to spin its cocoon under the loose bark of the tree upon which it was born, and the philosophy of the bandage-system is, simply, that the worms in quitting the fruit, whether while it is on the tree or on the ground, in search for a cozy nook in which to spin up, find the shelter thus afforded just the thing, and in ninety-nine cases out of a hundred they will accept of the lure, if no other more enticing be in their way. Hay bands have been used for this purpose, but cloth of one kind or another, tacked to the tree or fastened with

string, has advantages over the hay bands, as, when taken from the tree, it can be passed through a wringer, or steeped in hot water, and the insects may thus be more expeditiously destroyed, and the cloths used again. They must surround the tree below the branches. Every man must, of course, decide for himself, according to the extent of his orchard, and the facility with which he can procure rags or cloth, whether they or the hay bands will be the cheapest and most expedient. A good bandage, ready made, is greatly needed in the country, and if some enterprising firm would manufacture canvas strips about six inches wide, lined on one side with four inches of tow, cotton wadding, or some other loose material, and would put it upon the market at a reasonable price per yard, there would be an unlimited demand for it. Such strips would last for years, and could be cut of any desired length, drawn around and tacked. As regards time, the best advice that can be given is to have the bandages on the trees about a week after the first Wilson's Albany strawberries are ripe. It is of no use to put them on earlier with a view to entrap the moths, as I am convinced that they cannot be entrapped in sufficient numbers to make it pay. The bands should be removed, and the insects destroyed, at least once a fortnight from this time till the apples are all off the tree. Of course the bandage-system is a preventive measure, not a remedy, and the beneficial effects of this system will not be felt till the year following."

Rabbit-proof Plants.—The following list of plants reported to be avoided by rabbits is prepared from notes in the *Field*. Perhaps some of our readers may be able to add to them, and perhaps others will have found some of the present list anything but "rabbit-proof":—

Trifolium	Scilla	Elder
Iris	Woodruff	Ligustrum vulgare
Winter aconite	Monkshood	Symporicarpus racemosus
Narcissus	Muscari	Yucca gloriosa
Asphodelus albus	Roses	Berberis Darwinii
Solomon's seal	Primrose in var	Syringa persicae and vul-
Lily-of-the-valley	Arabis	gars
Gentian (ground)	Anemone coronaria	Weigela rosea
Euchia	* japonica	Deutzia scabra
Columbine	Aubrieta	Ruscus aculeatus
Poppies	Violets	" racemosus
Honesty (Lunaria)	Pansies	Lycium barbarum
Phlox in var.	Canterbury Bell	Androsaceum officinale
Periwinkle (large and small)	Hollies	Hibiscus syriacus
Lilac (common orange and white kinds)	Mahonia aquifolium	Acacia sinuata
Dog's-tooth violet	Common and Irish yews	Cineraria maritima
Lobularia	Lonicera in var	Stachys lanata
		Euonymus

Destroying Grasshoppers.—An Adelaide newspaper recommends the following method of destroying the grasshoppers, which in some seasons commit great depredations in various parts of the colony:—"The plan is to sow borders or rows of the common larkspur in gardens; in vineyards it might be sown between the vines. The larkspur has a very pretty flower, and the leaf is so green that it attracts the grasshoppers at once, and, when eaten, is sudden death to them. I have seen them lying dead by thousands under the larkspur borders in the gardens in Adelaide." The writer adds that he has adopted this plan for years with much success. If this be so, what good news for the Mormons, who have been almost reduced to poverty by grasshoppers during the past few years.

The Woodpecker.—An Adelaide newspaper recommends the following method of destroying the grasshoppers, which in some seasons commit great depredations in various parts of the colony:—"The plan is to sow borders or rows of the common larkspur in gardens; in vineyards it might be sown between the vines. The larkspur has a very pretty flower, and the leaf is so green that it attracts the grasshoppers at once, and, when eaten, is sudden death to them. I have seen them lying dead by thousands under the larkspur borders in the gardens in Adelaide." The writer adds that he has adopted this plan for years with much success. If this be so, what good news for the Mormons, who have been almost reduced to poverty by grasshoppers during the past few years.

If this be so, what good news for the Mormons, who have been almost reduced to poverty by grasshoppers during the past few years.

The Money-Tree.—The speculation has sometimes crossed my mind, in that dreary interval of drought which intervenes between quarterly stipendiary showers, that Providence, by the creation of a money-tree, might have simplified wonderfully the sometimes perplexing problem of human life. We read of bread-trees, the butter for which lies ready churned in Irish bogs. Milk-trees we are assured of in South America, and stout Sir John Hawkins testifies to water-trees in the Canaries. Boot-trees bear abundantly in Lynn and elsewhere; and I have seen, in the entries of the wealthy, hat-trees with a fair show of fruit. A family-tree I once cultivated myself, and found therefrom but a scanty yield, and that quite tasteless and inedible. Of trees bearing men we are not without examples; as those in the park of Louis XI. of France. . . . Not to multiply examples, I will barely add to my list the birch-tree, in the smaller branches of which has been implanted so miraculous a virtue for communicating the Latin and Greek languages, and which may well, therefore, be classed among the trees producing the necessities of life—venerable *donum fatalis virga*. That money-trees

existed in the golden age there want not prevalent reasons for believing. For does not the old proverb, when it asserts that money does not grow on every bush, imply *a fortiori* that there were certain bushes which did produce it? Again, there is another ancient saw to the effect that money is the root of all evil. From which two adages it may be safe to infer that the aforesaid species of tree first degenerated into a shrub, then absconded underground, and finally, in our iron age, vanished altogether.—J. R. LOWELL.

THE ARBORETUM.

THE YELLOW PINE.

PINUS PONDEROSA (DOUGLAS).

This is one of the noblest of the trees that make up the great fir forests of the West, and of which the merits and importance are very insufficiently known in this country. It not only thrives in the genial climate of the mountain slopes of California and Oregon, but also spreads far into the arid desert towards the east, and crests the mountain tops in the Utah region, spreading from the Colorado River far and wide throughout the Rocky Mountains, its northern limit being as yet undetermined.

"Near or distant," says Dr. Newberry, in describing the journey of his party from the Pitt River to the Columbia, "trees of this kind were nearly always in sight; and in the arid and really desert regions of the interior basin, we made whole days' marches in forests of yellow pine, of which the absolute monotony was unbroken either by other forms of vegetation, or the stillness by the flutter of a bird or the hum of an insect. The volcanic soil, as light and dry as ashes, into which the feet of our horses sank to the fetlocks, produces almost nothing but an apparently unending succession of large trees of *P. ponderosa*." Again, in the Pacific Survey, treating of the country between the Cascades and Sierra Nevada and the Rocky Mountains, we read: "The climate is everywhere characterised by the absence of moisture, which, with the exception of the mountain summits that project above the general level, gives to the surface a character to which the name of desert has not been inappropriately applied. The general aspect of the botany of this region is made up of three distinct elements. Of these the first is represented by the grassy plains which border the streams flowing down from the mountains. On these surfaces grow a considerable variety of annual vegetation, in its general character not unlike that of the Sacramento Valley. The second of these botanical phases is that of the sage plains—surfaces upon which little or nothing else than clumps of *Artemisia* will grow. The third is formed by forests of yellow pine (*P. ponderosa*), which apparently finds on these arid surfaces its most congenial habitat. It sometimes happened to us that, during the whole day's ride, we were passing through a continuous forest of these yellow pine trees, in which scarcely a dozen distinct species of plants could be found. The yellow pine, as it grows in these sterile regions, is a noble tree; and, though never rivalling the gigantic sugar pine in its dimensions, it claims among western pines the second place. At McCumber's we saw many of this species six feet and even seven feet in diameter three feet from the ground; and near the base of Mount Jefferson, in Oregon, I saw one which was twenty-five feet in circumference at the same height."

Inhabiting such a vast region of country, and living under such striking varieties of conditions, now in alpine meadows, and now in hot, gravelly plains, as is the case in Mendocino County, California, there is great variety found in the form and size of the tree, and even in the quality of its timber. Professor Bolander informed me that there was a remarkable difference in the size of the cones; those in a dense forest being very small, while those of isolated trees standing in alpine meadows, or on open mountain sides, are from four to six times larger. Everywhere on the Californian mountains it may be seen, and, in fact, usually it is the commonest tree in the mighty forest region running through California and Oregon northward. On the Sierras, it usually grows at elevations of from 1,500 to 9,000 feet, and it attains a height of from one hundred to two hundred and fifty feet.

The port of *P. ponderosa* is somewhat more spreading than *P. Lambertiana*, though far less so than *P. Sabiniiana*. Where the last two species grow together, the contrast in form is very

striking, as is also the colour and character of the foliage. The wood of the yellow pine is generally highly resinous, and, though heavy, is brittle and less valuable than that of the sugar pine. Like the "pitch pine" of the Eastern States, it is, however, sometimes of excellent quality, containing little resin, soft and tough. The yellow pine exhibits a tendency to twist, which is very noticeable in a forest of these trees, the grain of trunk and branches being often seen coiled into the closest possible spiral. The bark of the yellow pine affords one of its most noticeable and distinctive characters. It is light yellowish-brown (cork colour), and is divided into large plates, four, six, or eight inches in breadth, which are flat and smooth, and enable one to distinguish the trunk of this tree at a considerable distance. The plates of cork-like bark are made the repositories of acorns by the woodpeckers, and it is a very common thing to see large numbers of these trees having the bark of the trunk cut into a honeycomb by thickly-set holes as large as thimbles, or as thickly studded with inserted acorns. The colour of the leaves is a dark yellow green, and readily distinguishable from the deep blue-green of *P. Lambertiana*, or the light blue-green, or glaucous hue, of *P. Sabiniiana*. The successive appearance and decadence of clusters of leaves at the ends of the branches, give to the smaller ones a beaded character, which distinguishes it from all other western pines. The smaller branches, and especially the central shoot in young trees, are strongly marked with the scales of the fallen leaves, closely resembling in some cases the leaf scars of the lepidodendron fossils of the coal period. The cones of *P. ponderosa* are from three to six inches in length, ovoid in form, the bosses of the scales bearing small acute recurved spines. The cones grow singly or in clusters of from two to four, generally at the extremities of the smaller branches, and are not pendent, as in the group of pines to which *P. Lambertiana* and *P. strobus* belong. The seeds are somewhat larger than apple seeds, and form the principal subsistence of several kinds of birds.

In England the young trees are of rapid and robust growth, quite hardy, and of noble aspect; the branches are few, in regular whorls, horizontally placed, robust and more or less flexed, with the lower ones inclined to assume a somewhat drooping habit as the tree becomes old. The lateral branchlets are somewhat slender, more or less drooping, and growing in various directions; while the top or leading shoot is often more than an inch in diameter, and of very considerable length. The buds, bluntly domed, with a prominent point and full of resin; the leaves are thickly set on the branches in threes, from eight to ten inches long, rather broad and straight, but twisted at the base, with persistent sheaths one inch long and smooth when young, but much shorter and shrivelled on the older ones. This kind of pine is very subject in England to be attacked by the small pine beetle (*Hylurgus*), which destroys the young shoots by boring in their centres.

We shall be glad of information as to the progress this tree is making in various parts of the country. The following are the names of the places to which Douglas's plants were sent:—Dropmore, Chatsworth, Elvaston, Carlewood, Woburn, Bayfordbury, Bicton, Croome, Trentham, Belsay, Flitwich, Bear Wood, Boyton, Redleaf, Chipstead, Beauport, Carlton Hall, Haddo House, and Hopetoun House.

Our engraving, by Mr. Whymper, is from a noble photograph brought from San Francisco by the Conductor, and taken in the Yosemite Valley by Mr. Watkins.

GEORGE GORDON, A.L.S.

Planting Trees.—After all, the most encouraging things I find in the treatise *De Seuectis* are the stories of men who have found new occupations when growing old, or kept up their common pursuits in the extreme period of life. Cato learned Greek when he was old, and speaks of wishing to learn the fiddle or some such instrument (*fiddle*), after the example of Socrates. Solon learned something new in his old age, as he gloried to proclaim. Cyrus pointed out his pride and pleasure in the trees he had planted in his own lands. I remember a pillar on the Duke of Argyll's plantation at Alnwick with an inscription in similar words, if not the same. That like other country pleasures, never wears out. None is too rich, none too poor, none too young, none too old, to enjoy it. There is a New England story I have heard more to the point, however, than any of Cicero's. A young farmer was urged to set out some apple-trees. "No," said he, "they are too long growing, and I don't want to plant for other people." "But your farm," said the speaker, "was split up among your sons, and the apple-trees were alone, and life was fleeting." At last some one mentioned it to the old grandfather of the young farmer. He had nothing else to do, so he stuck in some trees. He lived long enough to drink barrels of cider made from the apples that grew on those trees.

NOTES AND QUESTIONS ON FRUIT-GARDENING.

Cherries.—It would be very interesting if we could settle the question whether lime in the soil is good or bad for cherries. I have come to the conclusion that it is injurious. Some years since, Mr. Rivers recommended chalk for stone fruit, and I procured a truck-load from Ipswich to experiment with. A small proportion of chalk was added to the soil, in which a number of cherries was potted, consisting of a large number of varieties, and almost every tree became unhealthy. Whilst the question as to the cause was occupying my mind, I happened to drive through a part of Derbyshire, near Dale Abbey, and remarked some of the finest cherry-trees I ever saw, loaded with very large crops; indeed, the trees at a distance showed quite red with the enormous crop of ripe fruit. The land is on the millstone grit, and the soil must be almost destitute of lime in every shape, because the foxglove and bracken (*Pteris aquilina*) are everywhere common. What I want to discover is whether cherries are known to flourish on a soil containing much chalk or lime. It is not enough to know that lime is or is not present in the formation in which, or rather above which, cherries flourish and attain a great size, but whether the surface soil contains lime or not. I have known an oolite soil almost destitute of lime for several feet, and turnips unhealthy in consequence; and it is well known some so-called chalk soils are benefitted by dressings of chalk.—J. R. PEARSON (Chilwell).

Pears grafted on Apple Stocks.—Is it true, as is asserted and reiterated every day, that pears cannot be grafted on apples with any chance of success? Have any important experiments been made recently to settle this question? Experiments have been limited to the grafting of only a few kinds, and, from the results of these, absolute consequences have been inferred for all cases. We do not question the truth of the failures; what we deplore is that from these failures too general and sweeping conclusions have been drawn. We have at the Museum two specimens which support us in our condemnation of the exclusive character of the rule. One is a specimen of *Bartlett de Melaine*, which is in this experiment covered with very small fruit; the other is a *Doucer Spresso* or *Fondante des Bois*, which, this year, is also loaded with splendid fruit. These trees, which are handsome and vigorous, and the very clean bark of which shows a perfect condition of health, were grafted on the *Doucine* in 1856. This was not done by accident, but from our desire to prove the truth of the asserted incompatibility of the organism of the two trees, and we mention it here only to urge that experiments should be made on a larger scale, and in different conditions, so we cannot too often repeat that generalisation should be avoided, and also that we should only form our opinions from facts, especially in matters of horticulture, since experiments which fail in one place sometimes succeed in another. The following is our notion of what should be done.—Take fifty varieties of pears, and graft two of each kind by shield-budding, and two more by cleft-grafting. We recommend the two methods to be tried, as there are cases in which these two operations are followed by entirely different results. This may appear singular, but so it is.—M. CARRIERE, in *Recueil Horticultural*.

The Author of "Waverley" on Planting Fruit-Trees.—Reading the other day for the first time Sir Walter Scott's "Antiquary," I was struck with a passage at the commencement of the fourth chapter, in which Mr. Oldbuck points out to Lovel the method of planting fruit-trees adopted by the monks of old, and which plainly shows that the idea therein manifested, so far from being modern, is almost as "old as the hills." Two friends moved through a little orchard where they agreed upon a walk, left without fruit showed, as is usual with the neighbourhood of monastic buildings, that the old trees had not always been in indolence, but often were devoted to their gardens. Mr. Oldbuck failed not to make Lovel take notice that the planters of those days were possessed of the "modern" secret of preventing the roots of fruit-trees from penetrating the subsoil, and compelling them to spread in a lateral direction by placing paving-stones beneath when first planted, so as to interpose a barrier in his day. We have had plenty of writers who have also claimed it as a modern one in our day.—A. D.

THE INDOOR-GARDEN.

THE ODOURS OF ORCHIDS.

Some years since, M. Rivière, head-gardener at the Luxembourg in Paris, commenced some observations on the odours of the orchids under his care, with respect to which he communicated new and interesting, but unfortunately few, facts to the Horticultural Society of Paris. He was kind enough, sometime afterwards, to supplement this communication by a letter to myself in July, 1866, which contained many singular remarks. Amongst these he mentioned the circumstance that *Cattleya bulbosa* (or *C. Walkeriana*) emits an odour of vanilla in the daytime and the scent of an iris at night. He required further experiment, however, to verify this statement. Since that time I have received no communication from him on the subject; but from my own investigations I have learnt that nothing is more common than to meet with similar phenomena in many exotic orchids. The following notes are the first-fruits of the experiments which I am now making, the further results of which shall be published in due course. They refer exclusively to winter-flowering kinds, which I have studied from January to the beginning of March:—

Aerides Fimbriata: a sweet odour of panies in the evening, and the same in the morning, with a sharp after-flavour.

Angraecum eburneum: a sweet and faint odour, undefinable in the morning, but decidedly like that of violets in the evening.

Cattleya bogotensis: an odour of gilliflower in the morning, and of primroses in the evening.

Cattleya Choerocarpa (new species): a sharpish odour of Reine Claude plums in the morning.

Cattleya Eldorado: an odour of roses in the evening only.

Cattleya elegans: a faint odour of tuberos in the morning, and a strong one of gardenia in the evening.

Cattleya quadrangularis: a sweet odour of vanilla, in the morning.

Cyperus rotundus: a sweet odour of violets, and in the morning the exhalation is scentless, with the exception of *C. Schleini*, which in the evening exhales an odour of violets, and in the morning the scent of primroses.

Dendrobium densiflorum: a very faint, irregularly intermittent perfume, sometimes scarcely perceptible.

Dendrobium glaucom: odour of lilac in the evening, and of heliotrope in the morning.

Dendrobium nobile: odour of grass in the evening, of honey at noon, and a faint primrose scent in the morning.

Epidendrum enatum: an odour of carnations in the morning; scentless in the evening.

Lelia acuminata: a sweet primrose scent, in the morning.

Lycaste grandiflora: an odour of newly threshed corn, in the morning.

Lycomyrmex: a sweet odour of violets.

Malaxis triangularis: a very decided odour of melons, in the morning.

Odontoglossum cupulatum integrum: a faint odour of lilac, in the morning only.

Odontoglossum cristatum: a faint odour of spiraea, in the evening.

Odontoglossum Lindleyanum: a gontish smell, in the morning only.

Odontoglossum neudeckeri: an odour of *catt. siccere* mixed with orange-blossom in the morning, and a faint trace of spiraea in the evening.

Odontoglossum pulchellum: a sweet odour of vanilla, in the morning.

Odontoglossum triplinervium: varies much according to the varieties of the plants.

Some are quite scentless, especially in the evening; others have an odour of panies, but most frequently emit a more or less strong scent of cimicifuga.

Oncidium cucullatum: a sweet odour of violets, in the morning.

Ocimum leptocephalum: a faint perfume in the morning, and a very sweet odour of vanilla in the evening.

Oncidium oblongum: an odour of lilac in the morning, and of elder-flowers in the evening.

Phalaenopsis Schilleriana: a delicate perfume of roses in the evening, and a stronger one of lily-of-the-valley in the morning.

Piliunum fragrans: an odour of vanilla in the morning, and of narcissus in the evening. It varies much in sweetness, and is sometimes scentless, according as the plant has been brought from Peru or from the Sierra Nevada of New Granada.

Schomburgkia glauca: a faint odour of solanum, in the evening only.

Vanda parviflora: an odour of iris in the evening, and of perfumed leather in the morning.

Vanda mormo: a constant perfume of gillyflowers.

Vanda tricolor: odour of gillyflower, much stronger in the morning than in the evening.

By the term "morning" I mean from 6 to 8 o'clock A.M., and by "evening" from 6 to 7 o'clock P.M. My observations have been conducted during fine, bright, sunshiny winter weather, and in places where the temperature ranged from a minimum of 45 deg. to 50 deg., to a maximum of 65 deg. to 75 deg. Fahr. I would recommend those who are desirous of making experiments in this direction to take into account the condition of the atmosphere and weather at the time of making their experiments, and to note the difference in the results of observations made in different localities. Amongst these singular facts, which it would be at present premature to attempt to classify or explain, I may mention that all the Cattleyas exhale very different odours, and that these plants (the species of which are few, but the varieties innumerable) present almost as great a diversity in the perfumes as they do in the colours of their flowers. *Vanda gigantea* also exhibits a striking coincidence in its thick leathery flowers and the smell of leather which they emit. Lastly, the intermittent odours, the exhalation of which cannot be explained as the result of the application of greater heat, or of any other apparent cause, inasmuch as the times at which they manifest themselves are very variable and uncertain, afford ample matter for reflection and interesting investigation.

ED. ANDRE.

Grifflinia Blumenhavia.—This is the best of the stove bulbous plants from tropical America yet introduced; producing a graceful head of rose-striped, pendent flowers of surpassing beauty. The leaves, which are of a drooping character, are about a foot in height, and of a dark glossy green. Being a winter flowering-plant it is of great value at that season in a decorative point of view. The best soil for it is turf loam, intermixed with a little sand. Experience has proved to me that none of these bulbs like manure; and when the drainage is good they are best kept growing all the year round, as they are apt if allowed rest to start afresh badly. The best situation for them is as near the light as possible, with a moist atmosphere. Six bulbs in a six-inch pot make a good clump. If permitted to go to rest they should be started in bottom heat, which is required more to maintain a regular amount of moisture than for the sake of the heat. This particular species was introduced to our gardens some four years ago, and well deserves to have a place in every stove.—J.C.

In the culture of flowers there cannot, by their very nature, be anything solitary or exclusive. The wind that sweeps over the cottage porch, sweeps over the garden; and the pleasure equal to the mind descends over the just and the unjust, so it communicates to all gardeners, both rich and poor, an interchange of pleasure and enjoyment; and the gardener and the rich man, in developing or enhancing a fruitful flavour or a delightful scent is in some sort the gardener of everybody else.—CHARLES DICKENS.

"Water Sparingly."—How often is this advice given as autumn approaches, and how often too, is it severely practised by many! I say, never water sparingly; when you water, water thoroughly. Do not be persuaded that by withholding water from the roots of a plant you thereby hasten its maturity, you may force it to shed its leaves; but, on examination, you will find its buds green, its bark shrivelled, and its roots far from being in a healthy condition. We may be told we must hasten the ripening process, in order to give time for rest, I would rather give shorter time for this so-called rest; it is of very little consequence compared with the proper ripening of the buds and roots. The best helps for ripening with which I am acquainted are heat, light, and air, with a comparatively, but not too, dry atmosphere. A great deal can be done by the removal of superfluous immature shoots, so as to admit light to every leaf that is left, and by withholding stimulants early, but never by withholding water from the roots. How much fuel is wasted in winter, and how many disappointments are caused through trying to force into growth apparently ripened fruit-trees; how puny the shoots are when they do appear, after weeks of hard firing; the flowers, too, are weak and imperfect; they are then said to set badly, the fact being that there has been but little to set, simply because when the tree had its most important function to perform, viz., perfecting its flower-buds, it was checked by having its supply of water limited.

Longleaf.

W.M. TAYLOR.

ANTHURIUM SCHERZERIANUM.

This is one of the most brilliant and valuable stove-plants ever introduced. The singular form and intense although not gaudy colour of its flowers, accompanied by gracefully-curved foliage, and lasting, as they do, in good condition for eight or ten weeks, render it a most valuable plant. It is found in Guatemala and Costa Rica, probably in the hill district, as I find it does much better with cooler treatment than it is often subjected. With me the plant is never quite at rest; it is kept in a house, the night temperature of which, from the beginning of November to the end of February, runs from 50 deg. to 55 deg., with a rise of 6 deg. or 8 deg. by day, during which season it receives less water than in the more active period of growth, when the night temperature averages from 60 deg. to 65 deg., and 70 deg. to 75 deg. by day, with a copious supply of water overhead and at the roots. This latter at once points to the necessity of a porous material to grow it in, as well as ample drainage. I use two parts best fibrous peat, such as orchids delight in, broken about the size of pigeons' eggs, with all earthy particles sifted out, to one part clean sphagnum, with a liberal admixture of broken crocks and silver sand; potting quite loosely, the whole material in a condition

Specimen of *Anthurium Scherzerianum* (1 foot in diameter).

to let the water run through it like a sieve. Its roots cling to the side of the pot like an orchid, hence the necessity of using material that will not often require renewing; as, however carefully the operation of potting is performed, the roots get a good deal mutilated. In re-potting, I break the pot with a hammer all round and get the pieces as carefully off as I can; then I take a bucket of tepid water, in which I gently move the ball until all soil is washed out; many of the crocks being held as firmly by the roots as if it were an orchid.

Those are not disturbed. I then take a pot four or six inches larger than the one previously used, half filled with drainage, in which I place the plant well up in the centre of the pot, and gradually work the new soil amongst the roots without pressing it so as to injure them, and then give a little water. But for about a month afterwards I am careful not to give too much, until any roots that have been injured have had time to heal. Its principal enemies are brown scale and thrips; the former seems thoroughly at home upon it, and thrives amazingly. The thrips get in the spathes as soon as they begin to open, and disfigure the flowers, if not dislodged. I use the sponge diligently for the scale, and the syringe for the thrips, as soon as the flowers begin to open, which, from their strong leathery texture and the natural liking the plant has for water, does not injure them in the least. Always keep the plant slightly shaded in bright weather. There are several forms of this plant, more or less attractive. Therefore it behoves those who purchase plants to make sure they obtain the right one, which is much larger in its leaves and flowers, and more intense in colour than the others. The inferior forms and small plants often convey a very imperfect idea of what the plant really is, as compared with a large well-grown specimen of the best variety, although the larger variety does not yield near so many flowers at any one time as the smaller one. A plant we have here, of the best variety, is now four feet through, and when exhibited in May last at the Crystal Palace it had on it twenty-four perfect flowers, the foot stalks of which were two feet long, and some of the spathes measured 5½ inches long by 3½ inches broad.

Southgate.

T. BAINES.

THE LARGE-LEAVED BERBERISES FOR THE CONSERVATORY.

The chief improvement required in all our large conservatories is the planting out of various plants of noble port which will furnish the structure with refreshing verdure and stately forms at all seasons. Thus arranged, immeasurably better effect may be produced than at present when the conservatory so often depends entirely on the plant-houses. A few dozen handsome flowering-plants here and there in such a house would furnish a lovelier effect than could be obtained by any means on the older and too common principle. But everything depends on the judicious selection of the plants to be thus permanently planted. If subjects are used which, like some of the acacias, will quickly run up to the roof, then good bye to all good effect. Hardy

Berberis nepalensis (grown in cool conservatory).

palms, hardy tree and other forms, and *Dracanas*, &c., are the sort of plants we should seek. The New Zealand flax, too, and its varieties and allied forms, always low yet always stately, I have also noticed producing a capital effect on the Continent in conservatories. But no plants are more suitable for planting out in the borders of the conservatory or winter-garden than the noble large-leaved berberises,

of which the accompanying figure represents *B. nepalensis*. These remarkable plants, so often seen in a starved and dwindled condition about London and in various parts of the country, find in a cool house of any kind the very conditions they delight in, and whosoever will plant them therein will soon be rewarded with as' noble foliage, as rich crests of bloom, and as stately a port, as we can find combined in any plant. In districts where these fine plants do well in the open air, it would not be so wise to use them in the conservatory, but in the numerous places where the berberises, going by the name of *B. Bealii*, *nepalensis*, *japonica*, &c., are sickly dwarf shrubs, they may, with the greatest advantage, be employed in the conservatory.

The Drynarias.—The excellent plan of planting out exotic ferns on picturesque banks, &c., to the hothouse is becoming more popular every day; when well done, its effect is of the most satisfactory kind. The arrangements should not as a rule be confined to ferns. Noble Arums, such as may be seen in the Arum house at Kew, and the singlo *Monstera*, add greatly to the charms of the

ferns. But where ferns alone are used, much improvement may be effected by selecting distinct and noble types to contrast with the large and small ferns in cultivation. Among the nobler kinds of stemless ferns we know nothing more worthy of attention than the *Drynarias*, forming as they do such huge leaves and noble nest-like crests. For rocky or elevated points the species figured (*D. morbillosa*) and *D. coronans* are superb.

Cordyline indivisa.—This is perhaps the noblest of all the greenhouse *Dracaena* tribe, especially when well grown, its long and golden-striped leaves having a peculiarly rich and unusual appearance.

It is a native of New Zealand, and consequently requires cool greenhouse treatment; but many cultivators, in their haste to get

large plants, subject it to stove treatment, and then, no matter how fast it may grow, it will die off much faster—and that without any apparent cause; no sooner is it subjected to cool treatment, and gets an extra supply of cold water, than it perishes. The best treatment is the following: Procure a nice healthy plant in a four-inch pot early in spring, and, if the roots are fresh and healthy, remove it at once into an eight-inch pot; but if they are not strong, then a six-inch pot will be sufficient for the first shift. The most suitable compost is fibrous peat and loam in equal proportions, broken so as to pass through the meshes of a half-inch sieve, but with the fine portions sifted out. To the rough pieces add an eighth of potsherds and charcoal, broken to the size of peas, and sufficient sand to make the whole perfectly porous. Let the pots be perfectly clean, and drain them thoroughly. In potting, take care to keep the base or collar of the plant well rounded up, and press the soil as firmly as if you were potting a heath or capraris. Place the plant in a warm and shaded part of the greenhouse, and water cautiously until such time as the plant starts into free growth, and then a copious supply may be given. If the plant gets into free growth, a second and perhaps third shift may be given during the season; but it will not be advisable to shift later than the end of July, as it is important that the pot should be full of roots before the winter commences. As the light decreases, gradually diminish the supply of water, so that the plant may be kept comparatively dry during the winter. The best situation for the plant through the winter will be a dry shelf, where there is a free circulation of air, but no cold draughts. In such a situation, with judicious attention, the *Cordyline* will grow on for years.—A.

NATURE'S GARDENS.

NIAGARA.

THE earth is indeed one vast garden with great drought-parched patches and snow-robed regions here and there, but there are some scenes in which the various elements are so boldly or pleasingly combined that it seems as if Nature herself had planted her a garden. The noblest of Nature's gardens I have yet seen is that of the surroundings and the neighbourhood of the falls of Niagara; before seeing it, I did not think

Bird's-eye view of Islands above the Falls of Niagara

of Niagara as anything but a huge waterfall. Grand as are the colossal falls, the rapids and the course of the river for a considerable distance above and below possess more interest and beauty. Accounts of the noise of the falls are much exaggerated; their sublime beauty no pen can describe.

As the river courses far below the falls, confined between vast walls of rock, the clear water of a peculiar light-greenish hue, and white here and there with circlets of yet unsoothed foam, the effect is startlingly beautiful quite apart from the falls. The high cliffs are crested with woods; the ruins of the great rock-walls, forming wide irregular banks between them and the water, are also beautifully clothed with wood to the river's edge, often so far below that you sometimes look from the upper brink down on the top of tall pines that seem diminished in size. The wild vines scramble among the trees, many shrubs and flowers seam the high rocks; in moist spots here and there a sharp eye may detect many-flowered tufts of the beautiful fringed gentian, strange to European eyes, and beyond all, and at the upper end of the wood-embowered deep river-bed, a portion of the crowning glory of the scene—the

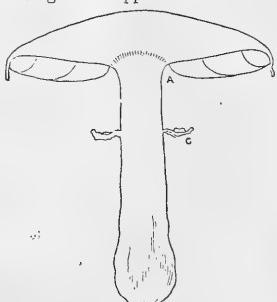

falls—a vast cliff of illuminated foam, with a zone towards its upper edge as of green molten glass. Above the falls the scene is quite different, a wide and peaceful river carrying the surplus waters of an inland sea, till it gradually finds itself in the coils of the rapids, and is soon lashed into such a turmoil as we might expect if a dozen unpolluted Shannons or Seines were running a race together. A river no more, but a sea unreined. By walking about a mile above the falls on the Canadian shore this effect is finely seen, the breadth of the river helping a poor Britisher (whose rivers are "creeks," if he only knew it) to carry out the illusion. As the great waste of waters descends from its dark grey and smooth bed and falls whitening into foam, it seems as if tide after tide were gale-heaped one on another on a sea strand. The islands just above the falls enable one to stand in the midst of these rapids where they rush by lashed into passionate haste; now boiling over some hidden swellings in the rocky bed, or dashing over greater but yet hidden obstructions with such force that the crest of the uplifted mass is dashed about as freely as a white charger's mane; now darkly falling into a cavity several yards below the level of the surrounding water, and, when unobstructed, surging by in countless eddies to the mist-crested falls below so rapidly that the drift wood dashes on swift as swallow on the wing. Undisturbed in their peaceful shadiness, garlanded with wild vine and wild flowers, the islands stand in the midst of all this fierce commotion of waters—below, the vast ever-mining falls; above, a complication of torrents that seem fitted to wear away iron shores, there they stand, safe as if the spirit of beauty had in mercy exempted them from decay. Several islets are so small that it is really remarkable how they support vegetation, and one bold-looking thing, no bigger than a washing tub, not only holds its own in the very thick of the currents just above the falls, but actually bears a small forest, including one stricken and half cast-down pine. It looks a home for Gulliver in Brobdingnagian scenery. Most fortunate is it that these beautifully verdant islands and islets occur just above the falls, adding immeasurably to the effect of the scene. Magnificent it would have been without them, but their presence makes Nature seem as fair as terrible in her strength.

To be continued.

THE HOUSEHOLD.

THE TRUE MUSHROOM.

The question is frequently asked, are there any infallible rules for distinguishing the true mushroom from all other fungi? and, if so, what are the crucial points of distinction? First, and foremost, the true mushroom (*Agaricus campestris*) is invariably found amongst grass in rich open pastures, and never on or about stumps, or in woods. Many cases of poisoning have occurred owing to the supposed mushrooms being gathered

Section of the true Mushroom.

from stumps or in woods; it is true there is a certain variety found in woods and woody places (*A. silicola*); but, as far as amateurs are concerned, it is best left alone. A second very good point is the peculiar, intense purple-brown colour of the spores (which are analogous to seeds); the ripe, and fully-

mature mushroom, derives the intense purple-brown colour (almost black) of its gills, from the presence of these innumerable coloured spores. To see these spores, and so become acquainted with the peculiar colour, remove the stem from a mushroom, and lay the upper portion, with the gills lowermost, on a sheet of writing-paper; in a few hours the spores will be deposited in a thick, dark, impalpable powder. Several dangerous species, at times mistaken for this mushroom, have these spores umber-brown, or pale umber-brown, in colour, and belong to *Pholiota* or *Hebeloma*. In the accompanying figure is shown a vertical section of the true mushroom, which differs (when the colour of the spores is taken into consideration) from almost all other agarics, and certainly from all poisonous ones. One of the principal points to be observed is the distinct and perfect collar at *C*, quite encircling the stem, and the edge of cap at *B*, overlapping the gills; in some poisonous allies, as *A. arvensis* (generally found on and about stumps), this ring is reduced to a mere fringe, and the overlapping margin is absent, or reduced to a few mere white flecks or scales. Lastly, the gills never reach or touch the stem *A*, for, on inverting a mushroom, a blank space will be seen all round the top of the stem where the gills are free from the stalk. There are innumerable varieties of the true mushroom (and of the horse-mushroom), but all are equally good for the table; sometimes the top is white and soft, like kid-leather; at other times it is dark-brown and scaly. Sometimes, on being cut or broken, the mushroom changes colour to yellow, or even blood-red; at other times no change whatever takes place. But, observe, the mushroom always grows in pastures; always has dark purple-brown spores; always has a perfect encircling cloth-like collar; and always gills which do not touch the stem, and a top with an overlapping edge.

W. G. S.

THE TOMATO.

In Europe the tomato is occasionally used; in America it is as indispensable as bread. From the hot States round the Gulf, and from sunny and genial California, where it grows as freely as groundsel does in England, to the Canadas and the Northern States, where it must first be raised in heat, as with us, the tomato is a blessing to the country. No other product is so popular with all classes, high and low, and probably none so wholesome among the many things there used. For months, in summer and autumn, it may be gathered fresh. It shares the fate of peaches, pears, and oysters, and is preserved in tins for winter use, so that practically it is obtainable all the year round. Stewed, baked, as sauce, or in soup, eaten raw as a salad, or with sugar, in all these ways it is good. It would be worth while crossing the Atlantic for the sake of a tomato-salad, if one could not enjoy that luxury in England. In every country enjoying a higher temperature than that of England, the tomato should be grown abundantly as a common garden or field crop; and even where, as in northern England, you cannot even ripen tomatoes against walls, they may be easily grown in empty frames, &c., unused in summer; and, once plentiful, every child would learn to relish a food so wholesome and so excellent. It is scarcely necessary to point out the vast extent of territory in the colonies of England in which the tomato may be grown as well, and found as useful and important an article of food, as in the most favoured parts of America. There can be little doubt that Americans have much for which to thank the tomato. Such quantities of unwholesome and indigestible matter, in the shape of sweet cakes and sweets of all kinds, condiments, &c., are eaten there, that one might suppose it indispensable to resort to simple, healthful food by way of corrective; and the tomato saves society from the effects of a miserably unwholesome system of gastronomy.

Philanthropic travellers would do well to scatter a few tomato-seeds on their way through hot and temperate desert countries, for, in the absence of kitchen and cook, few things would be more acceptable to the hungry wanderer. Away from towns in Canada or the States—in places, it may be, many miles from a town, where fresh meat is rarely seen, and cookery, of the few things to be had, an abomination—a wholesome meal may be made from a plate of tomatoes, gathered in the garden, and a piece of bread.

Little need be said on the culture of the tomato. In the States and Canada West tomatoes bear till they are literally borne down with weight of fruit, each plant producing about twice as much as it would against a wall in the south of England. In all parts of the West they are even finer: in California, they do splendidly also, both on plain and hill; and also in arid-looking Utah. I remember noticing one plant in Brigham Young's garden, at Salt Lake City, which spread over the ground almost as far as a gourd plant would with us. So will they thrive in all countries with a warm summer. No plant

returns a more abundant yield with so little trouble. It is a curious fact that to relish some undeniably good things not a few people require nearly as much education as suffices to change a Conservative into an active Reformer. Some persons affect a dislike to tomatoes, but such have never given them a fair trial. They will not impart all their virtues at once, especially to doubtful and sneering novices. In a raw state they may at first fail to charm, but never if properly cooked; and cooking them is such a very simple affair! Yet, in a country like England, where they are not by any means common, persons will be slow to recognise their merit.

The above is Mr. Robinson's account of the tomato in America. The following recipes may serve to make the uses of this invaluable plant better known among ourselves:—

TOMATOES AT PLATE.—Butter a warmed metal or earthenware plate that will stand the fire and add pepper and salt, and cut, in the flat direction, as many tomatoes as you please, and place them in the butter; season, and cover with a lid. When cold, turn them out, and place them in a dish over a fire, lightly fried and served with the same sauce, are strongly to be recommended.

TOMATO CHUTNEY.—Take 4 lb. tomatoes, 2 lbs. onions, 1 lb. apples, 1 oz. salt, capsicums, or cayenne to taste, and one pint of vinegar. Boil two hours, and beat the whole through a colander. When cold put into small bottles, and cork very tightly. The corks are best sealed over to exclude air, and placed away in a cool place. It will keep many months.

TOMATOES AT GLAZER.—Take tomatoes, two inches in diameter, pare off the skin round the stalk, and make an opening one inch in diameter in the tomatoes, to allow of taking out the seeds with the handle of a teaspoon; season with 2 pinches of salt, and 2 small pinches of pepper. Prepare some *fine* stuffing as follows:—Put in a quart stewpan 1 oz. of butter and $\frac{1}{2}$ oz. of flour. Stir over the fire for two minutes; then add 1 pint of broth; stir, till reduced to half the quantity; and add in 3 tablespoonsfuls of chopped and washed parsley, 1 tablespoonful of chopped and well-shaken sandwiches of salt, 1 small pinch of pepper; reduce on a brisk fire for eight minutes.

TOMATO-SAUCE.—This is made either with fresh or preserved tomatoes. Choose a dozen bright-red tomatoes (say 2 lbs.); cut away the stalks; cut each tomato in two; press out the seeds and water; and put them in a two-quart stewpan, with 1 flagon of sweet-herbs, 2 gills of water, 2 pinches of salt, 1 small pinch of pepper. Put the stewpan on the fire, well covered; boil for forty minutes, stirring with a wooden spoon every five minutes, and pressing the tomatoes catching; press through a wire sieve. Make a *roux* in a quart stewpan, with 1 oz. of butter and $\frac{1}{2}$ oz. of flour; stir over the fire for three minutes; remove the stewpan from the fire, and mix the purée of tomatoes by small quantities, stirring well all the time; add 2 gills of broth, and boil again for twenty minutes. If the sauce be too thick, mix one or part of a gill of broth. When preserved tomatoes are used, proceed in the same way, adding the preserved tomatoes, and then adding three of fresh tomatoes; mix with the roux and broth; taste, and serve as before.

TOMATOES AT NATUREL.—During the heat of summer in no way is the tomato more agreeable to those who know its merits than when eaten "from the bush." The process is simple. Select a good ripe fruit, place the lips against its glossy sides, bite a piece clean off without fear, and then suck with all your might. At first certain succulent leathery coats may offer some resistance, but soon the red heart's juice, kept cool in the hottest days by the outer coats, will begin to flow, and victory will be yours.

W. B. TEGETMEIER.

THE COMPASS PLANT.

(*SILPHIUM LACINIATUM.*)

Few amongst hardy plants, are better adapted for association with those tropical forms now so largely cultivated for the purposes of flower-garden decoration than the above-named plant. Those who have the management of even our first-class flower-gardens will be well aware of the value of really hardy, and, at the same time, ornamental-foliaged plants. So treacherous and precarious are our seasons, and so liable is the whole beauty of the more tender plants to be swept away by early frost, that I need make no apology for introducing, as well deserving of notice, a plant that now (the first week in November) looks as fresh and green as at any time during the season.

I will endeavour to describe the plant to which I allude, as briefly as possible. The radical leaves form a cluster about four feet in diameter; they are pinnati-partite, or as the name very appropriately implies, laciniate, with the primary lobes slightly notched, having the appearance, at first sight, of being compound; but as each narrow segment is carried down the mid-rib, thus forming a winged appendage, uniting the whole, they must be considered as simple leaves; their length is from 2½ inches to 3 feet, and in their arrangement they are more usually vertical than horizontal. This irregularity is rather of advantage than otherwise, and, when coupled with the peculiar texture, hard and rigid to the feel, though by no means so in outline, and showing a sort of mosaic of minute divisions between the veinlets, they have somewhat the appearance of large broadly-divided fern fronds. From the centre of this group rises a stout stem to the height of about fourteen feet, with leaves of a similar character, gradually diminishing from the base to the summit, and producing from the axils of those that occur along the upper half, flowers of moderate-size, with long florets of the ray, of a pretty lemon-yellow; these indicate at once its proximity to the *Helianthus*, or sun-flower tribe, to which genus it is pretty closely related.

It will scarcely be necessary, after the foregoing description, to say that it is a plant of vigorous habit, forming enormous roots, which, with us, are deep in the very rankest clay soil. To this fact, possibly, its enormous development, as regards height, is to be attributed; and in sandy soil, even though well manured, it rarely reaches beyond five or six feet.

There is a further interest connected with this plant, in the fact that it is known to the North American Indians as the "Compass plant," and by some peculiarity in the arrangement of the leaves when growing *en masse*, as it does on the wide prairie-lands of the far West, the Indian, with that instinctive power with which semi-civilization is generally endowed, is able, under a clouded sun, to shape his course for his far-off settlement, in a country where landmarks are few and far between.

There are about a dozen other species of *Silphiums* in cultivation, but rarely met with, except in botanical collections; nor have any of them either the peculiar beauty or interest which this species possesses.

It may be said,—Why is it so rarely met with? One reason, perhaps, is because it is not new, having been originally introduced in the latter part of last century; and another is, that, being a late autumnal bloomer, it never matures its seed, and appears shy at giving out offsets from the massive rootstock. I think, however, it is more than possible that it may be increased from cuttings of some of the fleshy secondary roots—at least I purpose trying that mode; and I am led to that inference from the fact that having had occasion to remove a plant of *Silphium terebinthinaceum* last season, I found several shoots sent up from the roots that remained buried in the ground where it originally stood.

To those who possess it, I would say, be wary of removing it, as it does not very readily recover that ordeal. It is, in the fullest sense of the word, a permanent perennial plant.

May I close my remarks by making the inquiry if any of your readers have had any experience of a closely allied genus from California, namely, *Wyethia*? We have three species in cultivation, but they appear very slow growers, which, anomalous as it may appear to some, is to my mind a recommendation.

Botanic Gardens, Hull.

G. C. NIVEN.

THE PROPAGATOR.

Amherstia nobilis.—This is a plant which, though grown and flowered at Ealing Park and elsewhere long since, we nowadays rarely meet with, although its blossoms are so beautiful as even to elicit the praises of poets themselves. Can the difficulty attending its propagation account for its scarcity? If so it may be overcome by cutting the branch half way through, getting a small pot, and, breaking it in half, putting it round the branch, and wiring it; then fill the pot with sandy loam, and in about three months the branch may be cut off and plunged in bottom heat of from 85 deg. to 90 deg., covering with a bell-glass. In India the branch is run through a piece of bamboo filled with soil. The Amherstia does not like soil, but it is fond of water. It is useless to import its seeds, as they do not retain their vitality, however well packed.—J. C.

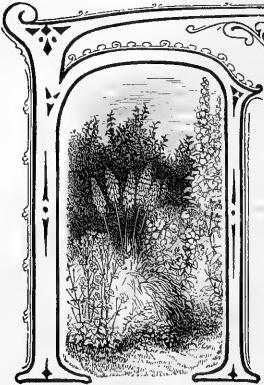

Aralia papyrifera.—This beautiful foliaged plant having become extensively employed in the flower-garden of late, a few hints as to its propagation may be of use. Its stem being nearly all pith does not strike readily; therefore a stock of it cannot be got quickly in that way, but if the root near the stem are examined they will be found to be fleshy. When the plant is taken up, let each of these be cut into pieces about an inch long; insert them in light soil, letting the whole be covered, and place them on a shelf near the glass, in a temperature of 80 deg. Thus circumstanced they will, in due time, throw out shoots, which should be left until they are three inches in length, when they may be potted, leaving them in heat, say, of 70 deg. until established. They should then be removed to a colder temperature, and thence to a frame to harden off. In the south of England this plant is almost hardy, and may be wintered in a cold frame, but it should be kept rather dry.—J. C.

The "Red, White, and Blue."—Few processes are more dispiriting than to go through garden after garden with the same eternal combinations, the same monotonous lines of colour. Instead of giving "three cheers for the red, white, and blue," I always feel a much stronger inclination to emit three dismal howls, heartily wishing these ribbon manufacturers at Coventry—their proper home. What do you think of that, sir?" said a gardener to me in a triumphant tone, as we entered an immense kitchen-garden, ribbed all round with the old familiar pattern. "Well," I made answer, "as nearly as I can calculate, I've seen about sixty miles of it this summer; and, if you don't mind, I will cool my eyes on the parsley."—S. R. HOLE.

GARDEN DESIGN.

HOME LANDSCAPES.

BY NOEL HUMPHREYS.

OME LANDSCAPES are very far from being so common or so beautiful as they are one day likely to be, in consequence of the base taste for the formal and geometrical in gardens lingering so long. Formal gardening was first practised in England about the time of Henry VIII. It was intensified in the formalism of its character during the reigns of Elizabeth and James, and still more so pending the influence of the French taste imported by Charles II.; and under the Dutch influence brought over by William III. it still continued to flourish as vigorously, though in a somewhat modified style.

But in the reign of Anne, symptoms of a more natural taste began to show themselves, as exemplified in the park-like distribution of the land and trees at Blenheim, the noble estate presented to Marlborough as a token of the national appreciation of his great military successes. The laying-out of the ornamental grounds at Blenheim may be considered one of the earliest and most successful attempts at creating scenery of a more natural character round the country residences of our landed aristocracy. The long-avenue feature, and other characteristics of a similar kind, being, as a rule, avoided. The more natural taste thus essayed by "Capability" Brown in park-scenery, can scarcely be said to have been extended to the more confined area of pleasure-gardens near the house, where rectangular walks, cornered by vases or statues, and skirted by trees cropped to simulate green walls or grotesque objects, still lingered as favourite and fundamental features in the formation of our pleasure-gardens; a vicious style, which endured even to the time of Horace Walpole, who, with all his refined taste, did not succeed in understanding those artistic theories which must ever form the true principles of garden art, though he evidently felt a tendency towards better things. But even his galleries of artistic monuments never advanced beyond a superior kind of toy-shops, nor his gardens beyond convenient promenading-grounds for powdered beauties and Cupids and Apollos, and his pretty little squinting fountains.

Nevertheless, the true English love of nature gradually emancipated itself more or less from these trammels, till at last the gardeners of the day thought they had discovered the true system of the picturesque in "serpentine walks" and "undulating turf," with, if possible, the crowning touch of a little piece of winding water, crossed (where it might have been easily jumped) by a "rustic bridge." These features, though but crude in themselves, the more especially when crudely treated, as they most certainly were, nevertheless achieved an easy and rapid victory over straight lines when once put to the test. The new system became extremely popular, not only in England but also on the Continent, where it was imitated under the name of *jardins Anglais*. The *jardin Anglais* of the Petit Trianon at Versailles, and several which were laid out in Russia, under the directions of the all-powerful Potemkin (who for some time forgot the delights of diplomacy and the glories of successful war to indulge his mania for creating English gardens in Russia), may serve as examples.

The simple devices of winding-walks, and curved canals, and rustic bridges, which had fascinated Marie Antoinette and made the great Potemkin forget the cares of State, were, with all their defectiveness, a positive advance, though of a very humble

kind, towards the formation of real garden landscapes upon true principles; and a larger and bolder style very soon began to develop itself, in which far greater breadth of treatment was forced upon the designers of gardens by the growth and beauty of the great Cedars of Lebanon, which Sir Hans Sloane had introduced some years before, and by other new trees which began to display their majestic dimensions and many novel features in their new English home. The utilization of these new features of garden-ornament, necessitated a larger and bolder style of garden art, in so much that the winding-walks and shrub-bounded lawns were extended in scale and improved in character; but, unfortunately, the effective treatment of flowering-plants did not keep pace with that of trees and shrubs. Their value as landscape features was not understood, and the touches of colour produced by them were consequently small and insignificant.

It was attempted, in days still very recent, to remedy this defect by what has been termed the "bedding system," which consists, in principle, in the aggregation of large masses of plants of the same kind in various geometric figures, say, an octagonal mass of two hundred dozen Tom Thumb geraniums as a central object, flanked by two vast diamonds of one hundred dozen each of dwarf blue lobelia, or yellow calceolaria. To these, in convenient situations, were added lengthened borderings of a similar class, called ribbon-borders, formed by continuous lines, four or five deep, say, of purple verbena, faced by a narrow line or edging, two deep, of a white variety of the same plant, and in the extreme front another edging, say, of yellow dwarf *Tropaeolum*. In order to make room for this system to have its full fling, picturesquely shrubbed mounds were levelled down, hollow sweeps filled up, and the shrubs carted away, in order to obtain the clear, open, and level space necessary for the display of the new theory of decorative gardening. And so it was that slopes, clothed with their tufted foliage of various kinds, their Laburnums, Guelder roses, lilacs, and the bright evergreen leaves of laurels and *Laurustinus*, gave place to the low, round pudding of scarlet geraniums, edged round its circumference with two or three strings of plants of strongly contrasting colours; these pudding-strings, as they may be termed, are sometimes composed of plants with richly-coloured leaves, and these effects of coloured foliage are sometimes separated from the central mass of richly-coloured flowers, by an intermediate pudding-string of the white-leaved mouse-ear, or silver moss. Glaring masses of colour of this kind, which in the sun often produce a most dazzling effect of richness, at once took amateur gardeners by storm, and the greenhouses in small establishments were recklessly cleared of the "antiquated" collection of pretty half-hardy plants and shrubs, with their thousand forms of foliage and endless varieties of graceful flowers, to make room for the raising of one thousand dozen sorted bedding plants, to utilize which, after the fashionable manner, the old flowers had to be cleared out of their dear old-fashioned borders, the ancestral tufts of hepatica, that had bloomed there for the delight of successive generations, and grand clumps of towering white lilies, too, had to vacate the spot, where, year after year, they had come up in their glory to be admired. And the noble crown imperials, and the wide patches of double-white *Narcissus*, and the great clumps of the heavy-flowering double daffodils,—

"That take the winds of March with beauty,"
and the grand old peonies, that lolled over the box edgings and seemed so perfectly at home; all these old friends, which year after year had come forth in their beauty, at the accustomed time, on the accustomed spot, to greet their old friends, all had to be routed out. The place, said the cruel, but fashionable, gardener, was wanted for a ribbon-border; and so lilies and hepaticas, and polyanthus and globe flowers, and monkshoods, and all the old-fashioned pets were swept ruthlessly away—*exvent omnes*. The old characters of the garden drama were no longer wanted. *Spectacle* had set in, and gorgeously-attired supernumeraries in astounding numbers crowded the stage in serried masses, each marshalled in form and array upon geometric principles; and thus were numbers substituted for the legitimate characters belonging to the horticultural drama, and the home, so to speak, of poetry was usurped by geometry.

(To be continued.)

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Butcher's Broom with Berries.—Many persons well acquainted with this plant are surprised when told that the female plants bear beautiful scarlet berries, as handsome as any we have. These are rare in gardens in consequence of the prevalence of the male and infertile female plants in our shrubberies and parks. Dr. Lindley has recently obtained a plant of the female species of old one-way tree, berries on butcher's broom's a berry-bearing female plant, and put a male plant alongside. I got my berry-bearer from a garden in Southend, and it has had berries every year since. There is a male plant alongside of it from Dartmouth. Here there are six or seven large pseudo-female plants in the garden, but not one of them ever has a berry on it, though some of them are quite near the fertile female and the male plants. Neither did I ever get berries on the other two specimens from the Royal Park Botanic Garden, which have now five or six seeds of the Southend plant, to see if any females of its descendants are also fruiting.

Aclimatisation of Australian Trees.—Considerable advance has been made of recent years in France in introducing hardy foreign trees and shrubs suitable to the climate; and with a fair amount of success, many natives of warmer climates being found to stand the winters in the southern departments. The *Eucalyptus globulus* has given the best results in the department of the Var, where it has resisted the severity of the continental or northern west wind. It is described as growing with ten times the rapidity of oak trees, and is remarkably well-adapted for the re-clothing of denuded mountains. The improvement that may be thus effected in many dry, warm, and barren parts of America, as along some of the more arid and treelss parts of the Pacific slope, it is impossible to exaggerate. And it is pleasant to reflect that the lovely eucalypti of New Holland, and the gum-trees, unrivaled for their grace of habit, when starting up into the sky at the rate of sixteen feet or so a year, are one day destined to embellish many a region besides their own. We should be glad to learn how the *Eucalypti* are doing in the south of England. With us, however, their employment must be very limited.

THE FRUIT-GARDEN.

IMPROVEMENT IN ORCHARD CULTURE.

THERE is one way by which great improvement in fruit culture may be effected at once and to everybody's satisfaction. I mean by the judicious thinning of the branchlets of standard orchard and garden trees. The natural tendency of trees of the apple order, to which most of our fruits belong, from the hawthorn of our hedges to the snowy-flowered Chinese pear, is to produce a dense profusion of bloom, and consequently of fruit. Sheets of white or pink blossoms in spring, and showers of pretty fruit in autumn, usually adorn them. And the tendency is as apparent in the newest and largest apple and pear as in one of those American thorns laden with crowds of bright scarlet haws. For ages and ages man has bred our hardy fruits, until they so vary in flavour and size and beauty of colour that they puzzle system, and until some of the varieties have no more likeness to the aboriginal native than a Life Guardsman has to a chimpanzee. Yet in one point they still inherit their marked native trait—profuseness in bud and Fruit. It is true that by selection the fruits have become so large that the improvement to be had by judicious thinning is not likely to present itself to many cultivators; but one trial of the system will convert the most obtuse. Nature's tendency is to the production of myriads of individuals, whereas in the case of our fruits we require size and perfection of the individual rather than mere quantity. Let it be duly considered that the total weight of finely developed fruits may equal, or nearly equal, an unthinned and half starved crop, and perhaps be worth three or four times more in money value.

Generally the practice is to leave the crop as much to nature as regards thinning of the branchlets as we do that of the ash or blackberry. One year the tree bears a great crop of fruit, and the whole of its vigour is so drawn up by the many hungry feeders that little remains to form fruit spurs for the following year, and such as are formed may lack vigour to set. Then comes a year of effort in the production of wood and spurs, and perhaps by the end of autumn there will be a score, or even two score, fruit buds on one fruit spur, where one, two, or at most three, would be sufficient. Now, if all be allowed to set, the result will be a dense crop of poor fruit, which, if submitted in the market test, will prove of little value. But if these spurs be thinned so as to force the energies of the tree to be concentrated in fine and succulent fruit, there will also rest sufficient strength in it to form at the same time a medium crop of fruit-buds likely to afford a crop the following year, and to induce a more regularly fertile habit in the tree. By following this thinning system we may, in fact, get good and valuable crops every year; and by the other the alternate and useless profusion before alluded to. The pear requires this attention as much as the apple when grown as a standard or freely developed tree; but, in consequence of being much more grown in a dwarf and contracted form, on espaliers, walls, &c.,

and much pruned, the want of thinning is not so often seen as in the case of the apple.

No method of pruning or training these trees in the open air is better than the freely developed standard tree, if the thinning process be well carried out. And how shall we best do it? Clearly the right way is to thin the branchlets, and the best time in early winter, when it may be done with some comfort and facility, though, of course, at any time through the winter will do. The tree should be opened up in the usual way as regards its main branches, but the chief attention should be given to the regular and bold thinning of the fruit-bearing branchlets, and even to the thinning of the spurs, where there is plenty of time to do so. It may more fully show the importance of this subject when we say that we know of one large orchard plantation of pears to the west of London the fruit of which has brought more than double the amount of money during the last few years, and since falling into the hands of a market gardener who carefully prunes and thins out his trees, than it did when left to nature. The thinning of the branchlets here advised should not be performed till they have begun to bear fruit-buds in too great abundance.

PRUNING AND NAILING IN THE COLD.

THERE are many inhumanities practised in gardening, chiefly, I believe, for want of thought and for lack of sympathy. Masters give orders irrespective of the weather and without regard to the feelings of those who have to execute them. St. Clare remarked concerning his negroes, "How can I punish them for doing exactly what I should have done myself, in their circumstances?" The carrying out of the whole spirit of this remark would prevent much suffering and loss in many gardens. Before ordering others to do certain work, let the question be put,—Should we like to do it ourselves? or, could we do it well under the conditions of heat or cold, wind, rain, frost, &c., then prevailing? Here is a case in point, seasonable and, unfortunately, only too prevalent—that of winter pruning and nailing. There are gardens not a few in which these operations go on, without intermission, in all weathers, unless interrupted by blinding snow or very heavy rain indeed. We have stood on walls—hands and muscles blue—helplessly trying to nail, with fifteen or twenty degrees of frost; or the east wind making a clean sweep through our scanty clothing; or the thick fog, or drizzling rain, as near the freezing-point as rain could fall, slowly, like a terrible fate, drenching us through. No one can estimate the mischief and misery caused by such cruelty. The seeds of diseases unknown—consumption, rheumatism—are sown broadcast among men and boys under such circumstances; and the terrible results are reaped after many days in early graves, and lives of misery and helpless suffering. How many gardeners are the victims of rheumatic and other chronic diseases! We believe that most of them were contracted by an exposure, as inclement and cruel as it was wasteful—for it cannot be too often repeated that no work could be purchased so dear as that of nailing trees in cold weather. No man can do an honest day's work under such conditions. His numbed fingers and his depressed spirits alike forbid it. On the contrary, the man who knows that his comfort has been studied in the matter, will do more training in an hour in genial weather at noon than he could have done in the eight or nine hours of a cold wintry day. Thus, self-interest counsels the aid of humane management: and, indeed, where there is a will in this matter there is no difficulty in finding a way. True, much training must needs be done between November and February, but, by picking opportunities, time will be found for it all. No mild weather should be lost. Every genial day as much as possible should be given up to such occupations; and hours should be picked out as well as days. Work should rise, as it were, in couples in its winter season. A man's job for the morning or evening should be coupled to a cool one, such as training, for the middle of the day. Again, on days when training is practicable, though somewhat cold, it is easy to have a piece of digging or trenching at hand for the men to warm themselves at when they get chilly. More nailing or tying will then be got through than had the processes proceeded without intermission, and the comfort and health of the operatives, as well as the ground tilled, will be so much to the credit of humane management.

It is ever thus that kindness, like virtue, is its own reward. Consideration for the comfort of men is an employer's most profitable investment. Doubtless it will occasionally be abused; but such will not be its fate generally. Like begets like: thoughtfulness for workers, for the interests of masters; and no master was ever any worse, but better, served for embodying in his management the golden rule which succinctly sums up the whole matter of humane management: "Whatsoever ye would that men should do unto you, do ye even so unto them." D. T. F.

Aspects suitable to the various Kinds of Wall Fruit.—The following table, compiled by Mr. Powell, manager of the hardy fruit department in the Royal fruit and culinary gardens at Frogmore, is well worthy the attention of fruit growers:—

Cornish Strawberries and Bush Fruit.—About Penzance, and a little way in from the sea, around the adjacent villages there is splendid land and facilities for strawberry and raspberry culture. On flat, moist spots the raspberry and black currant can be grown beautifully to any extent, and the banks and slopes of undulated ground affords splendid opportunities of producing bounteous crops of early strawberries. I say early, and for this purpose early varieties alone should be cultivated, and that on the right aspect, viz., south and west. Intermediate sorts would prove almost a total loss, and the very latest varieties would not pay for their culture in Cornwall. By growing them, however, in northern counties, and in northern aspects, our English strawberry season might be greatly lengthened to the advantage of everybody.—JAMES BARNES.

The Vintage of California.—One of the leading wine-makers of California, who has given much greater attention to the vine crop than any other, this year will produce from 6,000,000 to 7,000,000 gallons of "must" or wine. Abiding to this estimate, the San Francisco *Bulletin* of October the 25th says—"This 'must' is worth about thirty cents a gallon, making an aggregate value of \$2,100,000. The grapes for wine-making sell in bulk at about one cent a pound. There is, in addition, a large amount of table grapes, raised for home consumption and for shipment. The choice varieties sell in the home markets at much lower prices than those for exportation, and the aggregate value of the fresh value of the grapes grown for other than home purposes at \$600,000. The aggregate value of the vintage for this year, in California, may be set down at \$2,500,000. The estimate may be a low one; but there are data to support it. Moreover, there is a large number of vines which are just coming into bearing, but will not produce a full crop until next year. From all quarters we hear that the quality of grapes was never better than this year. The dry weather has now come, and the vines have stopped working as noticed by us in Napa Valley, the yield of the hotter sorts of grapes was enormous. The proprietor of one vineyard, containing about twenty acres of choice varieties, said that the net returns would be not less than ten cents a pound, the entire crop having been engaged for the home market."

After the War.—The horrors of modern war do not vanish with the advent of peace as the French have often found out of late. Apart from the indescribable destruction of dwelling-houses and property of all kinds, great damage often occurs to the trees in the grounds of the houses. In many cases, they repair to their gardens and fields. In many nurseries and gardens in March of the present year there were unexploded shells, sometimes gathered and placed in fountain-basins as a precaution against their bursting. About l'Hay and Bourg-la-Reine, and in scores of other places about Paris and throughout France, the ground was literally strewed with shells a good many of them having been exploded, making it exceedingly dangerous to put the grounds in these former districts under cultivation. In some cases, by cutting down some trees that like numbers of others around Paris had been injured by shot and shell, suddenly struck by his hatchet a shell embedded in the trunk, and unhappily so as to ignite the shell, which immediately burst with frightful noise, rending the trunk into fragments. By a singular stroke of good luck neither the gardener nor other persons near at hand were touched. There have been many frightful accidents from shells since the war ended. A terrible accident occurred lately on the plateau of Champigny, where the

bombards of the 1st and 2nd December 1870, were fought. The share of a ploughman in common in the field was taken by a shell, which exploded in the ground, and the man was killed. The body of the man driving was scattered about the field in morsels; the horses were killed, and the plough blown to pieces. The trees suffered as much as the combatants; millions were cut down to the ground, and fine plantations left standing, here and there in the suburbs, were mutilated by shot and shell. Large boughs and trunks fell from the passage of a shell as you can see the gashed wood about three feet in diameter torn right through the tree. The shell seemed to have passed through the tree as easily as if there had been no wood within the bark. The tree was supported by about a foot of wood on each side, and did not seem to suffer. The shell entered the ground ten feet beyond the tree, and there burst. The gardener filled up with clay the jagged hole in the tree, which now remains erect where many of its fellows have fallen.

THE KITCHEN-GARDEN.

WATER.

The most pressing need in most gardens is that of water. Soil, manure, site, shelter, aspect—all, as a rule, have been more or less planned or provided for, but water has been expected to drop down from the clouds. And if it does not, how many gardeners have to go without it, or nearly so! Go without it! What does that mean? It means hard sticky vegetables, stunted leafy fruits, and small withered flowers; for water is the life, the very substance of most garden crops. As well try to make bricks without clay, as to grow succulent vegetables, luscious fruits, and fresh-scented flowers without water. And yet water is not only exceedingly scarce, but most recklessly wasted in nearly all English gardens: it is treated more as an enemy to be got rid of than a friend to help in every good work. It is carried off buildings into sewers, swept on the surface into the nearest ditch, and the earth tapped in all directions under the garden, that we may be rid of it. The whole or greater portion of that water ought to be saved up for future use. The rainfall throughout the greater part of the country is not sufficient for the majority of our garden crops. Sometimes for months during the most trying weather we have no rain. By storing our water we could regulate, and to a great extent equalise, the distribution. Common sense would tell us to open the lower cisterns when those in Cloud-land were closed or exhausted. But to do this we must store water in a more wholesale manner. I say store rather than raise water; for spring water, unless first exposed for some days to the ameliorating influences of the atmosphere, is too harsh and hard for the nourishment of plants. The only water taken care of now is the little that falls upon our roofs. All that flows from deep drains is wasted, when it ought to be collected in huge tanks.—FIELD.

NOTES AND QUESTIONS ON KITCHEN-GARDENING.

The Lima Bean.—This is a delicacy unknown to untravelled Englishmen, and quite worth a trial in some of your large English gardens. I consider it to be the best of the bean family, both when cooked alone and in the form of the well-known Indian dish called "Succotash," which is sweet corn in the green state cooked with Lima beans. The climate of England would not be hot enough for these beans, but after May there are generally empty frames, from early potatoes, &c., which might be used for them. The Lima bean is a climber, but by pinching in its tops, as is frequently done with scarlet runner, it may be kept in a dwarf state. It is shelled and cooked like peas, and it is also excellent dried and cooked in winter like haricots, but is much superior to them.—J. TAPLIN, South Amboy, New Jersey, United States.

Harvesting Herbs.—A good many herbs are used dry as well as green. The best state in which to gather them is when they first come into flower. At that stage their peculiar flavours have culminated. The general mode of drying herbs and treating them afterwards has been slovenly and filthy in the extreme. They have been tied in bunches, or in small bunches, and left to dry where they are without a little, and then packed up in some dusty spot until called for in the kitchen, where they have often made their appearance much more heavily coated with dust than distinguished by flavour. St. Clare, in "Uncle Tom's Cabin," implores all gentlemen who would enjoy their dinner to keep out of the kitchen. It is more necessary to caution those who relish the flavour of herbs not to ask to see their dry stores. All herbs should be dried quickly on open trays in a hot kitchen over a fire, and then packed up in a glass jar or bottle, and stored away in bottles closely corked. Kept thus, clean and air-tight, the strength and purity of the flavour is preserved for years. With the bottles closely corked and sealed, or bladdered like other preserves, a dinner liberally flavoured with herbs will be within reach any season summer or winter. In conclusion, I may add that the flavour of dried parsley is perfect.—*Quercus*.

Cultivation of Shallots.—I do not think it is generally known that shallots will grow much finer from seed than from the onion. I send you seeds, two of which measure over 71/2 inches in circumference. These should be sown in February prepared as for onions, namely, in a trench the ground two spits wide with a quantity of manure, and then tread the surface as hard as you can. Sow the seed in drills. The roots sent were grown by an amateur, and I doubt whether you can get any seed from a nurseryman.—C. A. [The specimens sent by our correspondent were very large and fine. They are the common, not the true, shallot. The common shallot is very nearly allied to the onion, and seeds freely. The true one does not].

THE MARKET-GARDEN.

MARKET GARDENING IN CORNWALL.

This is carried on chiefly about Penzance, which is the most westerly town in the county, and has a population of from 9,000 to 10,000. It is about ten miles from the Land's End, and 326 from London. It is defended from Atlantic storms by surrounding hills, and the atmosphere generally is soft and gently humid, particularly when the wind blows from south to west. Such a climate suits vegetation admirably; and the locality is renowned for its market-garden produce.

The land in the vicinity of Penzance has a substratum of horn-blende, rock, and slate, and is not surpassed in fertility by any in the kingdom. Its natural capabilities indeed are evinced by the luxuriance of the vegetation produced even under the hedges, fences, and odd corners. I never observed anywhere else such rank natural growth. A tract of land adjoining the town, consisting of about a thousand acres, produces a rental of more than £10,000 a year. An immense breadth of early potatoes is grown here, which are very remunerative, being ready to take up and send to market in May and June. They are conveyed in immense quantities to London, Bristol, Birmingham, Manchester, and to the markets of other large inland towns. On my first visit to Penzance many years ago, in May, I was surprised to have new out-door potatoes for dinner, and find that they were plentiful everywhere thereabouts. After the first crop is taken up, some of the land is planted again to produce a second crop, which comes in ready for the next year's seed. The early crop is, of course, planted in the winter and early months of the year.

The crop which succeeds early potatoes, and which is equal to them in importance, is white broccoli. This is sown in February and March, and is strong enough to put out at once when the potatoes are cleared off. This crop is grown to a very large extent, and is sent in crates by hundreds of tons during the early spring months to almost every market in the kingdom. This broccoli is generally close-headed, early and white, if attention is paid to breaking down the foliage over it, or to giving it some other slight protection, so as to prevent light in some measure and slight frosts reaching the heads. It is planted from two feet six inches to three feet apart.

Early cabbages, too, are pretty extensively grown about Penzance; its inhabitants and shipping population consuming annually many tons of them. Early rhubarb, as long as it is good, is sent inland to market; and asparagus is also cultivated to some considerable extent. I am surprised, however, that it is not more extensively grown than it is on such beautiful land as exists here, and under such a genial climate; more especially as it can be so easily packed—large quantities occupying but little room, compared with rhubarb or broccoli. Asparagus, too, is always a most saleable vegetable, and can be produced at least a month earlier than it can be about London or one hundred miles inland. Besides, in some of the Cornish caves and mines, it could be produced very early, and well blanched for those who like it white. Moreover, just a few miles from Penzance, is what is termed Asparagus Island, where asparagus grows in a wild state. There is also abundance of wild cabbage, seakale, and celery growing round the coast. Seakale is another saleable, wholesome vegetable, well worth a trial in this locality, where salt and sea-weed abound. It is astonishing what an acre of strong seakale roots would produce. If taken up and placed in the caves or mines, it would come on early, and a later portion could be left in a natural way to be covered with sand or light earth. If it only averaged, say sixpence per pound, an acre would produce a profitable result.

Globe mangolds are also grown to some extent after early potatoes. They are sown in a corner of the potatoe-field, and transplanted as the potatoes are cleared, and heavy crops are thus produced. Turnips, also, are sown; and, what very much astonished me the first time I went to Penzance, was to see the splendid healthy pieces of spring-sown turnips, in full-sized pulling order in April and May, a season when every turnip in the London markets of spring-sown growth is worth as much as an orange, inasmuch as first crops of them have to be produced on slight hot-beds, and those for succession on warm, sheltered borders, while, as a rule, they only last good a very short time, afterwards becoming strong, hot, and sticky. At Penzance the climate just suits these and other vegetables; and if I were inclined to grow asparagus and seakale for the million, that is the locality I should select on which to make a commencement.

Penzance, too, possesses the very climate and soil for early lettuces, which seem to have but little attention paid to them anywhere. Instead of a few common kinds of cabbage-lettuce, which are the sorts mostly cultivated here, I should begin with, at least, on a small scale, some of those fine Paris and London Cos Lettuces, which are sown in October, and planted out at the end of January and through February, in succession—why, they would grow splendidly in sheltered places, such as slopes behind large, high banks—and in March and

April they would be worth from sixpence to a shilling each, and often more. At the same time I should recommend enough only to be grown after the above date for home consumption. It is in the early spring only I should attempt their production, for markets at a distance, and the land would be early cleared, and not much robbed, for another crop.

Early carrots could also be produced at Penzance. If sown in July and August they would be fit to pull early in spring; thus competing with those from France, which sell them at a high price in the London markets.

As to manure, of course when two, and sometimes three, crops are annually taken off any land, however good, some must be applied; and I observed that about Penzance this for the most part consisted, in addition to sea-weed, or substances well suited for vegetable growth. It is applied pretty freely; but as respects horse-hoing, surface-stirring, trenching, and general pulverisation of the soil I must confess that I have seen these and other operations of that kind done better in other districts.

JAMES BARNES.

The Milaneo Sewerage System.—This is recommended by Mr. Child, of Oxford, in the *Times*, as being suitable for small towns and country villages. Its essential feature is the drainage of the houses into water-tight cesspools, which are emptied frequently, efficiently, and quite inoffensively by means of a barrel-cart, previously exhausted of air, and a hose. The barrel-cart then conveys the sewage to a depot at a convenient distance, where all that is saleable is sold to farmers, and the rest is manufactured into a kind of dry manure, which may be used in our little gardens without fear of damage to the plants, whereas sewerage works could not be established without an expensive provision for raising the sewage in order to render it available for irrigation. In such places the Milaneo system might be carried out with ease and at comparatively small outlay. A certain number of cesspools must be rendered watertight—a process not very expensive. One cesspool would serve for several cottages, and frequent emptying would be better than large size. Two Milaneo barrels must be procured, and these, when joined together, will hold twice as much as two common barrels, which, with about three men and two horses, form the whole of the apparatus required for testing the system upon a small but sufficient scale. On the day on which Mr. Child visited the depot near Milan, farmers' carts were waiting there literally in scores to obtain their supply of it, and he feels sure that if landed proprietors or farmers were to give the system a trial in this country they would find it well worth adoption.—[This system is, no doubt, a main cause of the deep verdure and luxuriance of the market-gardens outside the city of Milan.—W.R.]

NOTES AND QUESTIONS ON SOILS, MANURES, ETC.

Spent Hops.—Refuse or spent hops from the brewery are very easy to obtain in many localities, and, like coconut fibre and one or two other refuse materials, may be advantageously used in the garden. London nurserymen sometimes use them for ploughing small plots in, cutting them very much cheaper than any other loose and suitable material, and they are also occasionally used as a means of furnishing bottom heat. The heat generated is not by any means so strong as that afforded by other heating materials, but it is a most valuable source of heat, especially after the ground has been prepared, "nothing being more congenial to a boy of newly-struck cuttings of soft stuff in spring than to be plunged or seated on a layer of this." When rotted into mould, it makes a useful vegetable manure, and when thoroughly rotted, it is as good as leaf mould for mixing with common potting stuff, or in the soil for such things as cinerarias, fuchsias, and "soft-wooded" and bedding-plants generally. It is also highly useful as a mulching, and on light soils, liable to get too dry and to scorch and dry out the surface of the crop, a layer of this, two or three inches thick, on the soil of the crops, meant to be buried, produces a great improvement. Of course it may afterwards be dug in with advantage to the ground. It is one of those things that cannot be generally used or recommended, because not to be had everywhere; but there are many neighbourhoods in which it may be had at a nominal price, and in such places it will be found useful in the garden.—M.

Substitute for Gravel.—Having the misfortune to live in a part of the country where gravel is not very plentiful, most of my garden walks are paved with pitching stones, and I find it impossible to keep them clean. How does the reader suggest we may get rid of them? I have not yet begun to think of a substitute. Can any of your readers inform me of any ready supply for this nuisance? I have already tried salt, and found it of no use.—G. R. (Wherever gravel is scarce, clay is generally abundant, and it (clay) may be dug and burned into ballast for 2s. or 2s. 6d. per cubic yard. It should be hard burned, the lumps broken up, and passed through a half-inch sieve. Spread a layer, dry, three inches in thickness, over the surface of the paths, well roll it, then lay three inches of concrete over that, formed of five parts ballast, one part sand, and one part lime, and cover the whole low down with the back of a spade. This should be done in May, after the frosts are gone. Or a more durable but more expensive concrete may be formed by using Portland cement in the proportion of six to one. Gas tar, costing about 3d. per gallon at gasworks, run over the walls will prevent vegetation, and, to obviate the unsightly appearance, might be covered over half an inch or so with fine gravel or ballast.)

Books and Articles on Soils.—Can you recommend the best work on the varieties and properties of soil? A Student. [Much useful information will be found in M. J. Arkell's "Soils," p. 1-200, and in his "Soils and Manures," pp. 200-300, which is a continuation of the former, and contains articles on "Soils, their Origin and Composition," by Foxwells, vol. iv. p. 499; "Indications of Fertility or Barrenness," by Jno. Arkell, vol. v. p. 129; by Jno. Bravender, vol. v. p. 539; and by Schubler, vol. i. p. 177. "Power of Absorption," by H. S. Thompson, vol. xi. p. 64; by J. T. Way, vol. xi. p. 323; by ditto, vol. xii. p. 123; "On Agriculture," by Sir J. C. Broome, vol. vi. p. 125; "On the Varieties and Properties of Barrennesses and England and Wales," by J. Trimen, vol. xii. p. 45; "On the Properties of Clay," by J. Compton, vol. xvi. p. 389; "Chemical Properties of," by T. Jackson, vol. xvi. p. 106. And there is a good deal of information on the subject in Mr. Loudon's *Handbook* and in various other works.]

The Cleaning of Garden Walks.—Last summer I tried for the first time the efficacy of sulphuric acid for this purpose, and found it far superior to salt in many points. Procure the darkest, cheapest acid (about 1d. per lb.), and mix in a glazed pan with about twenty times its own amount of water, then have a copper can, pierced at the bottom, or better a copper water-can with a rose, with which apply it till the ground is just wetted all over, and no more; don't go

within six inches of the edges, nor make any spray fly as it kills wherever it touches. It kills every seed in the walk, and there are often hundreds dormant in every square foot. In all flint and clay gravels there is soda, and the acid unites with this, forming sulphate of soda, which is an efflorescent salt, that is a salt promotive of dryness, just as common salt is promotive of wetness; so and thus. And this salt is as white as snow, and it will soon become dry and clear. The action it applied in this spray will last all the season well. This deserves to become the universal method of cleaning a walk, for it is soon done and done with, it makes the walk so dry and pure, and it is as cheap as common salt, or even cheaper. It will be well to note that if the gravel is too full of lime the effect will be less.—A. D.

TOOLS, IMPLEMENTS, ETC.

A GOOD DIGGING-FORK.

The great importance of agriculture as compared with horticulture in America explains the fact that our inventive cousins have not made as great progress in improvements of horticultural as of agricultural implements, &c. Nevertheless, they are not quite at a standstill in this respect. Before leaving New York last autumn, I made a small collection of American garden tools, some for the sake of comparing the quality of their tools, &c., with that of our own; others, for their novelty and merit; and among these the digging-fork here figured is

an implement of proved excellence. My specimen is accurately shown in the engraving. The merits of this fork consist in its strength and lightness. It is strong enough for any ground or for any work, and withal without a trace of the clumsiness of the old digging-fork. The mode of fixing in the tines is worthy of attention. They are in two pairs, and passed through a large eye in the very strong iron apex of the handle, and then fixed in firmly by iron wedges, as shown in the cut. The section of the tine is also shown, but, though the fork cannot be better explained by an engraving than it is by ours, that fails to give the good idea of the article which seeing and handling it does. It ought to be in every garden. I am not aware that it can be purchased in this country, but if not, no seedsman or tool-merchant should have any difficulty in getting it from a New York house. I would strongly advise our nursery and seedsmen to keep it in stock, and some of our manufacturers to arrange for its production in this country.—W. R.

Moscow Exhibition, 1872.—Arboriculture and horticulture are to occupy a prominent position at this great International Polytechnic Exhibition. It cannot be expected, perhaps, looking to the distance of the place of exhibition, that very much in either of these branches will be contributed from this country; but it is obvious that, from nearer sources, it must be well supplied with abundance of materials that must be most interesting to arboriculturists and horticulturists, and which will well repay a journey to Moscow to see them. The *Arboricultural* division has been, we observe, sub-divided into the *Geography of Forests*; *Topography of Forests*; *Results of regular cultivation and artificial Arboriculture*; *Importance of Arboriculture in its relations to other branches of State Economy*; *Applied sciences: animals useful or injurious to forests*; *herbaria, dendrological collections, samples of the soil with analysis*; *Applied arts: drawings, models, photographs*; *Literature: books, maps, plans, and pamphlets*. The *Botanical and Horticultural* Section contains: 1. The exclusively scientific botanical part, comprising a botanical garden, with a systematic arrangement of the plants, and a botanic museum, with collections of various parts of plants, their raw and manufactured products, and with scientific data of general interest on the structure and growth of plants. 2. The applied part, including within it, fruiticulture, floriculture, kitchen-gardening, and other branches of plant culture.

The American and his Gardener.—Lackland has great faith, like almost all the men I ever met, in his study of physiognomy. About a man's temper or his honesty, he can hardly be mistaken, he thinks, if he can once set eyes upon him. He is therefore strongly disposed in favour of a stony, jolly-faced Irishman, who assures him he can grow as good vegetables as any man in America!—“And where, Sir?”—“In the boggy fields, Sir;—you could take cut of the flowers?”—“Oh, dear, Sir!”—“And the poultry, Patrick? you could look after the poultry, couldn't you?”—“And, indeed, Sir; that's what I can, there's never a man in the country can make hens lay as I can make 'em lay.” In short, Lackland bargains with Patrick, and reports him at the house-quarters “a perfect jewel of a man.” Lackland provides frames and glass for the early sash, and covers sash and panes with the best paper. The windows, he says, has probably a side all-a-stained. At the mere sight of it the Lacklands regret themselves with thoughts of crisp radishes and the mammoth purple fruit of the egg-plants. The seeds are all put in—early cabbage, cauliflower, peppers,

radishes—under the same frame, by the judicious O'Donohue. The cabbages and the radishes come forward with a jump. Their expedition forms a pleasant theme for the physiological meditation of Lackland. He is delighted with the stable manner, with the cabbage seed, and with the O'Donohue. He is inclined to speak disrespectfully of the seed of peppers and of egg-plants in the comparison. But the blunt O'Donohue says, “We may as well get a little more respect for the egg-plant as for the pepper.” Lackland is impelled on one of his visits to his brother to find in his fine kitchen the cabbages nicely pulled away; there is nothing left of them but a few sun-blackened stumps; the peppers and egg-plants show no signs of germination. “What does all this mean?” says Lackland; “the cabbages are dead, Patrick.”—“Yis, Sir—it's the hate, Sir. The sun is very strong here, Sir; we must give 'em a little more air, Sir.” And they get the air—get the air (by a little forgetfulness of the art of Patrick) nine days earlier than the pepper and egg-plant. A fortnight's time of expectation do not appear. “How's this now, Patrick, no stars?”—“Not yet, Sir; the seed's good, Sir.”—“It's all Thorthurn's seed.”—Then, of course, it ought to be good, Sir; but, ye see, there's a date of chattery nowadays. And Patrick grubs away with a great deal of misdirected energy—slicing off, in the heat of his endeavour, two or three of Mrs. Lackland's choicest rocket larkspur; whereupon that lady comes down upon him with some zeal. “Larkspur! and that's a larkspur, is it, M'am?” (scratching his head reflectingly) and, before I ever thought 'twas a larkspur. Pity, pity; and so it was, indeed, a larkspur? Well, well, but it's lucky it wa'n't a rosebush, M'am.”—J. D. MICHENER.

OUR CALENDARS.

It is our intention to furnish monthly a General Calendar of Garden Operations in each important branch of gardening. The different departments will be written by cultivators who have proved themselves to be unusually successful in the particular department placed in their hands. In addition to this, we shall always supply, weekly, except on the days on which the Monthly Calendars appear, a concise remembrance as a guide to amateurs. Mr. James Barnes, late of Bicton, will write the monthly calendar for the Kitchen-Garden, Pinetum, and Arboretum; Mr. Tilney, of Welbeck, the Fruit-Garden, both in the open air and under glass; Mr. Baines, of Southgate, the Stove, Greenhouse, and Conservatory departments; Mr. Westland, of Withey Court, will take charge of the Flower-Garden; Mr. R. Dean, Florists' Flowers; while, Herbaceous, Alpine, Aquatic, and Bog Plants will also receive their share of attention. As a rule, the writers of these divisional sections will be changed annually or biennially, so as to obviate monotony, and to secure the best advice in such matters from widely different districts of the kingdom. These Calendars will commence in our next number, and will generally be published at the beginning of each month, so that our readers may avail themselves in due time of the directions given.

The Ivy as a House Plant.—Our very old friend the Ivy Green is a first-class indoor plant. We have known him so long as an inhabitant of silent and gloomy places that few perhaps would think of introducing such a child of the woods to civilised house-life. However, judiciously placed, no plant will furnish a better result or live more contentedly indoors. As a screen plant it is admirable, and much used in various places for that purpose in the drawing-room. It is planted in long narrow troughs and trained to an erect trellis, placing the trough in another ornamental trough of some kind of earthenware, so that the moisture necessary may not descend to the carpets. It is in the first instance pretty well grown on the trellises before being placed in the house. But it is not only in places where numerous gardeners are employed to attend to such screens that it may be enjoyed. If in any hall or place where fire-heat is rarely used, all that we have to do to form a screen of the richest ivy is to plant it in a box of rich earth and train it as may be desired. The best of all kinds for this purpose is the common Irish ivy. It may indeed be grown in almost any part of a house if supplied with soil and water and trained a little at first. I have seen a beautiful effect produced by its means in an entrance hall—the deep box in which it grew being placed in a niche and the shoots allowed to fall down so as to form a curtain of rich leaves.

Tree Guides in the American Deserts.—Dr. Newberry says: “For a time we were often deceived by the poplars and willows, regarding them as owing a large portion of their beauty in their vicinity to the streams flowing the year. Alders we found much better guides to water, as they will only follow the courses of the streams just as far as they are permanent, and no further; and we never failed, even near the close of the dry season, to find the roots of the alders washed by living water.” The American aspen (*Populus tremuloides*) is abundant in the region east of the Cascade Mountains and Sierra Nevada, forming a marked feature of the vegetation. It is the root of these timber, which is the chief material for the large logs of wood the Shoshone Indians use for their houses. Hence it is seen in long lines of trees of small size, marking the courses of the many mountain streams which are in summer absorbed by the arid surfaces of the plains soon after leaving the mountain sides.

Horticultural Hints for Everybody and Always.—Cultivate acquaintances, if desirable; but, if cut them. Never sow the seeds of division. Feed your flower-bed. Invest in stocks. Get as much heartsease as you can. Fern-growers, don't be too fierce in your rivalry; remember the war of the Frond. (c). Attend to wall-flowers and the like. Don't be afraid of a little competition, and a little competition. Don't panic. Avoid flowers of speech. Pot—a lot of money at racecourses. “Bedding out” is good for plants, but not for friends. Take the advice of the sage, or you may rue the consequences. Ladies! success to the great rose show—on your cheeks—and may you always be eye-bright! N.B.—Never pay your bets in fox-gloves.—*Punch's Almanac*.

THE GARDEN.

"This is an art
Which does menu nature : changes it rather ; but
THE ART IS NATURE." —Shakespeare.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37 Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER.

The Name and Address of the writer are required with every communication, though not for publication, unless desired by the writer. Letters or inquiries from anonymous correspondents will not be inserted.

All questions on Horticultural matters sent to "THE GARDEN" will be answered by the best authorities in every department. Correspondents, in sending queries, are requested to write on one side of the paper only.

Readers who may find it difficult to procure the numbers regularly through the newsagents, may have them sent direct from the office, at 19s. 6d. per annum, or 9s. 9d. for six months, payable in advance.

THE FLOWER GARDEN.

NOTES MADE IN THE "TIME OF ROSES."

BY S. REYNOLDS HOLE.

We may congratulate each other, we who love the rose, that never was her excellence in this floral world so conspicuous, so supreme, as now. Some of us may be sceptical as to the advances made and the conquests won by "the march of intellect," and some of us may even dare to doubt (without denying that in the matter of velocity there are advantages attached to a telegraph which we find not in a Pickford's van) whether the vaunted "progress of civilisation" itself is not mainly a procession of trumpets; but we must all believe in the development of beauty, which our eyes have seen, among the flowers generally, and specially in their queen, the rose. Recollect, ye who can, the pelargonium, the cineraria, calceolaria, fuchsia, twenty years ago, and see what amplification and symmetry of form, what variety and intensity of colour, has been granted to their descendants! But to none of these has come such an accession of tint and of form as to the rose. To her of all "the daughters of the year," of all flowers in hothouse, greenhouse, or garden, we may reverently apply the words of the wisest and greatest of all gardeners. "Many daughters have done virtuously, but thou excellst them all."

I have "a list of roses grown at Caunton Manor," made at a time when I may be said to have taken my degree, after four years' study, as a rosarian, namely, in the year 1849, and at the end of it there is a summary consisting of 362 varieties. Of these, how many, think you, are now available for the censor's eye at a rose-show? *Two only*—Adam and Devonensis. And 355 have long ago disappeared from the scene, leaving with the two fore-named, Blairie No. 2, still one of the loveliest, but expanding too soon for exhibition; Coupe d'Hebe, charming as a tree, but small in its individual flowers; Comte de Paris, a bright, fresh, tea-scented rose; Géant des Batailles, retained as pensioner for brilliant service on the tented field; and Safranot, beautiful for the button-hole when Madame Falcoet is away. All gone but these; and yet there was a time when they realised our ideal, and satisfied our desire; when we believed that Grandissima deserved her title, and took off our hat to Reine des Beautés, and should have called a man out had he hinted a suspicion as to that rose's modesty who said of herself, "*Reine ne me surpasse.*" We were never tired of admiring our Aurora, our Aimée Vibert, our Beauty of Billiard (not raised by "Jonathan," or Roberts' père, but red as the ball which they love to see in proximity to the middle pocket), our Celina and Ceres, our Daphne and Emerance, our Mélanie Cornu and New Village Maid, our Ophurie and Puicheric, our Reine des Vierges, and our Sophie Durval.

And then, because we appreciated that which was given to us so heartily (and found, as always, in such an appreciation the main secret of earthly happiness), because loveliness is not the cause only, but the result, of deep and innocent love, new

* See p. 5, ante.

gifts were granted, and new graces shone. Because we served so loyally, so faithfully, we were commended as true knights for higher enterprise, admitted to a more noble company, and rewarded by the smiles of yet more radiant beauty.

First there came to us a great champion, a mighty conqueror flushed with victory, whom we called our Giant of Battles. We made him by acclamation our commander-in-chief, and as he glowed in brilliant uniform at the head of his troops, with a superior form and brightness, we thought that we had found perfection; and when a report reached us that an officer, yet more handsome and more vigorous, was to be promoted over him, there was doubt, and dismay, and disorganization in Queen Rosa's Army. But when General Jacqueminot came upon the scene, incredulity and indignation disappeared from it, arm in arm, and every soldier accepted for his chief this General Jac—the Giant-killer. We were quite sure that now, at all events, our hero was invincible. To every war of the roses, he came, and saw (no, not saw, for he had never an "eye"), and conquered. The hero of a hundred fights, he was entering upon a second century of triumph, when music, martial, jubilant, audacious, precluded the approach of a rival. "What would na' dic for Charlie?" was the air selected, and presently Royal Charlie himself (I can only explain the sobriquet of Lefcuvre by supposing it to be a corruption of *la fièvre*, the fever, which raged among rosarians on his arrival) drew near, with such an overwhelming power and majesty that the general at once tendered his sword, and himself led the king to his throne.

A like development of beauty has been manifested in the other varieties of the rose. In white roses, our old favourites, the Princesses Clementine and Lamballe, Mesdames Hardy and Zoëtmans, have been superseded at court by Mesdames Rivers and Vidot, by Mademoiselle Louise Magnau, the beautiful Baroness de Rothschild, and others. In pink roses, our well-loved Duchess of Sutherland and Baronne Prevost are supplanted by such flowers as Madame Furtado, Thérèse Levet, and Marquise de Castellane. In yellow roses, our "Jaune de Smith," our Harrisoni, Persian Yellow, and Solfaterra have succumbed before Maréchal Niel; and in the darker varieties, our Boula de Nanteuil, D'Aguesseau, and Oui, "pale their ineffectual fire" in the presence of Pierre Notting, Prince Camille de Rohan, and Xavier Olibo.

And every summer brings some accession (I once heard a gardener describe a new chrysanthemum as "a beat on Bob") in colour or in form—some novelties, of which more anon.

Meanwhile, to whom shall we give our thanks and our praise, when we have proffered them reverently to the Giver of all good—to whom, as being His agents? Not to botanists. Not to men of science, falsely so called, who never "raised" a flower in their lives. Not to the anatomist, who glories in his museum of malformations, and describes, but prescribes not for, disease, who would rather dissect the dead than revive the dying, and has more pleasure in his herbarium, with skeletons dry and sere, than in gardens of life and beauty. Not to him, but to the gardener, whose love and skill and industry have, humanly speaking, gained these treasures for us; who tends with a complete devotion, blends with all the wisdom of experience and thought, and waits with an untiring hope. To him, our thanks; to him, and to such as him, to all gardeners who deserve the name, be they owners, occupiers, or servants, whether they "walk in silk attire," or wear purple baize, we dedicate and inscribe THE GARDEN.

THE BOG-GARDEN.*

As to the planting of the select artificial bog, all that is needed is to put as many of the undermentioned subjects in it as can be obtained, and to avoid planting in it any rapid-running sedge or other plant. When this is done, all satisfaction with the bog is at an end. Numbers of carexes and like plants grow so rapidly and densely that they soon exterminate all the beautiful bog-plants. If any roots of sedges, &c., are brought in with the peat, every blade they send up should be cut off with the knife just below the surface; that is, if the peat cannot be pulled up from being too near some precious subject one does not like to disturb. All who wish to grow the tall

* See p. 7, ante.

sedges and other coarse bog-plants should do so by the pond-side or in one or more moist or watery places set apart for the purpose. Given the necessary conditions as to soil and water, I can testify that the success of the bog-garden will depend on the continuous care bestowed in preventing rapidly-growing or coarse plants from exterminating others, or from taking such a hold in the soil that it becomes impossible to grow any delicate or minute plant in it. Couch and all weeds should be exterminated when very young and small. The following are the bog and marsh plants at present most worthy of culture; but there are numbers not yet in cultivation, equally lovely.

A SELECTION OF CHOICE BOG-PLANTS.

Anagallis tenella; *Botomus umbellatus*; *Calla palustris*; *Caltha* in var.; *Campanula hederacea*; *Chrysobactron Hookeri*; *Coptis trifoliata*; *Cornus canadensis*; *Crinum capense*; *Cypripedium spectabile*; *Drosera* in var.; *Epipactis palustris*; *Galaea aphylla*; *Gentiana Pneumonanthe*; *Helonia bulbata*; *Hydrocotyle bonariensis*; *Iris graminea*, *Monnieri*, *ochroleuca*, *sibirica*; *Leucojum aestivum*, *Hernandezii*; *Limnaea borealis*; *Lobelia syphilitica*; *Lycopodium* in var.; *Menyanthes trifoliata*; *Myosotis dissitiflora*, *palustris*; *Nicerebergia rivularis*; *Orcis latifolia* and vars., *laxiflora*, *maculata*; *Orontium aquaticum*; *Pinguicula* in var.; *Primula Munroi*, *sikkimensis*; *Rhexia virginica*; *Sagittaria* in var.; *Sarracenia purpurea*; *Saxifraga Hirculus*; *Spigelia marilandica*; *Swertia perennis*; *Tofieldia* in var.; *Tradescantia virginica*; *Trillium*.

The above are most suitable for the select bog-bed kept for the most beautiful, rare, and delicate plants; and among these, as has been stated, should be planted nothing which cannot be readily kept within bounds. To them lovers of British plants might like to add such native plants as *Malaxis paludosa*; but it is better, as a rule, to select the finest, no matter whence they come. Some may doubt if the American pitcher plant, *Sarracenia purpurea*, would prove hardy in the open air in this country. It certainly is so, as one might expect from its high northern range in America. It will thrive in the wettest part of the bog-garden. In America I usually observed the pitchers half buried in the water and sphagnum, the roots being in water. In British gardens it usually perishes from want of water.

The following is a selection of vigorous marsh and water-side plants which may be planted in any sufficiently moist positions, and left to struggle with each other for existence:—

A SELECTION OF VIGOROUS MARSH AND WATER-SIDE PLANTS.

Acorus Calamus, *gramineus*; *Alisma* in var.; *Aster Tripolium*, and coarse varieties; *Butomus umbellatus*; *Calla ethiopica*, *palustris*; *Caltha palustris*; *Carex paniculata*, *pendula*, *Pseudo-cyperus*; *Cyperus longus*; *Epilobium hirsutum*; *Equisetum* in var.; *Eriophorum* in var.; *Eupatorium* in var.; *Glyceria aquatica*; *Gunnera scabra*; *Hibiscus* in var. (North American herbaceous kinds); *Hippuris vulgaris*; *Houttuynia cordata*; *Iris Pseudacorus*; *Leucanthemum lacustre*; *Lysimachia thyrsiflora*; *Lythrum Salicaria*, and its var. *rosea*; *Myosotis palustris*; *Oenanthe fistulosa*; *Osmunda* in var.; *Phormium tenax*; *Pontederia cordata*; *Pyrerthrum serotinum*; *Ranunculus aquatilis*; *Rinaria*; *Rumex Hydrophylathrum*; *Sagittaria* in var.; *Scirpus lacustris*; *Sparganium* in var.; *Typha*, all the kinds.

A group of the boldest of this last selection is strikingly effective in the picturesque garden.

CONDUCTOR.

SEDUMS AND SAXIFRAGES.

We are beginning to appreciate the advantages in an artistic point of view of middle and neutral tints, as well as bright colours in the pictures we paint in our gardens with living plants and flowers, and we have, fortunately, at command, and amenable to cultural skill, a tribe of plants that enables us to shade off our floral sketches by soft gradations of brown, and grey, and green. The hardy Sedums and Saxifrages not only enable us to do this in summer, but they help us to relieve and brighten our winter gardens; and, associated with early bulbs and those spring flowers which are deficient in foliage, they give the balance of green that is required and carpet the dull, dried ground with their soft and spring-like verdure; and their value in the winter and spring garden is not only in the pleasing effect they produce. The bulbs and roots of plants with which they are associated are effectually screened from the effects of frost, or trying changes of temperature. No ordinary frost would penetrate a healthy tuft of *Saxifraga hypnoides*. I have two beds filled with *Scilla bifolia* and *Scilla*

sibirica, the surface of which is brightened with a selection of Sedums, Saxifrages, and Sempervivums. Fragile as the flower stalks of the Scillas seem, they force their way through the green carpet of Stonecrop and Saxifrage, and seem to enjoy the association.

It is only by planting in masses that we are able to realise the effect these simple plants are capable of giving; and to obtain vigorous examples presenting the distinctive characteristics of the tribe, it is best to divide and replant either annually or biennially, according to the growth of the variety. Although many of the Saxifrages will live almost anywhere, starvation no more agrees with them than with other plants. This may be readily seen, if the dwarfed, stunted, pot-bound specimens sometimes found in a botanic or nursery collection are compared with plants placed in circumstances favourable to their full development. The hint that is conveyed to us by plants that spread out and extend over the ground annually, should be understood to mean that one year's growth and occupancy of the ground exhausts its fertility, and new soil is required for further growth.

I have mentioned the utility of some of the Sedums associated with bulbs. Their application in the spring garden may be extended to many combinations. Masses of *Erica herbacea* are brightened, and thrown up, and rendered more effective by a base of *Sedum acre aureum*. The same Sedum, planted with *Lamium maculatum*, helps to bring out the rather dull variegation of that spring plant. Combined without adventitious aid, a mass of varied Sedum and Saxifrage is sure to invite attention and admiration. Thus, a bed composed of a central mass of *Saxifraga geranioides*, followed by a broad green band of *Saxifraga hypnoides*, succeeded by *Sedum glaucum* and *Sedum acre aureum*, and fringed by *Sedum rupestre*, is not the least attractive bed in the spring garden. Next year I hope to employ that gem amongst Saxifrages *S. longifolia*. That bright star is, with me, somewhat nebulous as yet. I may, perhaps, be allowed to indicate for your amateur readers a few of the most effective and manageable Sedums and Saxifrages for winter and spring gardening. Foremost on the list is certainly *Sedum acre aureum*. The Sedum known as *S. glaucum* in London gardens is of equal value with the foregoing, and affords a very useful middle tint of light grey. *S. rupestre* assumes a crimson tinge in the spring.

Amongst Saxifrages, *S. longifolia* stands conspicuous. Its beauty is due to the accuracy of its star-like form. *S. oppositifolia pyrenaica* is distinguished by the profusion of rosy blossoms it produces early in the year. *Saxifraga hypnoides* and its varieties are essential in a collection of these, *S. juniperina*, *spathulata* and *pulchella* are useful species, affording tufts of the brightest green; *Saxifraga cespitosus*, *S. cerasophylla*, and *S. geranioides*, are also hardy and easily managed kinds, which may be usefully worked to any artistic arrangement that may be desired.

Belvoir.

WM. INGRAM.

Notes on Hardy Plants.—I now adopt the plan of mulching my mixed border and never digging them, and in some cases I go further. On my peat-bed and fernery I do not remove the fallen leaves that may accumulate there, but I cover them over with a slight mulching of cocoa-nut refuse. In this way I imitate nature, who, by a thick covering of leaves, provides against the ill effects of plants throwing themselves out of the ground. The majority of plants die every year; but nature meets that by a mulching of leaves, which become soil. If I could dare to brave the imputation of untidiness I would not cut anything down till the spring. You may be sure the flower-stems and decaying root-leaves are an immense protection in winter. I have mixed borders right up to the drawing-room windows. Of course I am rather particular what plants I put there. As an instance, I will just describe to you one small bed near the drawing-room. It is perhaps ten feet long and eight feet wide. The back is filled with *Arundo Ragonoskii* and *A. falcatu*, one corner with *Pistacia terebinthus*, the wall with *Bignonia capreolata*; another is filled with a large clump of *Zauschneria californica*, and a fourth with *Acanthus lotifolius*; at other stations are shrubs of *Berberis Wallichiana* and *Hydrangea quercifolia*. The centre is filled with anything, and near the edge are *Narcissi*, *Lathyrus tuberosus*, &c. There is no formality, and there is plenty of interest. Lilies never did well here, so I put on my considering-cap about two years

ago, and made them a special bed for themselves. I chose the *lowest* part of the garden. There I dug out my bed two feet deep; I filled six inches of this with brick and other rubble, and the remaining eighteen inches with coarse river sand and garden soil in equal quantities. In this I planted my lilies, putting no manure; but, when they had been in a year, I mulched the surface with rotten manure, and shall do this again. Hitherto the result has quite satisfied me. The spaces between the lilies I intended to fill with Oxalis, but last winter destroyed many of them. Those that survived evidently like the soil much, and in the front, now, I have Croci, and other small bulbs. I have a large bed of Yuccas, and another bed edged with Erica, but the soils are totally different—one is a stiffish clay, the other sand. Have you ever known *Arundo Donax versicolor* really hardy? I have not. *Polygonum cuspidatum*, grown in the lawn, is a grand plant with me, measuring ten or eleven feet high. I should add, that no one should ever condemn a plant for its first year's show. Many plants do not show their full beauty till well established. As regards *Adenophora*, the best is *A. versicillata*, but it is scarce. I once had it fine, but lost it by dividing for a friend. With respect to *Alstroemerias*, nobody need trouble about planting them deep; they will soon get deep enough. I have been trying to destroy them in one place, and cannot, because I cannot reach them. *Aponogeton distachyon* is quite hardy in water that does not freeze (running water). It is so grown at Edinburgh. The very finest *Aquilegia* is *formosa*—bright red. *Arum crinitum* has the peculiarity of not putting in an appearance at all the year after flowering—at least, that is its habit here. *Asarum virginicum* is well worth growing for its mottled leaves; but where can it be got? *Asarum* is one of the very best plants to grow in dense shade, or in dry places under trees.

Bitton.

W. H. ELLACOMBE.

WATER-MARGINS

MANY people like a little water in their garden, and make a little pond, or perhaps a big one if they can afford it. Yet how few of these ponds, lakes, or whatever they may be called, ever give the satisfaction desired, and why? Obviously, because we make our little bits of water too bold, too puny, and altogether different from what we find in nature. The chief difference between the two lies for the most part in the setting or margin, about the treatment of which there is much misconception. Let us, therefore, give to water-margins some little attention, in order that we may discover what it is they require to set the water off to advantage. I was, a little while ago, inspecting a piece of water, the margin of which I could not help admiring. At one part a sweet flat meadow stretched a long narrow lip completely into the water, which a little

Margin of Loch Achray.

farther on was overhung with trees and bushes; then came a patch of reeds, half concealing the pebbly bed of the mouth of a little brook; bushes again, and in one part little trees, through which the water looked, as it always does, under such circumstances, particularly pleasing. Water splashing and dashing in some places, and sweetly flowing in a long suggestive line in others, has often engaged the pen of the poet, and is not unfrequently found on the canvas of the painter, but we seldom meet with it in gardens. We have a dreadful way of making the banks turn down and dip stiffly into the water, and of making the margin quite formal. It is a mistake to call neatly-rounded margins an imitation of nature; and yet they are fondly believed to be so. We must not depend on the

mere presence of water for striking effect; it should be tastefully relieved and made presentable in a framework or margin skilfully conceived; just as a nosegay is relieved and softened by the leaves of ferns and other greenery with which it is surrounded. The accompanying illustration, showing the beautiful margin of Loch Achray, which I sketched last autumn, will indicate how immeasurably superior nature's margins are to those with which we are satisfied in our gardens.

A. D.

THE FLOWER-GARDEN, &c., FOR DECEMBER.

BY G. WESTLAND, WITLEY COURT.

Flower-Garden.—Here the summer occupants of beds have been cleared off, and they are now, for the most part, replanted with spring-flowering plants. If bulbs for early blooming are not yet planted, make it a rule to plant nothing without a green ground-work of some kind to cover the soil. *Arabis*, *Aubrieta*, *Violets*, *Sedums*, *Saxifrage*, *Daisies*, *Primroses*, *Forget-me-Nots*, and similar plants are admirably adapted for the purpose. Decorating the spring garden so as to yield a constant succession of flowers constitutes one of the most interesting phases of modern flower-gardening. I plant bulbs by the thousand; but I cover the raw earth about them with an evergreen or variegated carpet. How this is done will be stated in due time. In the summer arrangements much may be done in the way of substituting for common-place effects refined and artistic combinations. With the great variety of hardy ornamental plants of all forms and colours which we possess, we have material enough of the most varied and effective description for making noble and striking groups, thus lessening to a great extent the use of tender bedding-plants, which would be a decided gain. Whilst thus advocating, however, greater variety in the way of planting our beds, let it not be inferred that I do so to the exclusion of tender exotics and sub-tropical plants. On the contrary, I believe them to be indispensable, in the highest sense of the word, to effect, when used in moderation. For a few well-arranged beds may give the greatest amount of satisfaction. Our requirements for tender plants have become so great as to make it a matter of serious importance as to how they are to be managed, as adequate accommodation and labour have not by any means kept pace with the mania for high colouring. If not already done, protect all choice plants likely to suffer from frost, and endeavour to render such protection as little objectionable as possible, by finishing off with a garniture of evergreen sprays. Magnolias and standard *Buchs* should have some slight covering of spruce or light evergreen branches, and the stems should be bandaged with hay. The Pampas Grass often succumbs to the severity of our winters. In its native habitats this grass is parched up whilst at rest; therefore we ought to preserve the roots in as dry a state as possible in winter. See also that *Canna* roots left in the ground have sufficient protection. Prune and nail hardy creepers upon walls and pillars, and tie as much as are on lattice-work. Holly-hocks, allowed to remain out all winter, secure against wet and slugs by placing cinder-ashes round them. See that plants requiring support are secured against high winds. Take advantage of frosty weather to turn compost heaps, and lose no opportunity of collecting refuse to rot down for manure.

Herbaceous and Alpine Plants, &c.—Annual and biennial plants raised in summer and early autumn may now be transplanted into the positions in which they are to bloom, giving them in all cases light and well-drained open soils. Lilies of all kinds may now be transplanted, having the positions fully prepared previously, so that they may not be kept out of the ground. Lilies often suffer much, or perish, from being exposed to the air. All other bulbs may be transplanted now. Alpine plants will require little or no attention, beyond scattering a little fine earth or leaf-mould or cocoa-nut among such as have grown or pushed up a little out of the earth, and which are in consequence likely to perish from cold drying winds. Herbaceous plants may be transplanted with safety in almost any weather, though it is not desirable to move them when the ground is frozen deep.

Shrubberies.—As soon as the leaves have fallen, rake them together, and cover them with soil, so that when they have rotted they may be returned as manure to the ground from which they have been collected. Avoid the usual practice of digging shrubberies; for there is no greater mistake in reference to garden management than periodically root-pruning plants, the majority of which have not a root to spare. Shrubberies should not show any margin of raw soil, for the covering of which we have thousands of dwarf evergreen plants that might be made to look very effective in such situations. Bulbous plants, too, pushing their way through the low green boughs are by no means unwelcome. I have seen a terrace-slope planted entirely with *Juniperus sabina*, through

which, in the spring time, thousands of bulbs throw up their flowers; and nothing could be more charming. Shrubberies *en masse* should consist of a well-chosen combination of the finest evergreen and flowering shrubs, so arranged as to furnish the greatest amount of variety and striking effect.

Rose-Garden.—Transplanting may now be done with advantage; and if new kinds have to be procured, the sooner they are got and planted now the better. Before planting, however, take care that the stations for them are properly prepared by removing part, if not the whole, of the old soil to the depth of eighteen inches, and replacing it with fresh compost of the proper kind. Everyone knows that the rose delights in a strong soil, and that it will take any reasonable quantity of rich manure. Hence each variety, after it is planted, should be mulched with rotten dung; and the beds will also be all the better for a similar supply. When planting, make the plants secure by means of stakes. But do not prune, before cutting off the points of straggling branches, until frost has left us. Some of the more tender kinds of Tea and Bourbon roses may require protection; dwarfs may be pegged down and covered with dry fern. And a handful of dry fern fronds drawn into the head of a standard rose, and well secured, is not a bad protection, that is if the snow is not allowed to lay or melt and run into it. Dryness is the point to be attained. In some localities it may be requisite to lift Tea-roses and place them under protection for the winter.

Pits and Frames.—As a general rule everything in these should be kept as quiet as possible, and no encouragement given to induce a weakly growth. Give an abundance of air on every favourable opportunity; using fire-heat only in case of frost, or to expel damp in wet, foggy weather. Remove decaying leaves and water sparingly. Alternantheras and similar plants, which are so useful in pattern-bedding, should not be overlooked, but afforded heat of from fifty-five to sixty degrees. Violets should be uncovered on fine days; giving them occasionally weak manure-water. They are impatient of much nursing.

FLORISTS' FLOWERS.

AUCUBULAS in cold frames will now be at rest. Any decaying leaves on them should be removed as they appear, and when the weather is mild, plenty of air should be given them. The foliage, and especially the hearts of the plants should be kept perfectly dry; water must be given sparingly, and chiefly to those plants which appear to flag. During frost the frames should be kept closely shut.—Carnations and Pincées in pots, which will also be in cold frames, should be kept as near the glass as possible. Plenty of air should be given them. Water should be given only in the morning, and withheld altogether in frosty weather. Decaying leaves should be removed, the surface of the soil kept clean, and the plants must not be crowded too much together.—Cinerarias should be kept near the glass, but secure from frost. Air should be given them, but they should be kept free from cold draughts, which curl their leaves. Keep the plants growing by shifting them into larger pots as required, and kill green-fly by means of fumigation.—Dahlias roots should be kept dry and free from frost, and they should be looked over occasionally in order to remove decaying tubers.—Hollyhocks may be wintered in a dry, cold frame, where air can be admitted. Old roots in the ground should be lifted, put in pots, and placed in a cold frame to get cuttings from in February. All decaying leaves should be removed as fast as they appear.—Pansies in beds should be secured against wind, by means of pieces of sticks or pegs, and in hard weather protected by placing a few small branches of spruce firs among them. The beds should be fully six inches above the paths in the centre, and rounded, in order to throw off rain. In cold, damp localities, it is best to lift the plants and to plant them in a cold frame, or the smaller ones can be put in small pots.—Pinks should also have their branches similarly secured, and after heavy rains it is well to stir the surface soil of the beds, as they get beaten down by heavy autumn rains. Should the plants be lifted by the action of frost, they should be gently pressed into the beds when a thaw sets in.—When the Ranunculus is planted in somewhat heavy soil, it will be well to lay a few boards, or some other covering, over the beds to throw off the rain. Excessive moisture at this season is injurious.—Verbena, whether as old plants for stock, or as cuttings in store pots, should be placed in a warm, dry position near the glass in a greenhouse, and kept only moist enough to keep them alive. The plants should also be kept as clean as possible.

R. DEAN.

Asphalt Roads.—These have been subjected to a severe test in London, and have been found to answer well. What a happiness for those who have cars! A wagon conveying a large granite block, the weight of which, including the vehicle, was twenty-three tons, passed over the asphalt in Cheapside the other day without making any abrasion, or causing it the slightest injury. The police are under the impression that fewer horses fall, and are certain that no more fall on it than upon granite. It has, therefore, been decided to pave many other streets with Val-de-Travers compressed asphalt.

PYRETHRUMS.

A FEW words on the culture and propagation of these now somewhat fashionable plants may not be unacceptable to many who have a garden, and, perhaps, very little glass. They are, I need scarcely say, perfectly hardy, and I know of no family of plants that has made such advances during these last ten years as the Pyrethrums. They have now become as beautiful as many of our China Aster, and they have the advantage of flowering at a different season, which makes them more acceptable, viz., from May onward through the summer months.

If required for the ornamentation of herbaceous beds or borders, where the ground is in "good heart" that is what they want, and if tied to some slight supports while in flower, they will afterwards take care of themselves. As the old flower-stems die down they should be removed, as that will give the plants fresh vigour to throw up flower-stems again.

If intended for pots for exhibition purposes or otherwise, they should be taken up from the ground in spring, as soon as they show any appearance of growth, picking out carefully the old soil, and potting in good fibrous loam and rotten dung or vegetable mould, using a moderate amount of drainage, and plunging them in leaf mould, or something of that kind, to keep them from drying at the roots. As they advance in growth they require a good supply of water; and, when coming into flower, a little liquid manure will prove beneficial to them.

As regards propagation, the proper time for that is early in spring. Take the plants up, shake all soil from them, and pull them to pieces, putting them in small pots, and placing them in a cold frame for a few weeks, until they become established. Care should be taken not to keep them too close, as they are apt to damp. When established they may be planted out in their proper quarters.

The following are all first-rate double kinds, varying in colours from white, bluish, yellow, and red, to dark crimson, being, in fact, a selection from about fifty varieties, viz.:—

Boule de Neige.	Gloire de Stalle.	Mrs. Dix.
Carneum.	Gustavo Hertz.	Rev. J. Dix.
Candidum.	Hermann Stenger.	Nancy.
Delicatissimum.	Imbrication.	Nepressis.
Dr. Livingstone.	Iveryanum.	Niveum.
Elegansimum.	Luteum.	Paul Journa.
Eximium.	Lady Blanche.	Roseum.
Floribundum.	Madame Billiard.	" album.
Fulgens plenissimum.	Munier.	" perfection.
Galathaea.	M. Barral.	Rubrum.

Exotic Nursery, Tooting.

T. BROWN.

NATURE'S GARDENS.

NIAGARA.*

A CHIEF reason for speaking of this oft-described spot is a desire to plead for the preservation intact of such a magnificent scene. The whole is so vast and so far out of man's control that probably nothing man or machinery will do can ever cause it to be other than a place of the highest interest; but it may be injured and deteriorated in various ways—nay, it certainly will be so if precautionary measures be not taken. One of the islands is already the home of a common-place paper-mill; persons are here and there allowed to levy black-mail on spots that ought to be quite free to the public; the "leprosy of White Hotels" has broken out in one or two spots, and a "museum" (stuffed with double-headed calves, a fine specimen of a "mummy," with a full red beard, &c.), the proprietor of which assured me that his collection was far finer than that in Great Russell-street, is allowed to plant itself by the margin of the noble river. Looking at the magnificent Horse-shoe Fall from the central island, the eye is caught by a wretched block of a "tower" erected no doubt to afford a view, which is not so good as may be obtained near at hand from the island. Suppose this kind of "improvement" goes on, the charms of the scene must perish to a great extent. In a great country like America, where land has in many cases a merely nominal value, all such glorious scenes as this should be preserved for the public for ever. That could be easily done in this case by reserving a strip of land along the margin, so that the towns and factories would not protrude themselves so as to be reflected in the water. There is plenty of room for towns and hotels without allowing them to destroy the woods and copses that frame this glorious picture! The Government has reserved

* See p. 18, ante.

the famous Yosemite Valley for the public for ever—and a most wise proceeding it is. Nothing tends to vulgarise and entitle a scene like Niagara more than planting on its very margin a great hotel. Let such structures be near enough for convenience, or even for a good view; but not so near as to stamp out all traces of the once beautiful foreground. Besides, the hotels themselves lose considerably by being thrust, as the Clifton House is, on the margin of the river, without a tree to soften its hard outlines. All such structures would gain considerably by being cut off from the river by at least a lawn and plantation; and this need not deprive them of a good view of the scene. If we deface such rare and magnificent scenes, posterity will regard us as sordid barbarians. I never yet saw a spot which, if preserved, would in time to come form, without any but the simplest aids, so paradisaical and vast a garden, taking the river for a mile or two above and below the falls into consideration. For miles below the falls the woods are charming, and some of the scenes—as the whirlpool, where the river makes a sudden bend in its deep rocky bed—quite unique. The greatest portion of this space is as wild as ever, so that it is not yet too late to guard it from the hands of the spoiler. Nothing could be in worse taste than allowing persons to extract half-dollars from the public for the mere permission to see such places as the whirlpool. But as multitudes visit the place, the temptation to occupy every inch of land and prostitute it to some dollar-extracting use will be irresistible if the States do not step in and save it. All that needs to be done by the American and Canadian Governments is to prevent persons clearing or occupying the ground within a few hundred yards or even feet of the margin. This done—and means taken to secure the destruction of the wretched buildings that now perch themselves on the margin of the river—and, without any further attention from man, the place would ever be unrivalled in its majestic beauty—a garden worthy of America, and which, in the interest of the whole world, ought to be preserved from pollution.

THE PROPAGATOR.

HOW TO RAISE VERBENAS FROM SEED.

THAT the Verbena has been greatly improved of late years, nobody can deny; but, after all, it is doubtful if so much has been done with it in the way of cross-breeding, or fertilization, as by careful selection of certain flowers from which to take seed. Still, something has been done, evidence of which exists in the pretty striped flowers raised by Mr. Perry, of Castle Bromwich, during the past four years. These possess as many fine qualities of form, size, and substance, as the best of the self-varieties so called. Seedling Verbenas, as a rule, are not prolific of striped flowers, and fertilization appears necessary, to some extent, to produce them. Mr. Perry's aim was to obtain white flowers, having stripes of vivid scarlet or crimson, and in two fine varieties, named respectively, Carnation and Singularity, these combinations were strikingly present.

Supposing a cultivator of Verbenas has a flower possessing unusual brilliancy of colour, or some hue strikingly novel, but having the pips deficient in that circularity of form to which considerable importance is attached in these days; in order to combine the particular colouring with a higher degree of form, he would select a finely-rounded stout flower like Eckford's Peter William, or Perry's Perfection, and, using a very fine camel's hair, he would gently insert it into the tube of the flower, and transfer the pollen from it to the one from which he desires to obtain seed. In case of some flowers that are subject to the process of fertilization, it is the custom to remove, as far as possible, the pollen deposited on the anthers, replacing it with that brought from another flower, for the purpose of promoting fecundation. In the case of the Verbena, this would be a somewhat tedious, and, possibly, an injurious, process, and, therefore, it is the custom with raisers simply to transfer the pollen from one flower to the other, without any anterior removal of the pollen from the proposed seed-bearing flower.

A careful selection of seed from a few fine varieties will assuredly produce flowers of remarkable quality. For seed purposes, plant out, as early in the season as possible, on an open airy spot favourable to the proper ripening of the seed.

The seed thus obtained should be kept through the winter, and sown about the middle or end of March, in any conveniently-sized pots, using a good, free, rich loam, and covering the seeds to the depth of a quarter of an inch. The pots can then be placed in a temperature of some 65 deg. or 70 deg. and the soil kept constantly

moist. The seed germinates quickly, and in about three weeks or a month the young plants will be large enough to prick off two or three inches apart into pans, pots, or shallow boxes, and as soon as the roots lay hold in the fresh soil, begin to harden off gradually, and, as soon as it can be safely done, get the plants into a cold frame. Spider is very apt to lay hold of the young plants at this stage, and proves a bad enemy if it once gets the upper hand. Amateur raisers should guard against harm from the attacks of this pest.

Meanwhile, a bed should be prepared in the open air, for the reception of the seedlings. A rich, free soil suits the Verbena admirably. Plant out, by the beginning of May, if the plants are sufficiently large and incurved to exposure. They soon make rapid growth; and all that is required is to keep the bed free from weeds, till the plants begin to flower. Then it is the raiser selects the best of his seedlings. A short stick is usually placed against any flower worthy of attention; and the inferior varieties around it are removed, so as to secure ample room for development. It is from such flowers the seed for another season's sowing should be taken.

Let it be remembered, the Verbena likes, and, consequently, flourishes best in a rich soil. The liberal use of well-decomposed manure is employed by all successful cultivators, and the bed should be in an open situation. There is nothing like the open ground on which to test Verbenas. There is nothing more likely to interfere with their well being than coddling them in pits or houses. One of the foremost Verbena raisers of the day, Mr. H. Eckford, of Coleshill, grows all his seedling Verbenas in the open ground; and there is this great advantage about it, that it is a most favourable, and, at the same time, fitting mode of testing the habits of growth of the seedlings. A Verbena without a good free stocky habit of growth is, after all, of but little value.

R. D.

A NEW AND EXCELLENT FLOWER-POT.

WE are all apt to run short of flower-pots of one sort or other at the busy spring season of potting, and it happens sometimes that a fresh supply cannot readily be obtained; the little history, therefore of a successful makeshift which I propose to give may be as useful to some of your readers as it has proved to me. Examining some pear-grafts in the autumn of last year I found that the old fashioned mixture of clay and cow-dung which had been used in the operation had become so hard that it was necessary to employ a knife to remove it. I held this little matter in mind, and in the spring I had a good heap of clay, cow-dung, and sand well mixed together, and set some men, one wet day to the task of moulding sixty-sized small pots in a metal mould I had provided. These pots were put on dry shelves and stoke-holes, and were allowed to dry thoroughly. They were then employed for potting-off geraniums, verbenas, lobelias, irises, and other bedding plants. I had the satisfaction of seeing that the plants did well in their clay covering, and the pots bore the watering well. In

May they were plunged into the summer beds with the plants, and I calculated that the clay and cow-dung would gradually fall to pieces, would help to support the plant, and would first induce it to form a ball of roots, so that in the autumn its removal would be attended with little loss of roots. The result has been more satisfactory than I anticipated; the clay pots, in most instances, have remained entire, but the roots have pushed through the bottoms, and above the rims, and the plants come up with a compact ball, very different from others turned completely out of the pots, which have sent down long roots, half of which they lose on removal. I have had some of these pots preserved with the plants in them as they were taken up, and I am persuaded the contrivance will be of immense use, not only to me, but to others. I, therefore, send you a sketch of a plant taken up from the bed a few days ago, the lifting of which will only cause the slightest possible check to it; also a sketch of the somewhat rude iron mould, with a wooden plug to fashion the lump of clay, cow-dung, sand, &c., into shape. We tried first moulding in an ordinary flower-pot, but broke so many that we gave up terra-cotta in favour of iron.

W. INGRAM.

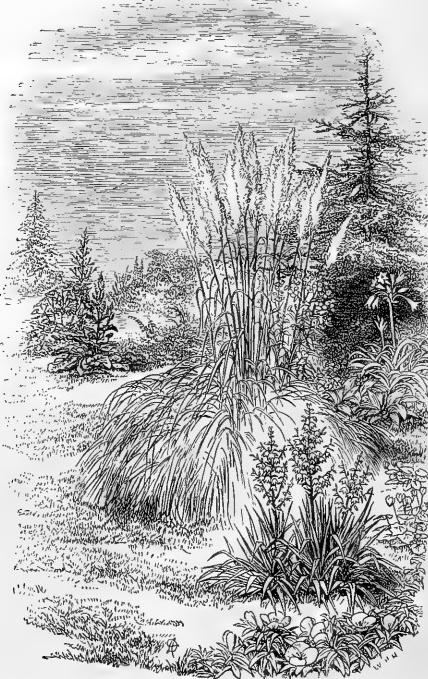

Pelargonium, Flower of Spring.

GARDEN DESIGN.

HOME LANDSCAPES..
BY NOEL HUMPHREYS.

Is the epidemic of geometric flower-gardening abating in intensity? it may be asked. No, far from it. It is still spreading far and wide, and the fair face of nearly every garden in the three kingdoms is either pimpled or pitted with the mighty and glaring patches of this garden disease. No doubt very striking effects of colour are thus achieved at very little cost of intellectual culture or judgment, and with an excessively limited knowledge of the endless variety of exquisite flowering-plants, acquaintance with which it would be necessary to study in order to carry out successfully the creation of "home landscapes," instead of geometrically-shaped and formally-placed patches of large numbers of plants of the same kind.

Geometrical gardening, upon the bedding system, has, however, not been entirely without its utility. It has stimu-

lated the culture of very beautiful plants, though of few sorts, with unvoiced activity and great success, causing old kinds to be improved, and many new and valuable varieties to be raised.

But it is high time that a general reaction should be initiated in the direction of a nobler, simpler, and more natural mode of treating our pleasure-gardens; and it is pleasant to observe that already many of our most advanced gardeners and amateurs are beginning to perceive, as Mr. Robinson points out in his instructive introduction to "The Sub-tropical Garden," "how far we have diverged from Nature's ways of displaying the beauty of vegetation; our love for mere rude colour having led us to ignore the exquisite and inexhaustible way in which plants are naturally arranged

* See p. 18, ante

in a wild state; brilliant blossoms being almost invariably relieved by a setting of abundant green."

By directing attention to this principle in the creation of a pleasure-garden, and in the more artistic distribution of flowers, shrubs, and trees in combination with the characters of the green elevations and depressions of our lawns, either natural or artificial, delightful home landscapes may be created, as lovely, or even more lovely than any real Alpine scenery; for, undoubtedly, true art may be made to aid and improve nature.

Let us imagine such a nook as that represented within the framework of the capital H. in the first number of *THE GARDEN*. How charming would such a flowery hollow be, within eyeshot of a drawing-room window! It is made to appear as a glimpse of some very highly-favoured bit of flower-land towards the end of summer, or rather the commencement of autumn. In front is a profuse tuft of the rose-tinted Japan Anemone, a handsome free-growing plant that at once gives the keynote of natural growth, free from the trammels of any kind of trimming or training. Immediately behind it is a mass of Tritoma Uvaria, with its noble heads of brilliant scarlet blossoms, shading into orange and yellow, which define themselves effectively against a mass of dark-green foliage. To the right, is a showy plant of one of the rank-growing but picturesque Rudbeckias, in front of a great towering tuft of Hollyhocks; beyond which is a bush of one of our finest flowering-shrubs, the Althaea frutex; and other attractive plants just shadow forth their forms beyond, to be fully appreciated only by a nearer approach than the glance from the drawing-room window.

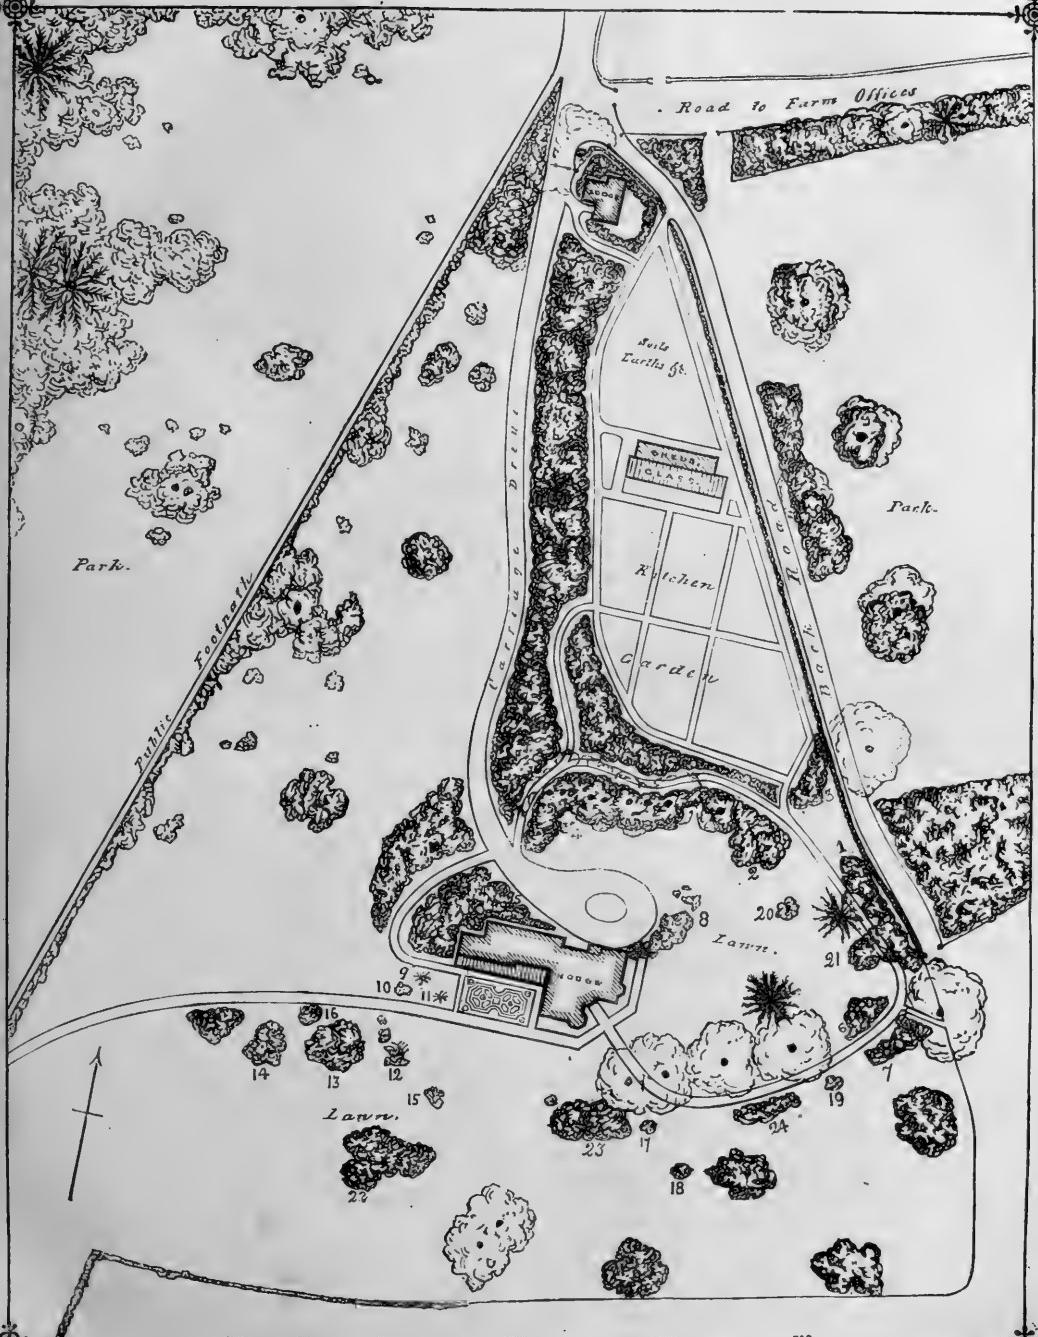

Turn now to another scene, represented in this article—a more open, and somewhat wilder piece of home landscape. How grandly the giant mass of Pampas Grass occupies the principal place in the living picture, shooting up its noble plumes to the height of some eight feet or so, near a bank on which Crinums are growing and blooming as though in their own native wilderness! How different is the aspect of the gigantic grass in such a position, from that which it is often compelled to assume in the precise centre of a circular flower-bed, surrounded by a regular double ring of Geraniums or other "bedding plants"! Call in an artist—a true student of nature—and ask him which he prefers. In front is a group of Yucca pendula in flower, the scale of which, though often reaching three feet in height, is dwarfed by the lofty height of the Pampas plumes. To the right, are scattered tufts of Cyclamen, just as they are found on the knolls and slopes of an Italian campagna. The low-growing plants in front is the Eustoma macrocarpa; and beyond, in the distance, are great detached clumps of nobler hardy herbaceous plants. Of these, the Ferulas and various others of great beauty have not as yet been introduced to gardens generally.

We shall have so much to say on home landscapes, and on good and simple methods of producing them with the greatest effect; and shall have to add so much on the score of the endless variety of flowers and trees, by which the aspects of garden landscapes may be varied *ad infinitum*, that we cannot afford space to say more in this general introduction to the subject.

BUCKLAND, THE SEAT OF F. H. BEAUMONT, ESQ.

THE almost total absence throughout the country of evidence of taste in garden design, and this nowhere more apparent than in our most famous private and public gardens, has made us determine to endeavour to remedy the evil by the publication of plans of gardens, not remarkable merely for their lavish wealth of plants, or vast extent, but for the true taste evinced in their disposition. With this aim in view, we shall often have to select comparatively small gardens for illustration, for, so far as we have observed, it is among such that the best examples of good taste are now to be found. Plans of gardens, it is well to bear in mind, however, are often very deceptive; frequently those places displaying very bad taste look well on paper. Every person interested in this matter should, therefore, understand that it is by abolishing the gyrations that often look so attractive on plans, that we get the space and breadth that characterize the true garden, and that we do not look down upon a garden as we do upon the squares of a chess-board.

With reference to the annexed plan, it may be mentioned that it represents a place of no small extent, charmingly situated near the

foot of that portion of the Surrey hills known as the North Downs, and commanding fine views both of upland country and broad sweeps of open park-land. Originally an old brick wall extended along the eastern side of the present line of carriage drive, running very nearly as far as the mansion. This has been removed, with the exception of some portions that are thickly covered with ivy, which have been allowed to remain, and which have been utilized (as all such objects should be) by being worked into the general arrangements of the place. On the opposite, or western, side, of the carriage road, an old hedge, very much of the ordinary type, existed, and this also has been cleared away with the exception of a few picturesque thorns, which have been here and there allowed to stand alone. Towards the south-eastern parts of the ground, and where the best views of the open park lands are to be found, an old farm-road occurs, and in order that the traffic along it should not be visible from the pleasure-ground, the centre of the road has been lowered where it crosses the line of sight, and the sides slightly, but almost imperceptibly, raised, but in such a manner as to fall into, and blend with, the natural surrounding ground, so that, looking from the locality of the house, the ground appears to retain its original natural aspect.

Several large old trees exist also, both on the east side of the carriage road, to the south-east of the mansion, and in other parts of the ground. These trees have been carefully preserved, and have been either worked into the new plantations, or, where they stand on grass, the surrounding ground has been so managed as to make them fall into and blend with the general scheme of improvement to which the place has been subjected.

With regard to the arrangement of planting: passing along the carriage drive, we have, on the left, the large trees already referred to, and an undergrowth added of ordinary evergreen and deciduous shrubs. With respect to the detached clumps and groups, it is only necessary to remark that they are formed in the usual way, but that each has one or more distinct and striking trees introduced into it, for the sake of variety and contrast, and at the same time for conferring on each separate group a certain individuality of its own. In the following references, therefore, these special subjects only are referred to, the remainder being ordinary plants:—

Clump No. 1.—Weeping Willow. No. 2.—Magnolia grandiflora; *Thujopsis borealis*; *Salisbury adianthoides*; *Thuja Lobbi*; *Rhus Cotinus*. No. 3.—*Lombardy poplar*; *Prunus cerasifera*; *Acacia*; *Wellingtonia gigantea*; *Cupressus Lawsoniana*; *Pinus Sylvestris*. No. 5.—*Laurus nobilis*; *Populus tremula*; *Spiraea*; *Tilia*; *baccata*; *Thujopsis borealis*; *Cryptomeria Lobbi*; *Red Cedar*; *Thuja Lobbi*; *Cedrus atlantica*; *Picea Nordmanniana*. No. 8.—*Thuja Lobbi*, No. 9.—*Pinus Cembra*. No. 10.—*Rhus Cotinus*, No. 11.—*Yucca gloriosa*. No. 12.—*Pampas Grass*. No. 13.—*Picea nobilis*. No. 14.—*Aralia japonica*. No. 15.—*Juniperus fragrans*. No. 16.—*Cephaelanthus Fortunei*. No. 17.—*Scarlet Thorn*. No. 18.—*Thuja mucronata*. No. 19.—*Cephaelanthus*. No. 20.—*Cedrus atlantica*. Nos. 21 and 22.—*Beds of Rhododendrons*. No. 23.—*Mixed Shrubs*. No. 24.—*Roses*. No. 25.—*Mixed shrubs*. No. 26.—*Mixed Shrubs and Roses*.

The Kitchen Garden has, it will be observed, been effectually shut off from the carriage-road, and also from the pleasure-grounds, by a screen of planting, combining existing large trees with other suitable ones of intermediate growth, filling in with various kinds of shrubs.

Where no special plants are named for a group, the planting would consist of such things as different kinds of Box, Holly, Laurustinus, Aucuba, Portugal Laurel, Thujas, *Thujopsis borealis*, *Cupressus Lawsoniana*, Cotoneaster, Liliacs, Spiraea, Weigela, &c.

In addition to these, there is a sprinkling of such deciduous trees as Acacia, Mountain Ash, Laburnum, Gleditschia, Thorns of various kinds, and similar things which, being of only medium size, and having small and, in most cases, pinnate foliage, do not too much overshadow the plants underneath, afford sufficient protection from extremes of weather, and tend to break up the various masses, giving them more or less a light and varied outline, thus obviating the appearance of too much sombreness of tone arising from masses of evergreens, as well as the lumpish effect which groups of mixed shrubs are likely to present where not broken up in this way. The full and easy breadth all round the house is worthy of note.

Overdoing.—It should be a cardinal rule in landscape art (as in all other art, I think) not to multiply means for producing a given effect. Where one stroke of the brush is enough, two evidence weakness, three incompetency. If you can secure a graceful sweep to your approach-road by one curve, two are an impertinence. If a clump of half-a-dozen trees will effect the needful diversion of the eye, and produce the desired shade, any additions are worse than needless. If some old lichenized rock upon your lawn is grateful to the view, do not weaken the effect by multiplying rocks. Simple effects are the purest and best effects, as well in landscape art as in moral teaching. A single outlying boulder will often illustrate by contrast the smoothness of a lawn better than a ponderous roller. One or two clumps of alders along the side of a brooklet will designate its course more effectively and pleasantly than if you were to plant either bank with willows. A single spiral tree in a coppice will be enough to bring out all the beauty of a hundred round-topped ones.

Because some simple rustic gate has a charming effect at one point of your grounds, do not for that reason repeat it in another. Because the Virginia creeper makes a beautiful autumn show, clambering into the tops of one of your tall cedars with its five-lobed crimson leaves, do not therefore plant it at the foot of all your cedars. Because at some special point the red rooflet of a gateway lights up charmingly the green of your lawn, and fastens the eye of visitors, do not for that reason make all your gateways with red rooflets. If some far-away spire of a country church comes through some forest vista to your eye, do not perplex yourself by cutting forest pathways to other spires.—D. G. MITCHELL.

PUBLIC GARDENS.

PARIS GARDENS AND PARKS.

I HAVE just returned from a tour around the various public-gardens here, and beg to send you a few words of information as to their present condition. The Park Monceux has not suffered much. In fact, little in it has been destroyed by the siege or by the Commune. The only difference is shown in the ornamentation. Instead of beautiful-foliated and flowered plants, which were much admired formerly, and which were the delight of lovers of horticulture, I noticed but a few species of *Pelargonium*, *Ageratum*, *Chrysanthemum*, &c., not better than those to be seen in a London shop-keeper's garden. The small squares, like la Tour, St Jacques, la Temple, la Champs Elysées, have received no alteration in their forms, and they have preserved their old aspect, except the change in the quality of the floral decorations. At the Square des Invalides, the gardener, who has been recently appointed to replace M. Troupeau, principal gardener of the squares in the interior of Paris, has absurdly replaced the pretty ivy-borders by lines of dwarf box-tree. Since MM. Barillet and André resigned their situations of head-gardeners, a sort of interim had taken place up to the last spring. The engineer-in-chief, M. Alphand, who had the general superintendence of this service, having been raised to a higher position, the promenades and plantations have been placed in the hands of an engineer, M. Darcel, des Ponts et Chaussées, who knows nothing about gardening. So the fair days of public gardening in Paris are past.

However, an improvement has taken place lately. A M. Rafarin, who had charge of the propagating gardens and houses of La Muette, where all plants required for public gardening were cultivated, having carelessly left, everything to perish by the winter frost, has been removed, and replaced by M. Troupeau. We have just seen this last-named gentleman at La Muette, and we are happy to say that the collections will be soon restored in his hands, perhaps not to their former state, but still to good order.

At the Avenue de l'Impératrice, which had been entirely spoiled—with all the trees, conifers, evergreens, and rare shrubs, cut down and burnt—an army of gardeners is now at work. Unfortunately, the arboretum that had been planted there with so much care and skill will not be replaced. The Empérator was opposed to roadways through these gardens from place to place, so as to allow people to cross the avenue; therefore they were obliged to walk a long way without an opportunity of getting across. To-day this inconvenient arrangement is done away with. All necessary thoroughfares have been provided, and instead of the high iron-fences along the lawn edges, some elegant arched rustic-iron borders have been placed as a frame to the garden. They have improved the mode of sloping the ground, and are making what they call *vallonnements*, by undulating the surface of the lawns and planting clumps of trees on a larger and more harmonious scale. Some evergreens will be planted there; and the new plantations of Poplars, Horse-chestnuts, Ash-trees, &c., already made, without showing much at once, will be effective in a few years.

The Bois de Boulogne has not now the sad aspect it presented when we saw it last March. Almost all these dreadful-looking and empty places that we noticed on our way at that time to the ruins of St. Cloud are now covered with fresh vegetation. The underwood, formed by new branches sprouting from the roots, will be stronger than ever in a few years; and, had we not to regret the destruction of the large forest trees, firs, pines, and rare ornamental shrubs and trees, we should find that a nicer growth is the result of the thickets having been cut down. A most curious effect is produced by the scarlet tint of the American oaks (*Quercus coccinea* and *Q. rubra*), which, of course, have been cut to the very root, like the common species. About la Mare d'Auteuil, where M. de Sabine, the *ancien conservateur* of the Bois de Boulogne, had planted several thousands of these trees, sent direct to him from the United States by André Michaux, nothing is more striking than this field of fresh branches with their scarlet foliage. All the way round, the Bois is deprived of its beautiful plantations. You notice here and there

some scattered and uninjured poor oaks or birches and common conifers. Along the formerly woody places of the Bois they have constructed a line of wooden fence, to prevent people from walking into the thickets and destroying the new vegetation.

The Porte-Dauphine entrance of the Bois, by the Avenue de l'Impératrice, is to-day almost entirely repaired, replanted on each side as it was before; and, in the course of a few months, no trace of the gigantic barricades and fortifications, cheveux-de-frise, &c., will remain.

The houses of La Muette, much more injured by the shells of the Commune than by the siege, have not much improved since the last time I saw the place. The new range of houses situated in the Clos Georges, between the railway and the Rue de la Tour, is still quite empty, the glass in pieces, and the pits inside the houses covered with weeds. The prospect of desolation has now ceased here. Some collections remain perfect, as the Camellias, Azaleas, and a few others; but I saw with much regret all those beautiful palms black and dead in their boxes. I shall soon have another opportunity of completing these notes on the present state of gardens and gardening in Paris and in France, which, I hope, will recover shortly from such tremendous disasters.

Paris, Oct. 22, 1871.

E*****

THE IN-DOOR GARDEN.

PALMS FOR THE GARDEN.

THE word "palm" suggests to many a majestic tree towering above all others, and, therefore, we at once conclude that palms are unfit for anything but a large house. Though this is true of such kinds as Sabal umbraulifera, Arenga saccharifera, and a few others; yet if we take into account such miniatures of them as Arcea monostachya, Chamaerops humilis, Rhapis flabelliformis, and others, which show their beauty at the height of from three to six feet, we at once discover that not only are they suitable for small conservatories, but that they are also useful as ornaments for the window or table; having, moreover, the advantage of lasting the whole season, thereby making up for the difference of cost in the first instance as compared with that of other plants. On the Continent palms sell by the thousands for window decoration, at low prices, and I hope, now that they are becoming appreciated here, we shall soon see them selling at a price within the reach of all. Another advantage palms possess over other plants for decorative purposes is the hardness of their foliage, which, in some measure, saves them from injury from gas and changes of temperature, and renders them capable of being washed when dusty without fear of breakage; again, they are not liable to be hurt by over-watering, which kills so many plants of other kinds. As to diversity of foliage, we have fan-shaped leaves in the Latanias and Chamaerops, pinnate in Areca, Thrinax, Cocos, and others; while with the beautiful Adiantum-like foliage of Caryotas and Arengas everybody is charmed; in fact, no conservatory or stove can be said to be complete without palms. Let me, therefore, hope that, by giving some account of the habit, country, and nature of such sorts as are best adapted for general purposes, I may be instrumental in encouraging the cultivation of this beautiful class of plants.

As regards soil: that which suits them best is loam, with slight drainage, as the roots, being strong, run to the bottom of the pots, and form drains, as it were, themselves. Though some palms are found in dry places, it is well known in districts where they grow naturally that wherever there is a palm, water is sure to be below it, from which the roots, running as they do deep, derive a good supply. So thirsty, indeed, are palms generally that they may be watered every day with advantage, and, if in a stove, they enjoy a pan to stand in during summer-time.

In potting, the roots should never be cut or pulled out; and if the plant can be placed lower in its new pot, all the better, as it encourages the production of fresh roots. Spring is the best time to shift the greenhouse kinds, but stove palms may be re-potted at any season, water being given freely immediately after the operation, both at the roots and in the form of a good syringing.

In the following descriptions, habit and the decorative uses of each sort will be the points chiefly dwelt upon. The flowers of many are not likely to be seen, excepting those of a few Chamadorias, and therefore it is useless to speak of them. I may remark, however, that, many palms being unisexual, those who want to do anything in the way of hybridization must procure male and female plants of Chamadorias, in order to effect their object; and that seed, when obtained, should be sown in a bottom heat of from 80 degs., to 90 degs. I shall briefly refer to each genus, taking the species alphabetically, so that my list may be consulted with facility, and enable those requiring one, twelve, or fifty kinds, to get the best for their

respective purposes, limiting my observations to such sorts as are in cultivation, and giving their synonyms:—

Arcea alba (Mauritius).—A fine palm, bearing from eight to ten fronds, eight feet long, of a greyish green; stem clear. A fine plant, when old, to stand above others, the fronds standing almost flat from the stem; in a young state they are more erect; this species may be distinguished by a filament running from leaflet to leaflet when first developed; the leaflets in all Areccas are flat, and nearly opposite. A good sized palm in all stages of growth; suitable for table decoration.

A. Baueri (syn., *Seaforthia robusta*; Norfolk Island).—Plant denser in habit than the last; fronds more erect; midrib clothed with black scales; leaflets, in young plants, four inches wide. A good greenhouse palm, or for out-door decoration in summer, and in a large state one of the noblest of its class, its dark-green foliage contrasting well with Musas, Latanias, and Caladiums.

A. crinita (syn., *Calamus dealbata*, *Acanthophoenix crinita*; Mauritius).—A very elegant palm, having the appearance of a Calamus; useful for standing over a tank, having, when six feet high, fronds four feet long, of a drooping habit; being dense, it is unfit for table decoration; upper side of fronds green, underneath white; the petiole and stem densely clothed with light-brown spines; rather tender, and requiring plenty of water.

A. Catechu (East Indies).—The palm that produces the betel-nut; in a young state, good for table decoration; habit erect, running up with a slight stem; foliage bright green, quite smooth and glossy, contrasting well with that of other palms; a fast grower when placed in a smart heat, which it enjoys.

A. concinna, (East Indies).—Allied to the former in habit, but dwarfer, and a slow grower.

A. latifolia (syn., *Hyophorbe indica*; Mauritius).—One of the best of palms for table decoration and for stoves, being small and dwarf, and forming offsets as it gets old; fronds graceful, pale green; petiole with a yellowish tinge, in the centre of which the whole plant partakes a colour that varies in intensity in different individuals. Young plants of this species may be kept in small pots for two to three years, if copiously watered. This is a palm which should be in every stove, as it is well adapted for mixing with large-leaved plants, and, being erect, it stands well above them without intercepting light.

J. C.

THE IN-DOOR GARDEN FOR DECEMBER.

BY THOMAS BAINES, SOUTHGATE.

A CALENDAR, I need not say, acts as a sort of prompter, to assist the memory of the practical gardener, who, under the pressure of multitudinous duties, is apt to forget the performance of some operation at the proper time; and if it emanates from cultivators who have been careful observers—who have, in fact, made it their study to pick up these cultural crumbs, which lie thickly on the ground for those who have the perception and industry to gather them; and who have had, moreover, more than usual experience in the departments of which they take charge—then it will, perhaps, not be presumptuous to suppose that these instructions may be of use to those even who already possess a practical knowledge of horticulture. Our limits only admit of a portion of the things which require attention during every season of the year being touched upon, therefore we shall confine ourselves to such as we have found to be of most general use. As regards my own particular department I may premise that I have no startling cultural revelations to make by which success can be attained under all or any circumstances, but only a number of small matters attention to which I have found essential to successful cultivation.

Stove.—Now is the best time to eradicate insect-pests, as both foliage and wood ought to be in a condition to bear a stronger application of whichever of the numerous insecticides is used than when growth is active. Whatever is applied for this purpose, ought to be persevered with until no insects are to be found; this will necessitate repeated applications, for it is little better than labour lost to kill the greater portion and still have a breeding stock, that will cause no end of labour in spring, when it is required in so many other channels. Let all glass and woodwork, both inside and out, be well scrubbed and washed with clean water; if only for the sake of preservation, it is as good as a coat of paint; but it effects an object of still greater importance, viz., the admission of every possible ray of light, of which, in our sunless winters, we are so deficient. Place all plants as near the glass as possible, for although there is now comparatively little growth, still, light is essential to their general health. Clear out all old tan, and refill with new. I do not, however, advocate plunging in tan by any means; on the contrary, I never plunge a single plant, for the object the production of flowers for cutting, or of plants for the decoration of cooler

structures; in either case it renders them soft and liable to flag. But a good tan bed will maintain a temperature of 90 degs. for many weeks; a circumstance which materially helps to keep up the necessary warmth of the house without resorting to so much fire-heat. On this account alone the use of tan is wise economy, leaving out of the question the healthy atmosphere which it promotes.

There is scarcely a garden, large or small, now to be met with in which the demand for cut flowers is not at least double what it used to be. Therefore we must grow such things as last longest in a cut state, and grow them, too, under such conditions as will assist that property. For instance, the beautiful *Euphorbia Jacquiniflora*, as often grown, flags in a few hours after being cut; but if small plants of it are grown, say in six or eight-inch pots, so as to admit of their being placed within two or three inches from the glass, their blossoms will stand when cut for a week; and this holds good of almost every other plant, but especially of that most useful of winter subjects, the old white *Azalca*. This requires very little heat to induce it to bloom, provided that in its growth and the setting of its flowers there has been a little forethought as to the time at which they would be required. Place, in gentle heat, now, plants of *Deutzia*, *Spiraea japonica*, and *Lily of the Valley*, along with such *Hyacinths*, *Narcissus*, and other bulbs as are likely to be required. Get *Allamandas*, *Bougainvillas*, and *Clerodendrons* sufficiently dry at the roots to induce them to shed their leaves and to get into a state of rest. Be careful not to place bulbs of *Caladiums* or *Gloxinias* in too low a temperature; 50 degs. for *Gloxinias* at rest, and 60 degs. for *Caladiums*, will keep them right. To name any fixed temperature at which stoves should be kept, would be a mistake, inasmuch as each individual should be guided by his requirements, and, above all, by the condition which his plants may be in; always remembering that those that have made and matured their growth under those essential conditions,—abundance of light, and sufficient air, with plenty of healthy roots, will stand a higher degree of temperature without excitement, or a lower one with impunity, than weak, half-ripened plants will, that are deficient in stamina.

Orchid House.—The growth of most of the East Indian orchids ought to be nearly completed, and therefore they will require a reduction as regards temperature and moisture, both at the roots and in the atmosphere. It is, however, a bad practice to dry them up indiscriminately to the extent often done, with a view to induce a greater profusion of bloom. Most of the *Dendrobiums* require to be well dried, otherwise they do not flower freely; but *Vandas*, *Saccellabiums*, and *Aérides* are frequently dried to an extent that causes them to lose their bottom leaves, thereby spoiling their appearance; and this is wholly unnecessary, for if their growth is made under sufficient light and air, with an absence of too much heat and moisture they will show bloom at every leaf they make. I feel confident that three-fourths of the "spot" that yearly destroys such numbers of these valuable plants is produced through too much heat and moisture, with too little air and light; true, they frequently bear up against ill-treatment of this kind, even for years, for orchids will bear more bad treatment than most other plants, but ultimately they give way under it. *Cologynne cristata*, which is one of the most beautiful as well as useful of winter flowering plants, should never be allowed to become dry at the root, or be in too dry an atmosphere; but at this time, when it is throwing up its flower-spikes, see that they do not get much wet in the operation of watering, or they will damp. From 60 degs. to 65 degs. night temperature will be sufficient during the season of rest.

Most of the plants in the Mexican house should now be at rest, and with the exception of *Lyceaste Skinneri*, *Odontoglossums*, and plants of similar requirements, they should receive little water for the next two or three months, only just sufficient to keep them from shrivelling too much. The beautiful *Cattleya Skinneri* ought now to be put in the coolest end of the East-Indian house, as it will not stand so low a temperature as most of the other inmates of the Mexican house, the night temperature of which may now range from 48 degs. to 55 degs. We frequently find a collection of orchids from both eastern and western hemispheres grown in the same house, and with better results than where the treatment is of that extreme character either as to heat or cold that some growers adopt.

Greenhouses.—Be careful here in watering all hard-wooded subjects. Never water before a plant really wants it, and never defer the operation for an hour after it does require it. Get all specimen plants tied, using just sufficient and no more supports in the shape of sticks than the nature of the plant requires. Now is a good time to wash all *Azaleas* with moderately strong tobacco-water, laying the plants down over a shallow trough, so as not to waste the liquid; after which lay them on their sides until dry. By no means wash the liquid off, as is sometimes done; for although no living thrips may be seen, still their eggs may exist under the little black spots on the leaves, ready for hatching under the genial influences of a higher temperature; these the tobacco-water will kill. I have found

this much better than smoking, which, when done strongly enough to kill the insects, generally causes some of the leaves to fall prematurely off; and all the smoke possible will not kill the eggs. Sulphur is the best antidote for mildew, should that pest make its appearance; but be careful that it does not get into the soil, for its effects there on the roots of plants are similar to those of lime. If *Primulas* have had the attention which they deserve, the first batch will now be strong plants coming fast into bloom, therefore assist them with occasional applications of clear liquid manure. Give them all the light possible and a dry atmosphere, and if they can have a night temperature of 45 degs. they will not be liable to damp. The first batch of *Cinerarias* will be throwing up their blooms fast; these will be equally benefited by liberal applications of manure-water; but instead of being on dry shelves like the *Primulas*, they should be accommodated with a cool, moist bottom of ashes or sand. *Calceolarias* for spring blooming require similar treatment. *Cyclamen*s will be benefitted by a little more heat than that usually given to ordinary greenhouse stock. Place them near the glass, or the blooms will come weak. *Camellias* required for flowering about Christmas will now be opening apace, if their treatment during the season of growth has been such as to induce a disposition to flower at this time; but it frequently happens that they have to submit to more heat at this time to get them into blossom than they like, and unless some judgment is exercised, they will cast their buds. This is often attributed to a bad state of the roots; but no matter how good their roots are, even with sufficient moisture in the soil, if the atmosphere is too dry, the buds will drop; therefore it is necessary, where heat is required to induce them to open, to keep sufficient moisture in the atmosphere to prevent this happening. The conservatory should now be kept at about 45 degs. night temperature, and every effort should be made, by means of tasteful arrangement, and in other ways, to render it as engaging as possible, more especially at this season, when the attractions of the out-door garden are at a minimum. Towards the end of the month put in cuttings of *Chrysanthemums* where large blooms are required; for cutting, early struck plants will be found best. On wet days get a good stock of plant-stakes made and painted, also tallows; and let crocks be washed and broken; let, too, all spare pots be washed ready for use. See that the different soils required for potting are got under cover, so as to be sufficiently dry for use when wanted. If severe weather sets in during the month, be cautious not to use more fire-heat than is necessary, as any excitement to plants now is most injurious.

ASPECTS OF VEGETATION IN NORTHERN AND TEMPERATE COUNTRIES.

HERBACEOUS VEGETATION IN SIBERIA.

AMONG the many aspects of vegetation in northern and temperate countries, few are more singular than that of the great cow-parsnips and other plants of the Umbelliferous Order, with tall grasses, nettles, &c., which abound in Siberia. So rapid and vigorous is the growth of these in early summer that it would seem as if the giant herbaceous plants, fated to hide beneath the ground every year, had resolved to rival trees in stature during the short summer life of their stems. In spring huge earth-buds followed by noble young leaves; in summer a herbaceous forest; in autumn the tall stems, through which the sap coursed so vigorously in spring; dead and dry, the strongest of them yet rigid and erect, a miniature blighted forest, while the promise of another year lies in the great buds swelling just beneath the surface. There they rest till the relentless winter is gone. This is one of the many interesting types of northern vegetation that we may readily develop in our pleasure-grounds and woods. It would indeed be out of place in the garden proper, but in nearly all country-seats there are various spots on islands, on the banks of streams or ponds, or in rich and sunny hollows in woods or copses, or the rougher parts of pleasure-grounds, where the giant type of herbaceous plants might be grown without any trouble, and with a striking and picturesque effect. It need hardly be remarked that this type should not be included in what is called "dressed ground," as half the beauty of such an arrangement as that proposed would consist in its absolute wildness; and the stately dead stems should be left to the care of the snows and rains of winter. In collecting suitable subjects for planting, it would not be desirable to select plants from Siberia alone, as we have but a few of its giant herbaceous plants in cultivation. All herbaceous plants of large and vigorous habit and noble port

ASPECTS OF VEGETATION IN NORTHERN AND TEMPERATE COUNTRIES.—HERBACEOUS VEGETATION IN SIBERIA.

should be selected. They would require no attention whatever after planting. All the following will thrive well in ordinary soils, and are obtainable in this country in nurseries where collections of herbaceous plants are grown. Of some, like the Verbascums and Onopordon, seed, may be sown on the spot. *Callisœus dahuricus*; *Arundo Donax*; *Crambe cordifolia*; different varieties of *Ferula*; *Gynerium argenteum*; various kinds of *Hælianthus* and *Heracleum*; *Polygonum cuspidatum*; different sorts of *Onopordon* and *Rheum*; *Datisca cannabina*; *Phytolacca decandra*; *Silphium in var.*; *Eupatorium purpureum*; *Vernonia noveboracensis*; *Aralia*, various herbaceous kinds; *Asparagus Broussonetii*; *Asclepias Cornuta*; *Centaurea babylonica*; *Bupleurum speciosum*; *Gunnera scabra*; *Lavatera unguiculata*; *Altheas*; *Papaver bracteatum*; *Cynara Scolymus*; *Verbascum in var.*

W. R.

THE FRUIT GARDEN.

FRUIT-TREES FOR ORNAMENT.

It is often thought that Nature is usually sparse of leaf-beauty where the flower is highly ornamental, and stings with flowers where leaves assume large proportions and elegant outlines; and, to a smaller extent, that she is apt to exhaust herself in an analogous way upon fruit. Nothing can be further from the fact than this supposition. When we consider the flowering charms of the greater portion of our fruit-trees, we are struck with astonishment that they are not more planted for the sake of their beauty alone. Take the apple in its countless varieties, and just consider that, if it did not give such crops of fruit, beautiful to look upon, and more delicious in flavour than half the boasted fruits of the tropics, we should seek after it for the sake of its blushing cups, which turn the formal orchard into a scene of fairyland.

But it happens to bear fruit of various colours, sizes, and flavours, and, of course, that is a reason why we have hitherto not employed such a beautiful hardy tree in the pleasure-garden. Then we have the pear, which comes in earlier, and furnishes snowy masses of bloom; and with a more picturesque and handsome habit than the apple, but unhappily with the same fault of bearing delicious as well as ornamental fruit.

From nearly every hardy fruit we may reap a like harvest of beauty—almonds, apricots, cherries, crabs, medlars, peaches, plums, and quinces, being all more or less ornamental. And some of them have not even the merit of fruiting—the double cherries and double peaches, for example. Both of these trees should be planted ten times more abundantly than they are at present, for no trees are more attractive. There is a scarlet variety of the double peach, which imparts a vividness of colouring to the shrubbery in early spring that we have hitherto been quite devoid of; and there are others deeply coloured, as well as a pure white one, all of which deserve to be extensively employed. And as perhaps some curious persons here and there may not object to plant beautiful flowering fruit-trees because they also bear precious and handsome fruit, a few observations on the best way of enjoying them may not be out of place here. We have sought to do but place these objects, usually hidden in the orchard, in any open spots, in pleasure-grounds, by wood walks, in the fences at intervals, instead of the worthless stuff that now too often occupies them—and, in word, in the many positions where many trees neither good for timber nor flowers now take up valuable ground.

There is another phase of the question to which our readers are probably strangers, and that is the ornamental orchard. We have never seen it attempted but once, and that was in the garden at Meudon, where it was very successful. Usually the orchard is, of all spots, the most formal; but there is no need that it should be so, as anyone with extensive pleasure-grounds can quickly prove. At Meudon the position was a sort of valley-like hollow, but in an elevated position—just the spot to make a concise pinetum or pleasure-ground. Instead of planting it with trees and shrubs of the ordinary type, it was resolved to embellish it with well-arranged groups of fruit-trees. On one side a large clump was devoted to handsome pyramidal pear-trees, on another one to apples, another to plums, and so on. The grass was not broken up, nor any of the ornamental features of the spot interfered with in the least. We need hardly point out how varied, as well as exceedingly useful, such an arrangement might be made. There might be mixed groups of new and untried kinds, as well as masses of thoroughly appreciated ones; there might be isolated specimens of various kinds on the grass, from an apple on the dwarf Paradise stock to a fully-grown and handsome pear of twenty-five or thirty feet high. Fruits little

known or of doubtful utility like the *Eugenia* or the cherry plum, might be associated with the others with greater propriety than in the fruit-garden proper. Such things as the American blackberries—and very fine some of these are—would find a congenial home; so would the dewberry and the various cranberries, which some like so much. The relatives of our common fruit-trees might of course be planted in the near neighbourhood for comparison's sake; standard peaches, figs, and apricots, might be tried with safety if the garden were in the south; and the whole would prove one of the most interesting features in a country place.

THE FRUIT-GARDEN FOR DECEMBER.

BY WILLIAM TILLERY, WELBECK.

Out-Door Fruits.—Hardy fruit-trees of all kinds should be planted as early in the month as possible. If not done in October and November, the pruning of fruit-trees should likewise be carried on with vigour. In neglected orchards this is an operation of great importance; for the trees get so crowded with wood and spurs, that good crops are few and far between. Were orchard-trees carefully pruned every year, and the fruit thinned where too thickly set, failing crops would seldom be seen, and the fruit would be of the largest and finest quality. This is now a good time to eradicate that pest to apple-trees, American blight. I had some cordons and dessert varieties of apples on an east wall very much infested by it last year, and stamped it out, in the winter-time, by scrubbing every branch where it appeared with a hard brush, then painting the places over with soft soap. The system of growing single and double cordons of apples and pears on the bottoms of walls and trellises will be found of great utility, and a source of enjoyment to the cultivator. They are not recommended to take the place of pyramids or bush fruit in the borders, but only to fill up bare places on the bottoms of walls where nothing else is grown, and as edgings to the sides of walks, where they interfere with no other crop in the borders. This year, I have had very fine fruit off single cordons of Calville Blanc, Reinette du Canada, Reinette Grise, Herefordshire Pearmain, Menagere (a large French apple), Belle Dubois (another very large French apple, like Warner's King), Calville Sauvage, and some other kinds of apples and pears. The apples are all on the French Paradise stock, and the fruit is thinned out, so as to leave only a dozen or two on each tree, according to the size of the sort. These little trees, being grown on the bottom of south and west walls, do not suffer much when in blossom from spring frosts, being sheltered by the foliage above them. Single and double cordons, however, planted as edgings in the border are more exposed; but they can be easily protected from spring frosts by means of a few fir branches or light straw hurdles. When these cordon trees are planted in December, a covering of litter over the roots will keep the winter's frost out, and keep the roots moist in dry springs.

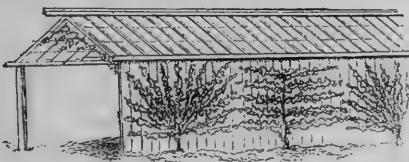

Figs on the walls will soon want protection from severe frosts in winter, and when the branches are tied together, and straw wrapped round them, they will be quite safe. Where dried fern can be had, it likewise makes a safe covering, by thatching the trees with it. Gooseberries, currants, and raspberries, may be still planted; but, at this late period, it is better to mulch the roots afterwards. A way to get rid of gooseberry caterpillar on established bushes infested by them is to scrape away all the earth from the base of the bushes, and dig it into the middle of the rows. The space denuded round the bushes, if filled up with old tan or fresh soil, will contain no larva or young caterpillars to crawl up the stems, and commence their ravages in the summer. Strawberry-beds are often top-dressed in December with litter, to protect them from severe frosts; but experience makes me recommend this operation to be deferred till the spring. When the beds are top-dressed, then, with some rather strawy litter, just before the spring-growth commences, the foliage and fruit stalks grow through it, and the fruit is kept clean from heavy rains; besides, the litter keeps the roots of the plants moist in hot, dry summers. The nailing of wall-trees should now progress as fast as possible in open weather; for it is cold work in the dead of winter, and in spring many other operations occur which cannot be deferred. The nails should only be driven in sufficiently to hold, and never into the bricks to injure them; for it is foolish work spoiling good walls with nails, when wiring them would answer every purpose; and all new walls should be done so. The fruit stored in the fruit-room will now frequently want looking over, and all fruit picked out that show the slightest symptoms of decay. The temperature should be kept rather low, and as equable as possible; and all damp and frosts expelled by artificial heat. All vines artificially forced are liable to much injury by severe frosts in the winter, if left in the open air. They should, therefore, be protected till they are taken into the forcing-houses.

In-Door Fruits.—As early forcing generally commences in this dull and dreary month, vines, when breaking, will require a temperature of from 55 degs. to 60 degs., with air given freely in favourable weather. Grapes in late vineyards will require frequent looking over, in order to pick out any decaying berries, as they induce damp, which infects the others. Where such houses are wanted for any particular purpose, the grapes, if cut off and put into bottles of water, will keep good for three or four months in a well-ventilated fruit-room, or other room fitted up for the purpose. Early peaches started this month will require a temperature of from 40 degs. to 45 degs. at night, and admit plenty of air when that is possible. When in blossom, the pollen should be gently distributed with a feather, in order to assist the fruit to set. The earliest batch of strawberries will now want introducing into a forcing-pit, or placing on the shelves of a peach-house at work. If a little bottom heat in a pit heated by oak, or any other kind of leaves, can be used, with the temperature of the pit kept low and well regulated, the fruit will set all the better. I find Keen's seedling and President best for the earliest supply. Figs, in pots, may now be started where an early supply is desired; and any requiring shifting, or top-dressing, should now be looked to, using turfy soil of a loamy nature with a little leaf soil, and plenty of drainage. Orchard-house trees of all kinds should be pruned as soon as the leaves drop, and top-dressed, if not done in October or November; a solution of Gishurst compound, consisting of about five ounces to a gallon of boiling water will, if put on when cold, by syringing the trees, be an effectual cure for insects. Peach-trees trained on walls will likewise be much benefitted by the same application, if put on with a powerful syringe or engine.

Pine-Apples, now swelling their fruit in various stages, should not have too much heat while the days are dark and short, nor too much humidity. Those starting now into fruit should be placed in a compartment by themselves, where they can be kept pretty dry while in bloom, or abortion, or some deficiency in shape of pips, or uneven swelling, will most likely be the result. Succession plants in all stages should be kept in a growing state, moderating the heat and humidity to suit the season. Give air freely when the weather is favourable, surrounding the pits with fermenting materials to their summits, in order to heat the interior and dispel damp. J. B.

FOSTER'S APRICOT SHED.

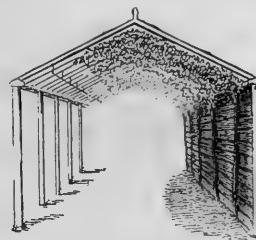

MR. FOSTER, of Beeston, has, I think, by chance hit on the best known plan of growing apricots. Requiring a shed to back carts under, and to shelter ladders, planks of oak, &c., he thought, as it would be seen from his garden, that a glass roof would look much better than one covered with slate. He accordingly built one about one hundred feet long and ten feet wide. Posts every nine feet carry the roof, which is all fixed, no ventilation being required. The south-west side, next the garden, is boarded and painted over with tar, wired, and planted with dwarf-fruit-trees, as in the woodcut. Wires are also stretched under the glass, as if for vines; the distance from the glass being about one foot. On the north-east side of the wooden fence, standard

Apricot Shed.

apricots, plums, and nectarines are planted, whose heads are trained under the glass, their roots passing under the wooden side into the same border in which those shown growing on the outside are planted. Both ends of the shed are closed in with boards. It is, in fact, a long narrow glass shed open to the north-east, just high enough to back a cart under, but looking from the garden like a double-roofed greenhouse. The trees have been planted three years; they have never been syringed, and, in fact, except tying the shoots to the wires and thinning and gathering the fruit, have had hardly any attention. In some parts of the shed it has been necessary to climb over piles of timber from four to five feet high to get a good look at the fruit. The result has been extraordinary and, to me, most unexpected.

The nectarines have not been large, but high coloured, and of good flavour; but it is evident that these would be better for more heat. Plums would have been all that could be wished if it had not been for the plum aphis, but as these have been allowed to have their own way, the trees have suffered from their attacks. Apricots seem to have found all they require, and look quite at home. The foliage, though untouched by rain or syringe, is healthy, large, and free from insects or mildew. The first year they were planted they bore a good crop. The last two years almost every blossom appears to have set. I counted, before they were thinned, seventeen apricots on a shoot seven inches long; and each season they have carried twice the number of fruit I would have allowed to remain for a crop. In spite of the large crop, the fruit was beautiful in colour and most delicious, and I have seldom seen so fine a

Section of Apricot Shed.

sample. I should say the trees have been only watered twice since they were planted, and that in the hot summer of 1870. Though I think few would have foreseen such a success through what may be considered an accidental discovery, it cannot be thought the less valuable on that account. How loudly it proclaims the advantage of ventilation for apricots! Does it not equally proclaim, too, the advantage of a dry climate for this tree? What method of pruning apricots can compare with this, either for productiveness or cost of production? The trees are sheltered from frost and wet, and the roots take care of themselves. How different from either the open wall or the orchard-house! No watering, no syringing, no shading! Even good gardeners have been surprised at the result.

Chilwell.

J. R. PEARSON.

THE HOUSEHOLD.

SELECT EDIBLE FUNGI.

BOLETUS EDULIS.

BELIEVING it desirable that the more useful edible fungi that abound in our woods and pleasure-grounds should be much better known than they now are, we propose to publish, from time to time, descriptions of the more important species, with the most improved modes of cooking them; accompanied by drawings and engravings by Mr. W. G. Smith, who knows these subjects so well and draws them so faithfully and so gracefully.

Boletus edulis is one of the safest and most delicious, and at the same time most abundant and long-continuing, of the British edible fungi. The first crop may be gathered soon after the rains of early summer, and the growth continues till the frosts of winter have fairly set in. There are about three dozen species of Boletus in this country, but B. edulis materially differs from all its allies; it is probable that most Boleti are either edible or harmless, but such species as B. edulis and B. mstivalis certainly stand in the first rank. Our plant has maintained a good reputation from time immemorial, and has been consumed as a delicacy in all countries of Europe for ages; not, however, in this country; but, thanks to Dr. Badham, Dr. Bull, and others, it is at last rapidly becoming a recognised article of diet with us.

To distinguish this plant from other Boleti, the following points must be carefully noted, and when the fungus is once known, no other species will ever be mistaken for it:—It grows in woods; the cap is smooth, and of a very pure and delicate shade of pale brown, often with an edge of a lighter shade, as shown in our illustration; the under surface of the top, instead of being furnished with gills, like the mushroom, has a soft spongy substance, composed of innumerable

pores or tubes (like the pipes of a miniature organ); this spongy substance is at first pure white, then sulphur-coloured, at length sulphury-green; the stem is stout and fleshy, pale brown in colour, and furnished with an exquisite minute reticulation or network round the upper portion; the flesh, when broken, is snow-white, like crumbs of bread, and the taste agreeable and nutty. It should not be gathered for the table when too young, when the tubes are white; or when too old, when the tubes are green and the plant flabby; neither should specimens be used that are mildewed or soddened with rain. They are in the best condition when the tubes are sulphur-yellow. *B. edulis* grows to a great size, being often many inches across; it is frequently very irregular and uncouth in shape, with a swollen stem; and at times varies considerably in the colour of its cushion-shaped top, which, at times, will vary from delicate fawn to

Boletus Edulis (Edible Boletus); Woods; Summer and Autumn; delicate fawn colour; tubes yellowish; diameter 4 to 12 inches; spores enlarged, 700 diameters.

brown. One of its best points of distinction resides in the beautiful white network round the apex of the stem.

The following is Paulet's recipe for *Boletus edulis* soup, as made in Hungary:—Having dried the *Boleti* in an oven, soak them in tepid water, thickening with toasted bread, till the whole be of the consistence of a puree; then rub through a sieve; throw in the *Boleti*, boil together, and add with the following Person:—One pound of butter, and a pint of this sauce for the table in the following manner:—It may be cooked in white sauce, with or without chicken in fricassee; broiled or baked, with butter, salad-oil, pepper, salt, chopped herbs, and bread crumbs; to which may be added some ham or a mince of anchovy. It makes excellent fritters. Some roast it with onions (basting with butter), but as the onions take longer to cook, they must be put down first, and when they have begun to brown, lay the *Boleti* over them.

Mr. Wm. Linn, the veteran botanist of Worcester, writes as follows of this species:—It should not be disguised with any sauce, beyond lemon-juice and powdered lump-sugar; for, as part of a fungus dinner, it should come last with the puddings and sweets. As a fritter or sweet omelette it is excellent; and when thus delicately cooked, it has a close resemblance to custard-pudding.

Dr. Bull, of Hereford, has published the following recipe for *Boletus edulis*:—*P' Andalucia*.—Take the stems and pores, wash them, and divide the remainder into half-moon slices. Take six or eight ounces of lean uncoocked mutton, cut into small squares, and put them into a large steeppan, add a large wineglass of the best salad-oil, and fry for a few minutes, until the ham takes a pale yellowish colour, then add the pieces of *Boleti*, and fry for another five minutes; remove from the fire, and add a teaspoonful of chopped parsley; add a large wineglassful of sherry. Then place it on the fire, with the lid of the stepppan, and let it stand for three or four minutes; then add a little water; stir in the juice of half a lemon, and serve it hot. (B.—The ham has a warm, aromatic flavour, but is not hot to the taste. If it cannot be procured, a fresh green Chili may be substituted; or, the dish will be excellent if the judicious cook will slightly increase the quantities of the other condiments. A very good and simple plan of cooking, is merely to remove the tubes and stem, and cut the top into slices, and fry with butter, &c., like the common mushroom; or lay the pieces in a dish, with butter, pepper, and salt; cover the dish close, and bake for half an hour.)

A few species of *Boleti* are either highly-coloured, acrid when raw, or change to bright blue when cut or broken. Such as these, and all having the tube surface red, should be discarded. W. G. S.

American housewife is no longer at the mercy of the season. The delicious summer pear, which decays soon after it is ripe, is not now merely enjoyed during the few weeks of its perfection; the housewife collects her fine Bartletts (Williams's Bon Chretien) in good time, peels them, and by a very simple process preserves them. And in mid-winter, when the snow is deep round the house, the pears are as good as in September. But if one kind of pear will not keep, others will for a long time, so, perhaps, the utility of the system is not seen in this case so much as in that of perishable fruits. Then take the tomato, so indispensable in every American house. It is much cheaper than the potato during the summer and autumn months; but before the epoch of canned fruit there was a long and dreary interval dreaded, by the lover of tomatoes; now they are obtainable all the year round. And so of every other esteemed fruit or vegetable, from peaches to asparagus and green Indian-corn, with the exception of the apple, of which there are varieties that keep so long as to ensure a supply till the current year's fruit is ripe, and thus remove any necessity for canning. This process is now so well known and practised there that most housewives can their own fruit. The table in every house shows its value, and whole villages and towns are sometimes devoted to the preservation of one article for the market.

The vessels in which fruits are preserved are tin, glass, and earthenware. Tin is used at the factories where large quantities are put up for commerce, but is seldom used in families, as more skill in soldering is required than most persons possess. Besides, the tins are not generally safe to use more than once. Glass is the preferable material, as it is readily cleaned, and allows the interior to be frequently inspected. Any kind of bottle or jar that has a mouth wide enough to admit the fruit, and that can be securely stoppered positively air-tight—which is much closer than water-tight—will answer. Jars of various patterns and patents are made for the purpose, and are sold at the crockery and grocery stores. These have wide mouths, and a glass or metallic cap which is made to fit very tightly by an india-rubber ring between the metal and the glass. The devices for these caps are numerous, and much ingenuity is displayed in inventing them.

Mason's jars are very commonly in use in America, and nothing can exceed their simplicity and excellence—a wide-mouthed glass jar, with a ring-band of india-rubber on its neck; on this the edge of the zinc screw cap rests. This cap is very simple, and can be readily screwed home. A little vertical bar on the outside of the cap gives a hold to a small wrench, formed so as partially to grasp the neck of the jar, enabling anybody to screw air-tight or open the jar in an instant. When such excellent contrivances as this are popular, it is needless to allude to the practicable but past method of using cement and corks. We shall give in due time the best American modes of preserving the various kinds of fruits, vegetables, &c., as the system deserves to be popular everywhere fruits and vegetables are grown.

Mason's Fruit-jar.

THE ARBORETUM.

THE SWEET CHESTNUT.

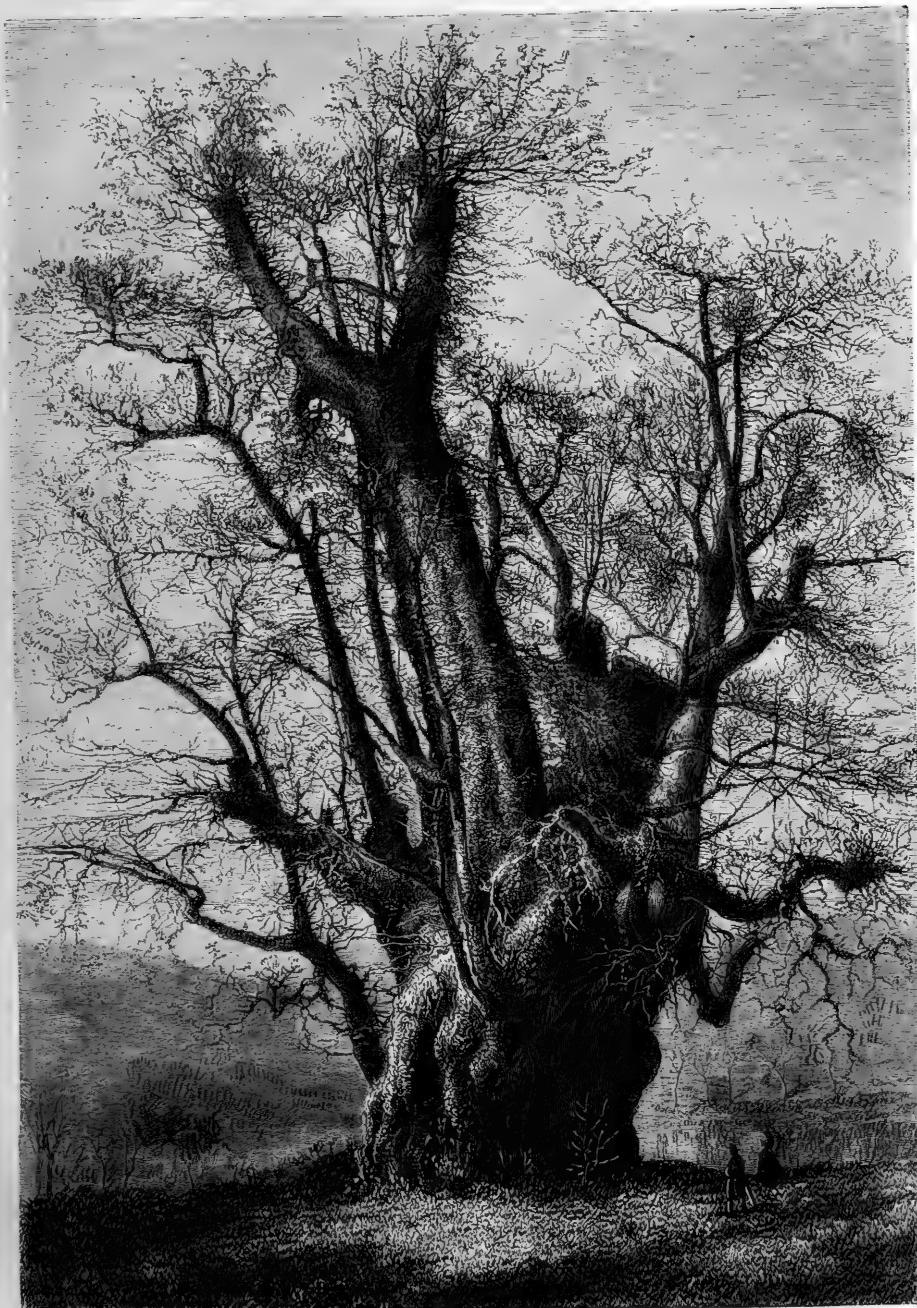

MOUNT Etna is celebrated for the great age and colossal dimensions of its chestnut trees; for one of the largest and oldest trees of the kind in the world is that on Mount Etna, which is called Castagno di Cento Cavalli. It is said Jeanne d'Alragon on her road from Spain to Naples, visited Mount Etna, attended by her principal nobility, and being caught in a heavy shower, she and a hundred cavaliers took refuge under the branches of this tree, which completely sheltered them.

A century ago, according to Brydon, this tree measured 204 feet in circumference near the ground; but more recent travellers give only 180 feet as its girth. There are also two other celebrated chestnuts on Mount Etna, one called the Castagno di Santa Agata, which measures 70 feet in girth; and the other, Castagno della Nave, which measures 64 feet; their stems, however, attain no great height, but soon branch off above the ground. According to Dr. Philippi, the *Castanea vesca* does not appear to be wild on any part of Mount Etna, but always to be cultivated.

In Britain, the sweet chestnut is by some considered to be indigenous; but, notwithstanding the great age of some specimens, it appears more than probable that it was introduced into England by the

AMERICAN FRUIT-PRESERVING JAR.

There is one practice in common use in America which for us is almost as important as if we could command a brighter climate for one division of our farms and gardens—we allude to the practice of "canning" fruit. This means the preservation, in a perfectly palatable and wholesome state, of fruits and vegetables for any needful length of time in tins, or more commonly in glass jars. The

OLD CHESTNUT-TREE ON MOUNT ETNA (180 FEET IN CIRCUMFERENCE).

Romans. The largest tree in England of the sweet chestnut, is said to be one at Croft Castle, in Herefordshire, which, thirty years ago, measured 80 feet in height, with a stem 8 feet 6 inches in diameter, and the spread of its branches 112 feet. The great Tortworth chestnut, on Lord Ducie's estate in Gloucestershire, measures 57 feet in circumference, and is mentioned by Sir Robert Atkins, in his history of that county, as a famous tree in King John's time; and by Evelyn, in his "Sylva," to have been so remarkable for its magnitude in the reign of King Stephen (1135), as then to be called the Great Chestnut of Tortworth; from which it may reasonably be presumed to have stood before the Conquest (1066).

The sweet chestnut is found in the east and west of Asia, and north of Africa, and in Asia Minor, Armenia, and the Caucasus. It is generally said to have been first brought to Europe by the Greeks, from Sardis, in Asia Minor, about 504 B.C.

The chestnut is displayed to most advantage when standing singly or in scattered groups along with our oak. Gilpin considers the chestnut in maturity and perfection as a noble tree, which grows not unlike the oak; its ramifications, however, are more straggling, but free, and its foliage loose. As an ornamental tree the chestnut ought to be placed before the oak; its beautiful leaves, which are never attacked by insects, and hang on the trees till very late in the autumn, mass better than those of the oak and give more shade. An old chestnut standing alone, and especially when in flower, is a noble object. In old trees the bark is remarkable for its deep, wide clefts, spirally directed, which give to the stem the appearance of being twisted.

The chestnut, however, should never be planted near a residence, because the flowers emit a very powerful and disagreeable odour, which is offensive to most people. A group of chestnuts forms an excellent background to other trees; but a chestnut copse is insupportably monotonous. The sweet chestnut prefers a deep, sandy loam; it will not thrive in stiff, tenacious soil; and in a rich loam, its timber, and even its poles and hoops, are brittle, and good for nothing.

In Britain the tree will not attain any height unless in sheltered situations, and where the soil is free and of some depth. While in poor, gravelly soil, where its roots will only run along the surface, it will attain a very considerable diameter of trunk and be of great longevity, though its head may never be larger than that of a pollard; of this the chestnut trees in Greenwich Park and Kensington Gardens, near the magazine, may be cited as examples; but wherever the chestnut is planted in good and warm soil, and in a warm and sheltered situation, it will outgrow any other tree in the same length of time; perhaps, the larch, the willow, and some poplars excepted. The chestnut, also, thrives well among rocks, where there is apparently very little soil, insinuating its roots among the fissures and clefts.

The wood of the chestnut has the remarkable property of being more durable when it is young than when it is old, the sap or outer wood very soon changing into heart-wood; and hence the great value of this tree for posts, hop-poles, stakes, hoops, &c. - In every part of the country where hops are grown, the most durable poles are found to be those of the chestnut.

GEORGE GORDON, A.L.S.

PINUS PONDEROSA.

I AM a great admirer of this tree. It forms one of a splendid group of ternate pines (three leaves in a sheath), having for its companions *P. Benthamiana*, *P. Jeffreyi*, and *P. macrocarpa* (*alias* Coulteri). All are from California, and have many points of resemblance. Unfortunately, they all agree also in being peculiarly liable to the attacks of that most destructive and tantalizing beetle, the *Hylurgus piniperda*, which (some years more than others) effects a lodgment into, and totally destroys, the leading shoots. It is very aggravating to find at a fine robust shoot, which yesterday was developing its leaves, suddenly drooping, and, on examining it, to see the medullary central pith eaten up by the larva of this troublesome insect. You vindictively and indignantly destroy the wretched grub; but, alas! it is too late. The work of destruction is complete, and the growth of the year is arrested. All the splendid pines just named are perfectly hardy with me; and the *P. ponderosa* bears the reputation of being a very rapid grower. Probably, when well-established and in luxuriant growth, it may bid defiance to the onslaught of the noxious pest alluded to; but its introduction (in 1826) has been too recent to afford us well-matured and full-grown specimens. From what I have seen of them I expect that the *P. ponderosa* will become a splendid tree, both in point of ornament and utility. It should, when fully grown, form a magnificent

object; and its timber must indeed be solid, close-grained, and tough, if it be true (as is reported, and implied in its name) that it is so heavy as to sink in water.—A. MONGREDIEN.

The *Pinus ponderosa* here, measuring from the ground, is seventy feet in height; the circumference at one foot up is nine feet four inches, and at four feet from the ground it is eight feet; one third of the circumference being the nearest approximate diameter.—JOHN COX, Redleaf.

I have measured our largest specimen of *Pinus ponderosa*, and find it to be twenty-six feet six inches in height, and three feet ten inches in circumference one foot from the ground.—WM. M. BAILLIE, Beaumont Castle.

P. ponderosa does not grow well in the north of Scotland. Its top gets heavy, and its roots do not spread very much on the surface, and it generally loses its upright position, and falls over. This has been the fate of all those that I have known to be put out singly, and at present I do not know of a *P. ponderosa*, forty feet, remaining in this quarter. It appears hardy enough, and planted in suitable soil closely, in clumps, it might be able to hold on and stand straight; but I know of no such clump in this district, and here the tree is not in demand, as it generally falls over before attaining the height of thirty feet when alone.—JOHN GRIGOR, Forres.

SEASIDE TREES AND SHRUBS.

A few facts respecting such trees, shrubs, and other things as will grow, thrive, and stand before all others the blast and violence of the great storms that repeatedly visit our coasts, may not, perhaps, be uninteresting. I mean such as do really thrive, and are always green, even under the violent storms that in spring-time and autumn so suddenly take place, and drive a long way inland the thick spray of salt water, killing and scorching up foliage, young shoots, and branches of almost every kind of tree, shrub, and flower in its course. Many kinds of vegetables, and even our native weeds, pasture-grasses, &c., are forced to yield before such devastating storms from the south-east as occurred on the 10th, 26th, and 27th of September last. Having within these three years visited all the Channel Islands, Scilly Islands, Isle of Wight, &c., and having travelled all round the coast from thence to Land's End, besides taking a look at other coasts, I am able to state precisely what really does stand out fresh and green, while other trees and shrubs similarly circumstanced are burnt and scorched up.

Prominent among those which bear the sea blasts are the following:—*Euonymus europaeus* and its variegated varieties, *E. latifolius*, *americanus*, and *atropurpureus*; *Virginia Creeper*; ivy—always cheerful and fresh-looking; *Laurustinus*, *Spartium junceum*, common myrtle, and *Myrtus mucronata*.

It is truly wonderful what storms and sea washings myrtle will stand, and afterwards look fresh. As to the *Escallonia macrantha*, it is the very best of all seaside plants; I mean that it will grow and thrive in any kind of soil, close to the sea, in every place and aspect. Even after great storms it exhibits a most lovely, shining, healthy green colour, when its neighbours are all scorched up; and it is always in bloom, if the strong shoots are stopped or pinched out. It is, moreover, one of our best evergreens for making a quick, thick, and beautiful hedge for garden shelter I have ever yet met with. Its beautiful green, glaucous foliage, and warm red flowers, make it a plant of great value. *E. rubra* and *E. montevidensis* are also lovely varieties, which stand the sea breeze well. The old *Rosmarinus officinalis* also grows to an immense size close to the sea, and will stand any amount of breeze and salt-water spray. This would likewise make very quickly splendid hedges of any height or width, close to the sea, for breaking the force of those terrible storms that damage everything else subjected to them; besides, on account of its perfume, it has a value for distilling purposes. I really, therefore, wonder it is not more planted than it is. The *Arbutus Unedo* and its variety, *rubra*, are both glorious seaside plants, which are always green and beautiful every day in the year; and now, after the successive great storms and drenchings of salt spray which they have had, they are covered with beautiful scarlet-coloured fruit,

green fruit, and blossom. Indeed, *Arbutus laurifolia*, magnifica, and some others, are all good and flourishing seaside plants. The Phillyrea family again furnishes some of our most useful thriving evergreen shrubs for seaside planting, standing even unscathed great and sudden storms of wind and sea spray. I have noticed that *Phillyrea media*, *angustifolia*, *rosmarinifolia*, *ligustrifolia*, *pendula*, *oleifolia*, *latifolia*, *levis*, *obliqua*, *virgata*, and *spinososa*, all withstand great violence without a scorched shoot or leaf. That pretty, delicate sub-evergreen plant, the *Tamarix gallica*, is well known to all seaside visitors, growing and thriving as it does everywhere, even on high-dry rocks, on the sea shore, in the salt sand, salt marshes, and low swampy places, maintaining a luxuriance that is surprising, without the least ill effects from any sea gale. With a little care in the way of management, this might be induced to make fine hedges for shelter. The *Baccharis halimifolia*, which grows freely, will likewise be found to make hedges of any width and height for seaside shelter; even when planted on any dry, rocky, sandy, salt, poor soil, it thrives most luxuriantly, and stands, even close to the sea, any amount of sea breeze and spray. The *Barberry*, *Box Thorn*, or *Duke of Argyll's Tea-tree*, grow most luxuriantly, even when close to the sea—the last, particularly, will grow in nothing else but a bank of saline sand, where every high tide swamps it, and every breeze blows on it, "suckering" and spreading immensely; a rare plant to retain and fix any extent of blowing, loose sand, and for sheltering and nursing others for planting to reclaim waste and useless sand. *Pinus pinaster* and *austriaca* grow everywhere close to the seaside, and stand the breeze and spray well at all seasons. They make capital nurses for sheltering other plants. But among the whole of the plants to be found thriving close to the sea, everywhere the *Cupressus macrocarpa* stands pre-eminent. This is truly the most valuable of all seaside conifers, growing so luxuriantly that, planted to any required extent, it would very quickly afford excellent shelter for any seaside bleak place in a very few years, breaking and softening the most severe gales into a soft breeze, and altering the harshness of the climate in a way most desirable in bleak localities. This truly handsome cypress, too, seems to thrive and grow with luxuriance on every kind of soil.

I may add that every kind of pink, carnation, and picotee, thrives wonderfully well all round the sea-coast, on any kind of soil, even when subjected to the very splash of sea water.

JAMES BARNES.

TREES.

I WANT you to understand, in the first place, that I have most intense, passionate fondness for trees in general, and have had several romantic attachments to certain trees in particular. Now, if you expect me to hold forth in a "scientific" way about my tree-loves—to talk, for instance, of the *Ulmus americana*, and describe the ciliated edges of its samara, and all that—you are an asperine individual, and I must refer you to a dull friend who will discourse to you of such matters. What should you think of a lover who should describe the idol of his heart in the language of science, thus:—Class, Mammalia; Order, Primates; Genus, Homo; Species, Europeus; Variety, Brown; Individual, *Ana Eliza*; Dental Formula,

$$\begin{array}{ccccccc} 2 & - & 2 & \mid & 1 & - & 1 \\ & \mid & & \mid & & \mid & \\ i & - & c & - & p & - & m \\ 2 & - & 2 & \mid & 1 & - & 1 \\ & & & & 2 & - & 2 \\ & & & & 3 & - & 3 \end{array} \text{, and so on?}$$

No, my friends, I shall speak of trees as we see them, love them, adore them in the fields, where they are alive, holding their green sun-shades over our heads, talking to us with their hundred thousand whispering tongues, looking down on us with that sweet meekness which belongs to huge but limited organisms—which one sees in the brown eyes of oxen, but most in the patient posture, the out-stretched arms, and the heavy drooping robes of these vast beings endowed with life, but not with soul—which outgrow us and outlive us, but stand helpless—poor things!—while Nature dressed and undresses them, like so many full-sized but under-witted children. . . .

Just think of applying the Linnaean system to an elm! Who cares how many stamens or pistils that little brown flower, which comes out before the leaf, may have to classify it by? What we want is the meaning, the character, the expression of a tree, as a kind, and as an individual.

OLIVER WENDELL HOLMES.

THE GARDEN IN THE HOUSE.

ARCHE upon DINNER-TABLES.

Some will say that these obscure or interrupt the view across the table, and interfere with conversation and sociability; but objections such as these have no foundation in fact. Others again may complain that they cannot be arranged without making holes through the table. But in this they are mistaken; for if each end of the wire which forms the arch be twisted into a flat coil, and the flower-pots (containing the climbing plants) be placed one upon each coiled end, the arch will be quite firm, if it be made of wire of proper strength. Arches may next be charged with being troublesome. I know full well that no really good effect in dinner-table decoration can be produced without trouble; but, speaking for myself and for some amateur friends who occasionally join me in a revel amongst floral decorations, we all consider that when suitable plants are to be procured, we get more "value" for our time in an arch than in any other kind of decoration.

The accompanying engraving is from some sketches of a very pretty arch, which was arranged in the following manner:—Upon the wire were fastened single blooms and pairs of blooms of *Lapageria rosea*, which had been previously mounted upon wires, so that they might stand out firmly, and hang as if they formed part of a growing plant. Three or four long branches of that beautiful climber, *Myrsiphyllum asparagoides*, were then twined over the arch from one end to the other; its bright apple-green leaves having a very cheerful effect; while they also concealed the ironmongery of the arch and the *Lapagerias*. The finishing stroke was effected by very loosely intertwining some long fronds of the commonest, but, at the same time, the most elegant of all the climbing ferns, *Lycopodium japonicum*, a species generally sold under the wrong name of *L. scandens*. In this case, the plants of these climbers were in flower-pots concealed under the table, and so also were the pots of the two plants of *Lomatia* which are seen rising from the bases of the arch. If it had not been practicable to put any pots through the table, the pots containing the two climbers could just as easily have been placed upon the table, and concealed with some common fern fronds; in which case, the *Lomatias* could not have been used, unless by cutting them down, and sticking them into the pots of the climbers—though an equally good effect might be obtained by sticking in one or two small fronds of *Pteris tremula*, or large fronds of one of the many varieties of *Pteris serrulata*.

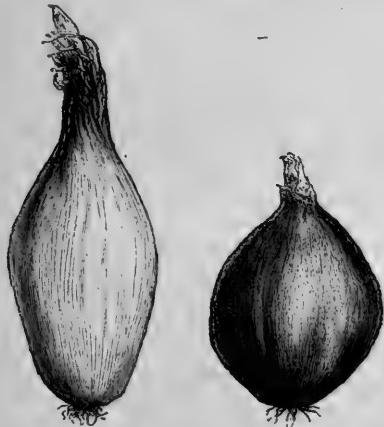

The table upon which this arch was placed was oval-shaped, suitable for a party of twelve. The plant sunk in the middle of the table was *Yucca aloifolia variegata*, amongst the lower leaves of which were inserted some fronds of *Gleichenia splendens*.

The People's Garden Company.—The first annual soirée and ball in connection with this company was held at the Royal Albert Hall, under the presidency of Sir B. J. Johnston, M.P. The suite of rooms connected with the hall was handsomely decorated with flowers and plants. The object of the promoters is to provide spaces where the people can have healthful and rational recreation, combined with instruction, under the superintendence of the members themselves, apart from those objectionable features to be found in some of the existing public gardens. The garden near Willesden was opened last season, and, though in an incomplete state from want of funds, it proved a success so far as the experiment had gone.

THE KITCHEN GARDEN.

THE TRUE AND THE COMMON SHALLOT.

Few persons, I fear, will share my enthusiasm in investigating Alliaceous matters; in fact, I know that the whole onion tribe—in common with not a few other commendable things—is not by any means in good odour with the many. But I shall, at all events, have one reader who will be interested in the subject—an Irish baronet, who has such a high respect for every form of the onion tribe that his standard of ability in a gardener is his power of producing as great a variety as possible of these delicious esculents every day in the year. The cook may be furious for other edibles, and the fair sex pine for flowers, but the gardener is always safe from the combined attacks of the household if he is good at the onion tribe. I now merely touch upon this subject—one which would require the pen and feeling of a Brillat-Savarin to do it justice—to point out that there are two distinct kinds of plants grown as shallots, and that the true shallot is becoming replaced by a plant distinct as a species, and distinct physiologically. Our most trustworthy gardening books speak of the shallots as varieties of one species. Thompson says, "Much dependence, however, cannot be placed in these varieties, for they are all extremely liable to degenerate in two or three years to the common sort." The fact is, however, that the now "common" shallot is entirely distinct from the true shallot. The true shallot (*Allium ascalonicum*, fig. 1, is, as the name indicates, a native of Palestine. It has round and hollow leaves in close tufts, and rather long conical bulbs growing close together, the outer tunic or skin being of a dull grey, and not shining. It flowers rarely, on a cylindrical naked stem; the flowers are reddish, with long segments, and closely set in a globular terminal umbel, somewhat like those of the chive. It is of a milder and more delicate flavour than the false or common shallot.

1. The True Shallot, natural size. 2. The Common Shallot, natural size.

The common shallot (*A. cepiforme*) cannot be traced to any known country as its native home. It grows in tufts somewhat like the true shallot, but has its leaves inflated at the base, and the bulbs are roundish, and usually little more than half the length of those of the other, of a light chestnut colour, and shining. The flowers of this are white, just like the common onion, but smaller, with longer stamens, and the alternate stamens usually without the lateral cusps that they possess in the common onion, but sometimes there are lateral cusps. Both plants are perfectly easy of cultivation in England; but the common one is the hardest of the two, and keeps a little longer. The bulbs, as I write this (January 15th), of the common kind are as firm and plump as those of well-ripened tulips; those of the true shallot are, in most cases, somewhat shrivelled and inclined to bud, indicating that it should be planted rather earlier than the other. I am half inclined to think that the common shallot is but a small breed of the common onion, particularly as we know nothing of its early history and native place. It is desirable to give the true shallot a warmer soil and position than the common one requires. I lately tried to procure in Covent Garden some of the true shallot for Mr. Boswell Syme, author of the new

edition of "English Botany," and had some difficulty in finding it. To me it seems most unfortunate that an important member of this most precious family—the very one on which we could most depend to confute the slanderous persons who continually revile everything in the shape of an Allium—is in danger of being exterminated in an age when such matters do not receive the attention they deserve. Oh, lovers of this interesting family—*seu pisces, seu porrum et carpe triculas*—I appeal to you to assist in rescuing from imminent extinction this precious treasure, which, having been in our midst doubtless since the days when Richard of the Lion Heart defeated the mighty Saladin before the walls of Ascalon, now seems in danger of being utterly lost to us for want of a little timely protection.

P.S.—Those to whom this appeal is not made in vain will be glad to learn that efforts are being made to form an Allium Society. A part of the plan is the issue of a monthly journal devoted to the proceedings of the society, and to the use, abuse, defence, and history of this culminated tribe—on the whole, perhaps one of the greatest blessings that Providence has bestowed on the cold and bleak fields and plains of northern climes.—"Field."

THE KITCHEN-GARDEN FOR DECEMBER.

BY JAMES BARNES, FATE OF HUXTON.

ASPARAGUS.—Take well-prepared strong roots of this and place them on a slight bottom heat, with a few inches of soil underneath them. Cover them slightly the first week, but afterwards put three or four inches of healthy light soil, decayed tan, leaf-mould, or sea-sand over them, watering to settle all down amongst the roots. Where sea-weed and sea-sand are at command, dress asparagus beds with them; but where these cannot be had, cover with good manure incorporated with salt.

GLOBE ARTICHOKES.—If these are not already protected about their crowns with litter, fern, or dry leaves, see to the matter without further delay. Also mulch Jerusalem artichokes, for they are much better taken up as wanted for use, than when taken all up at once and stored; and if mulched they can be procured daily without trouble.

BEANS.—Plant these on warm banks or borders. I like best to put some seed into a box or inside a cold frame, intermediate house, or warm corner, and to transplant in open weather in January or February; this plan not only ensures short-jointed prolificness, but the beans are also out of the reach of mice.

CABBAGE OR COLEWORTS.—If intended for winter consumption, they should all be collected into close-sheltered quarters, and laid in thickly, in order that they may be protected if necessary. Under such conditions they can also be easily found after a heavy snowfall.

CARDOONS.—Finish binding up these, and protect them with dry litter or fern.

CELERY.—All that has made its full growth, earth up finally when the weather is dry, and have at hand some protecting materials, such as litter, fern, dry leaves, or evergreen boughs, in case of frost.

CARROTS.—Those sown in July and August on borders, intended to be drawn young for use through the winter, surround with a few short stakes and tree-prunings, or with any materials conceivable, to give shelter. Sow the early horn and Dutch on a slight bottom heat, in rows a foot apart; and sow a row of radishes between, consisting of short tops, early scarlet, or French breakfast.

CAULIFLOWERS.—If there are any stay-late-autumn planted ones about, collect them together, and lay them in frames, pits, or homemade turf-pits, to be covered with thatched frames, evergreen boughs, &c.; but see that they are not devoured by mice or rats, which are apt to nibble bits out of the very best white-hearted ones. Give air to young plants placed in winter quarters, and keep them clean and dry during these short days.

CHICORY.—Take this up, and blanch it in succession, as required.

CHERVIL.—Shelter and protect a little bit for winter use.

CURLED AND AMERICAN CRESS.—Protect a small piece of each of these for daily use; and sow common cress and mustard in succession, in a gentle heat.

ENDIVE AND LETTUCE.—Such as are in store for winter use, blanch as required; keep growing crops clean and healthy, by means of frequent surface stirrings and dry dustings with wood ashes. Young late-sown lettuce, now of course small and close to the glass, as they should be, must be well attended to in the way of giving air and dry dustings, or they will mildew and damp off.

MUSHROOMS.—For these keep up a moderate humid heat of from 50 degs. to 60 degs. Beds covered with litter must be often looked over, and have the litter turned, or the spawn will soon run out and exhaust itself. Trap woodlice, and prepare materials for succession beds.

SEAKALE.—Continue to place strong-crowned roots of this in frames, pits, cellars, mushroom-houses, under staircases, or in any quiet, warm, dark corner. They must be kept dark, however, or the new kale will be bitter and bad in colour.

RHUBARB.—Take up strong roots of some early variety of this, and place them in any kind of shed, stable, cow-house, cellar, or cave. Nothing will bear more hardship than rhubarb, or produce better or more grateful crops of wholesome stalks, even under difficulties; some should also be protected and covered out of doors with old tea-chests, pots, or boxes.

ONIONS.—Dust with dry wood-ashes those for winter use and spring planting, on dry days, in order to keep them sound between wind and water, and to prevent frost from heaving them out of the ground. Old onions should be kept dry and cold, and those in store should be looked over, and kept clean and free from runaways and decay.

PARSLEY.—This should be kept clean, surface stirred, and dusted with common dry dust and chimney-soot round its crowns; it should also have a temporary fence, about a foot high, placed round a portion of it, covering it at night with thatched frames made of light materials or light hurdles, or green boughs, in order to keep frost from injuring it, and to know where it can be readily got at in the event of a heavy snow fall.

PEAS.—Sow these in the middle of the month, if the ground will admit of it, on a warm border, ridged or banked, to face the southwest, so as to escape the glare of the morning sun and to receive the benefit of his last evenings rays. Any favourite, rather dwarf-growing early variety, such as Maclean's *Advancer*, Sutton's *Ring-leader*, Sangster's No. 1, Essex *Rival*, &c., will answer. I do not approve of sowing peas in November, they are subject to so many casualties during winter after being up, such as depredations from birds, slugs, and mice. They are also liable to be knocked about by cutting winds, and to be injured by severe frosts. Sow just to get them peeping through the earth by New Year's-day, and then protect them by dredging in the evenings, when dry, with dry dust. Sow also about Christmas, on strips of turf placed in a cold viney, peach-house, pit, or frame, in order to have even crops to plant out at the end of January or beginning of February. These are sure to do well, and to pay for any little trouble in the way of dusting and shelter which may be bestowed on them. A few evergreen boughs placed behind them, will both shade and shelter them,

STRAW MATS.—Have plenty of these in readiness; also thatched frames and hurdles, in case of emergencies.

POTATOES.—Some early sort should now be put in to sprout on some slight hot-bed, such as the front of asparagus forcing-pits, or frames, intermediate houses, &c., for transplanting next month on slight hot-beds.

RADISHES.—Sow these now freely on a slight bottom heat; also on well-sheltered borders, to be covered with litter. Sow a pinch of lettuce-seed with them, and if in drills, sow alternate rows of early carrots with them; the same protection will answer for both, and both crops agree in growth and time of removing.

WOOD ASHES.—Dry wood-ashes should always be kept in store, in old tubs, boxes, &c., for dredging young lettuce, cauliflower, or any thing else subject to canker or mildew, which many things are, during the short, dark days of winter. Nothing that I know of is so effective as dry wood-ashes for preventing such evils,—but they must be dry. They answer, too, as a fertilizer for mostly every kind of plant.

TRENCHING.—Every bit of spare ground, and that which can at all be cleared from crops, should now be trenched; casting the soil up into rough ridges for frost to pulverize it. Take advantage of dry and frosty mornings for wheeling out manures, composts, and for turning the same where necessary. Look to drains, and to the repairing and turning of walks, and, in short, anything in that way that can be done advantageously at this season of the year.

NEW PLANTS.

NERINE PUDICA.—This beautiful addition to this useful and elegant class of winter-flowering Cape bulbs was introduced in 1868 from Grahamstown; it flowered the following year, and a figure of it has been published in the *Botanical Magazine* this season. The flowers, which are more compact than those of the other species, are produced, five and six in number, in pendent heads; they are rose-striped on a white ground—quite a new feature in the genus; scape, a foot high; leaves, narrow and glaucous. The plant, which is a free grower, may be kept in a frame in summer; and in winter, after flowering, it should be ripened off as thoroughly as possible by means of free exposure to light. It should be re-potted before it starts, if necessary, otherwise the seldomler this class of bulbs is shifted the better.

YUCCA TRECULEANA.—A noble Mexican plant, with erect, channelled leaves; it is allied to *Y. canaliculata* (*syn.*, *concava*), but the leaves are narrower and more erect, giving the plant a nobler general appearance than that species; where a plant is required for a vase in a windy situation, *Y. treculeana* will be found invaluable. Though known on the Continent, it is new to us. There is, however, a fine specimen of it in the collection of W. B. Kellock, Esq., Stamford Hill. It requires some slight protection in winter.

TINNEA AETHIOPICA (African Violet).—Lovers of a perfume that is said of violets will be glad of this plant for their stoves; it is a free grower, of a soft, shrubby character, resembling common Privet; its leaves are bright green; and the flowers, which are produced in their axils, are dark purple, and strongly violet-scented, especially in the evening. It will succeed in a greenhouse-temperature in summer, but it should be placed in the stove in winter, when it will flower freely. Though not a particularly striking plant, yet its perfume makes it desirable. It is a native of tropical Africa.

EURIKLES CUNNINGHAMI.—This winter-flowering bulb, from North Australia, though not really new, is, nevertheless, not often found in cultivation; its leaves are of a glossy green colour, borne upon a long stalk; the flowers, which are white, an inch in width and campanulate, are produced on a scape similar to that which exists in Eucharis. While in a growing state it is fond of water, and it should never be allowed at any time to get quite dried off, or it will start again into growth badly. Those who want plants to furnish flowers for buttonholes should try this, as its blossoms are as pure white as those of Eucharis, and of a better size for such purposes. J. C.

THE TOWN-GARDEN.

THE GARDEN ON THE ROOF.

BEFORE entering into details as to the mode of enjoying this, the most charming and novel kind of town-garden, let us quote Mr. Charles Reade, in the *Pall Mall Gazette*, on that which must prevent thousands of our readers from forming gardens on modern roofs:

"The conical roof in a modern house is not merely silly, it is disgraceful to the human mind; it was all very well before gutters and pipes were invented: it was well designed to shoot off the water by the overlapping caves: but now we run our water off by our gutters and pipes, and the roof merely feeds them; the conical roof feeds them too fast, and is a main cause of overflows. But there are many other objections to conical roofs, especially in streets and rows:—1st. The conical roof in a modern house is not merely silly, it is disgraceful to the human mind; it was all very well before gutters and pipes were invented: it was well designed to shoot off the water by the overlapping caves: but now we run our water off by our gutters and pipes, and the roof merely feeds them; the conical roof feeds them too fast, and is a main cause of overflows. But there are many other objections to conical roofs, especially in streets and rows:—1st. The conical roof, by blocking up the air, necessitates high stacks of chimneys, which are expensive and dangerous. 2nd. The conical roof passes laterally against the walls, which these precious builders make thinner the higher they raise them, and subjects the whole structure to danger. 3rd. It robs the family of a whole floor, and gives it to cats and sparrows. I say that a five-story house with a conical roof is a five-story house, and with a flat roof is a six-story house. 4th. It robs the poor Cockney of his country view. It is astonishing how much of the country can be seen from the roofs of most London streets. A poor fellow who works all day in a hole might smoke his evening pipe and see a wide tract of verdure—but the builders have denied him that; they build the roof for cats, and, the 'curse of families,' they do not build it for men whose bread they eat. 5th. It robs poor families of their drying-ground. 6th. This idiotic blunder, slightly aided by a subsidiary blunder or two, murders householders and their families wholesale, destroys them by the most terrible of all deaths—burning alive. Prejudice and habitual idiocy apart, can anything be clearer than this, that, as fire mounts and smoke stifles, all persons who are above a fire ought to be enabled to leave the house by way of the roof, as easily and rapidly as those below the fire can go out of the street door. Now what do the builders do? They side with fire; they accumulate combustible materials on the upper floors, and they construct a conical roof most difficult and dangerous to get about on, but to the aged and infirm impossible. Are then the aged and infirm incombustible? A thousand poor wretches have been murdered in my time by the builders with their small trapdoors and their conical roofs. Thousands more have been destroyed, as far as the builders were concerned; the firemen and fire-escape men saved them, in spite of the builders. The fire-escape can after all save but a few of the builders' victims. The only universal escape is—the RATIONAL ROOF."

Mr. Reade then goes on to enumerate the many and real advantages of the Rational Roof; but among them we do not find the greatest of all, an excellent site for a garden. The roof-garden may be easily made, and in various ways, as the climate, taste, or means of the owner of a Rational Roof may desire. Nothing can be simpler, for example, than to turn the upper floor into a conservatory. A capital suggestion towards this end is that which has been made by Mr. S. B. Parsons, of Long Island, in the *American Agriculturist*:

"It is," he says, "within the means of any man who builds a good house to have a garden on the roof, which, during the summer, can be filled with the most luscious grapes, peaches, plums, &c., and in the winter with plants, the beauty of the flowers of which will afford a charm far beyond the trifling cost of their maintenance. A glass roof costs very little more than a tin or slate one. Let the roof, therefore, be covered with glass, and let the upper floor be covered with concrete, sloping gently from the centre to the sides, around which a slight depression in the floor can carry the moisture

Fig. 1. Roof Conservatory.

or drip into the leaders which pass from the roof of every house to the ground. With this slight expense, a perfect greenhouse may be had. A Mansard roof glazed in this manner is shown in figure 1. Now for heating. Everyone knows that the upper rooms of his house are so warm from the ascending heat of his furnace, that registers are scarcely needed. Let the doors be kept open, and the waste heat of the house will keep the top at the highest desirable temperature. Thus the greenhouse is heated without any extra trouble or expenditure. Its care would be a pleasant recreation for any of the family. The pleasure of cutting one's own flowers, or sending to a friend one's own roses, or camellias, or Black Hamburg grapes, is not to be despised. In case the demands of the counting-house or the drawing-room are too engrossing to allow any attention to flowers, there are numerous florists in every city who would be glad to keep such a place in perfect order for a very moderate compensation. If a little extra strength is given to the beams which sustain the upper story, sufficient earth could be placed there to lay out the whole space of twenty-five by fifty feet as a garden, with winding-yalks, carpets of moss and roses, camellias, &c., planted

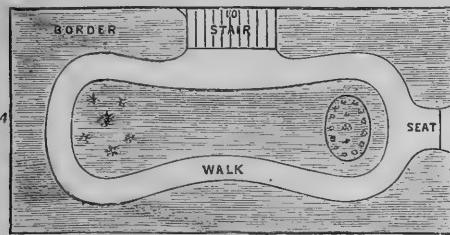

Fig. 2. Plan of Roof Conservatory.

in the soil, as shown in the plan. By this mode the illusion will be complete, and in the middle of winter one may have a tropical landscape. But, for fruit as well as flower culture, the use of pots will be preferable. Let us see what can be done with these. The superficial area of nearly every good city house is more than twelve hundred square feet. This would contain quite an orchard of fertile little fruit-trees. If one wishes no flowers, but fruit only, he can have forced peaches and nectarines at a season when he cannot buy them for less than a dollar each. But if it be desired to have the house filled with flowers through the winter, we cannot cultivate forced fruit. We can, however, have flowers, stone fruit, and Black Hamburg grapes in succession. If the house has been filled with flowering plants in the winter, and there is plenty of yard room, they can be taken out and arranged in groups in the yard as soon as all danger of frost is over. The house can then be filled with peaches, plums, and nectarines in pots, which can be obtained of the nursery-

men ready for fruiting, or prepared the previous year by the florist having charge of the house, and kept in the cellar during the winter. These can remain in the house until the fruit has attained sufficient size to be safe, when they also can be grouped in the yard, where they will grow, and ripen early and well. Their place in the house can then be supplied with grapes in pots which have been retarded by being kept in a cool, dark place in the cellar. These will then bear abundantly during the summer, and, before the flowering plants require to be taken in the ensuing autumn, will duly respond to the tiller in Black Hamburgs and Muscats. Two pounds to each vine, or four hundred pounds of grapes, would be a moderate estimate for the space mentioned.

"Both stone fruits and grapes are easily managed, and a man of ordinary intelligence could soon learn to grow them, even if his life has been passed in the midst of dry goods or hardware; if, however, his own skill fails him, florists are always attainable. Here, then, are now luxuries—flowers, peaches, and grapes—within the reach of every man of moderate means. If the capabilities of this plan and its economy were thoroughly understood by architects and proprietors, the time would soon come when a roof-garden would be considered just as essential an appendage to a house as a bath-room. The demand for care-takers would bring forward a host of candidates for this new branch of industry, and it might furnish an excellent and remunerative vocation for women."

THE PRINCE GARDENER.

A TALE OF TRANSPLANTATION.

WHEN Catherine II. of Russia was about to visit her prime minister, Potemkin, on one of the vast estates she had conferred upon him, the imperial favourite perceived, for the first time, that the estate then in question, the most recent gift of the Empress, a few versts from Smolensko, was very bare in aspect, not being varied by the form of a single tree bigger than a trailing cranberry-bush. The vast domain had been made over to him—the land and its inhabitants—all in one lot; the numerous serfs bringing up his general holdings of that kind of property to over thirty-six thousand. Serfs enough, and to spare—but, then, there were no trees; for it was far easier in many parts of Russia to grow serfs than timber; and this stubborn fact both vexed and puzzled the almost omnipotent minister.

It is very true that at several of his residences near St. Petersburg, and in other places, he had managed, by mere force of will and lavish expenditure, to create *jardins Anglais*—the mania of the day—with their slopes of turf and artificial streams and rustic bridges, despite the opposing forces of the glacial climate; but to create ancestral woods round about the castle-palace which he had hastily improvised at Smolensko was a far different matter. There was not a single forest, large or small, within a couple of hundred versts or so; a distance of not much account in the vastness of the Russian empire, but yet a rather stiffish one for the moving of big forest trees.

And, moreover, there was but a fortnight to spare from the time he had first perceived the barrenness of his lands to the time appointed for the visit of the Empress. Yet Potemkin made up his mind that the estate must, somehow or other, be timbered with majestic trees within that narrow space of time. Prince Potemkin was a very great man, and also a very big man—stalwart as the mighty men of Bashan. In fact, his huge stature led the Prince de Ligne to remark that his person symbolised the vastness of the empire over which his genius presided; and the great, big man, simply determined that the great forest of Slavonka, though two hundred versts to the south-east, should furnish forth the big trees that he required; and within a fortnight, by a lavish expenditure of the sinews of gardening, which are of precisely the same nature as the sinews of war, the thing desired was accomplished, with a day or two to spare. Noble groups of oaks, of gigantic size, and towering firs—those cypresses of the north—and a variety of other trees of noble growth and luxuriant foliage, being made to enrich the bare land round the castle-palace of the great minister.

On the eventful morning of the Empress's arrival, however, to his great mortification, his imperial mistress betrayed neither surprise nor delight. Empresses have spics as well as eyes, and often find the former of much more real service than the latter. In fact, she knew all about the improvised ancestral groves, and where they came from, and how they got there.

The chronicler, after the manner of his class, does not tell us how it was done—those gentry are generally very reticent where one would wish them to be diffuse, and frequently somewhat diffuse where they might well be excused for a little reticence.

One would have liked to be told how a thousand or so devoted serfs dug up those lords of the forest, with great boles of earth about their roots; and how a couple of score of the sinewy little horses of the

Don were harnessed to each of tis strong-cross six-wheeled waggons, on to each of which a tree had been secured, "by a powerful derrick; and how each tree was supported in an leaning position, and prevented from swaying by a strong and well contrived framework; and how each team of the tough little horses had been lashed along at a gallop, through each relay, for the whole of the two hundred and odd versts. But the chronicler does not tell us either of this, or any other *modus operandi*, contenting himself with inuendiendo that the Empress herself knew all about it, and that she was by no means startled, as her favourite minister had expected, at the sight of those noble groves where all had been a bare desert, only a fortnight before.

"They look very well," she remarked, with phlegmatic coolness ; "but scarcely as well, and will scarcely prove as useful, as the forests of white mulberry which I planted in the Ukraine, to establish a silk-culture. Nevertheless, they look well—quite as well as they did at Slavonka, if not better; especially this big fir with the double stem. I happened to be hunting there a week or ten days ago, and admired it. Slavonka, prince, is an imperial domain. I think even my prime minister might have asked my permission before taking upon himself to remove so noble a stick of timber."

Potemkin's face involuntarily elongated itself, and he was about, as the Empress perceived, to throw himself at the feet of his imperial mistress, and so, with a sudden movement full of that majestic grace which it is said none can assume who are not born in the purple, she said, in that soft, low, and yet stinging voice which makes disgraced favourites tremble :

"Stay, Prince Potemkin; stay!" said she approaching the table beneath the great forked fir, where a magnificent collation had been sumptuously prepared, a magnum of the priceless imperial Tokay being placed for each of the guests. "Stay, prince," she repeated in the same emphatic whisper, as she seized one of the magnums; "stay, prince. If you persist in flinging your huge body at *my feet* I will fling this magnum of Tokay at *your head*."

He was, however, already crouching before her, his grand head prone to earth, like that of a slain giant.

So, putting down the magnum with a grave dignity that made the ladies of her suite long to be empresses likewise, she took her riding-whip in her right hand, and drawing herself up to her full height, and looking every inch an empress, she whisked it swiftly above her head with a rapid wave of her tolerably muscular arm, suddenly bringing it down with a slashing flack across that part of the prince's Hussar pantaloons just where they were strained to the very tightest by his crouching position, saying, with that fascinating grace of manner that sovereigns alone have always at immediate command,—

"Rise up, Prince Gregory Alexandrovitch Potemkin; rise up a knight of the first class, of the Imperial Order of the Two-headed and Four-legged Eagle."

And then Potemkin rose, as a true knight should, appearing perfectly at his ease, bowing, and smiling too—at all events on the side of his mouth next the Empress—and saying, with his hand very properly on his heart, "Your imperial majesty is ever too gracious to the most devoted of her subjects."

And then the whole party sat down to the magnificent collation, but no one said much till the Tokay began to circulate; for the imperial suite, as the handsome young Soltikoff remarked, *sotto voce*, were all "rather flabbergasted."

The Empress herself was the first to revive the conversation, saying, "Potemkin, my dear giant prince, don't be frightened; the trees look ten times better than they did in my imperial forest; especially this great forked fir. You are a most accomplished gardener, Potemkin, and evidently know exactly what ought to be done with noble trees, whether belonging to yourself or anybody else. Their distribution here round about your splendid schloss is extremely well devised, especially that quincunx of great beeches on the slope, yonder. Nature, Potemkin, Nature unaided, is a mere ignoramus. She had stuck all those grand trees so close together in the forest at Slavonka, that at every bit of a gale they knocked their heads together *a tout rompre*, like great green boobies as they were, for staying there so long. But, I presume, Potemkin, they could not break from their fetters till you, the great gardener-magician, waved your magic money-bag at the end of the ever-persuasive knout, and released them from the thralldom of that wicked untaught fairy, old Dame Nature. Yes; you are a magician. All great gardeners are magicians; it is only they who, by the cunning of their art, can make the desert smile."

"And now I have another idea, prince," continued the Empress, who was always very voluble after a glass or two of Tokay, "Yes, I have another idea; I feel bound to honour the talent you have so strikingly displayed in the formation of these noble groves. The effect is at once grand and charming. It is a masterpiece of its kind; a metamorphosis—glorious metamorphosis! Special capa-

cities such as those here displayed, must be specially rewarded. There is an imperial domain in the extreme northern corner of eastern Siberia, which is extremely bare of—"

"Your majesty I supplicate—"

"Do not interrupt me, Potemkin. I was about to state that the domain in question is extremely bare of lofty trees. I am, however, not going to meddle with it just at present. But the present gardener of my Casino at St. Petersburg is evidently a silly little fellow. I have no faith in little men. You are a great, big fellow, Potemkin; evidently strong; and I hereby appoint you head-gardener at the Casino by imperial patent. Time of work, ten hours a day; pay, ten roubles a week. Those are my terms; and, as a favour, the blue aprons, which will be—" and she looked at the colossal dimensions of her new head-gardener—"the blue aprons, which will evidently be costly, shall not be deducted from your wages."

"But, your majesty, I merely caused these lofty trees—"

"Say no more about the *high trees*, Prince Potemkin, or I will make your crime *high treason*!" stormed the Empress, in a mock heroic strain, smiling in her sleeve, at the vile pun she was perpetrating. "Say no more, Sir Prince, or I shall be under the necessity of appointing you, also, stage-manager of all the transformation scenes of my grand opera, with ten hours night-work in addition to your day labours in the gardens of the Casino."

The Prince visibly remained silent, and the imperial party resumed their seats, and took to their Tokay fiercely, and, as we of these degenerate times might think, dangerously. But the chronicler whose record I am transcribing states, with that extreme *naïveté* which distinguishes his order of scribes, "they did not get drunk, because they were so used to it."

H. N. H.

THE ODOURS OF ORCHIDS.

In connection with this subject, to which allusion is made in your last number, it may be well to direct attention to the varying odour of the common Early Purple Orchis (*O. mascula*). During the day it is slightly fragrant; but towards evening it exhales a smell so unpleasant that it is unbearable in a room. This is the general rule, so far as my experience goes; but there are exceptions: for I have sometimes found specimens which even during the day were unpleasant, and others which were scarcely odorous at night. The perfume of *O. masculata*, never very powerful, is perceptibly stronger towards evening; while the rich aromatic odour of *Habenaria chlorantha* and *Gymnadenia conopsea* becomes overpowering at night. The rare Lizard Orchis (*O. hircina*) is said to have a very disagreeable smell. Probably there is no one order of plants which presents as great a variety in form, colour and scent, as the Orchidaceæ. Mr. Bateman gives the following list of some of the principal odours which he has noticed among them, with the plants that produce them:—

Cynochches Lodigisii, honey : Burlingtonia candida, citron ; Gongora atropurpurea, allspice; Maxillaria aromatica, cinnamon; M. atropurpurea, violets; M. erassifolia, noyeau; Epidendrum umbellatum, angelica; E. anisatum, aniseed; Aerides odorata, pomatum; Acropora Lodigisii, wallflowers; Oncidium ornithophorum, fresh hay; Bulbophyllum coccineum, cocoa-nut milk; Stanhopea grandiflora, a druggist's shop; Dendrophion moschatum, musk. The last-named species, however, appears to me to resemble Turkey Rhubarb in scent, and Professor Reichenbach is of the same opinion.

JAMES BRITTON, F.L.S., British Museum.

International Weather and Crop Reports.—Commodore Maury has just elaborated a plan for the universal extension of the weather-report service, and for the organization of an international system of meteorological stations, and the results to be effected by his scheme is to give the farmer, as well as the merchant in America as full and accurate information as is possible of the crops in every part of the United States, in England, the basin of the Black Sea, in Egypt, and the Danube, as they have in their own neighbourhoods; and to secure reliability, it is thought the duty of collecting the information should be undertaken by the Governments of the co-operating countries. It is, therefore, suggested that at first a special committee should be appointed, consisting of 10,000 farmers and merchants in the United States, that two reporters should be employed in Great Britain, nineteen in France, one in Belgium, one in Holland, and so on—the machinery of electrical communication being already at hand.

Vegetation on Stone Walls in England.—If the roadside happens to have no hedge, the ugliest stone-fence (such is, in America, would keep itself bare and unsympathizing till the end of time) is sure to be covered with the small hardwork of Nature; that careful mother lets nothing go naked there; and, if she cannot prevent the stones from growing over, she will, at least, make them fit into the stones and interlock as a part of her original plan, treating the hard, uncromy construction as if it had all along been a favourite idea of her own. A little sprig of ivy may be seen creeping up the side of the low wall and clinging fast with its many feet to the rough surface; a tuft of grass roots itself between two of the stones, where a pinch or two of wayside dust has been moistened into nutritious soil for it; a small bunch grows in another crevice; a deep, soft verdant moss spreads itself along the top and over all the available inequalities of the fence; and where nothing else will grow, lichens stick tenaciously to the bare stones and varigate the monotonous grey with hues of yellow and red.—HAWTHORNE.

THE GARDEN.

"This is an art
Which does mend nature : changes it rather ; but
THE ART IS NATURE."—*Shakespeare.*

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER.

All questions on Horticultural matters sent to "THE GARDEN" will be answered by the best authorities in every department. Correspondents, in sending queries, are requested to write on one side of the paper only.

The Name and Address of the writer are required with every communication, though not for publication, unless desired by the writer. Letters or inquiries from anonymous correspondents will not be inserted.

Readers who may find it difficult to procure the numbers regularly through the newsagents or booksellers, may have them sent direct from the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance.

PUBLIC GARDENS.

PARKS AND PUBLIC GARDENS IN AMERICA.

When starting for the "great country," as Americans justly call theirs, I said to myself, here we break new ground in this as in many other matters; here the necessities of defence from the enemy have not forced men into foul ruts, so narrow that the fresh breeze of heaven is powerless to drive away their pollutions; here, where land is yet so abundant, I shall doubtless find room left in the cities for a few trees or a little verdure here and there to make them more fitting abodes for intelligent beings than the human burrows of old countries; here, with a young and giant nation starting into unexampled growth, untrammeled by the traditions and many evil circumstances that prevail in "old countries," we shall see, if not fine houses or buildings, room enough in the streets for the convenience of business and for the future development of the commerce of the cities. Not so by any means! No "rookery" of old countries is fouler than the tenement houses in New York; no large city I have ever seen in Europe is so devoid of squares or open spaces. Bad as London is, I have never seen such inconvenient interruption of traffic in its streets as I have witnessed in Broadway. In all American cities, with one exception, the streets are long and straight and narrow, and that is all you can say for them. Once I found myself in the street I had been searching for, and, asking for No. So-and-so, was told, "Five miles further on, on the right!" They boast of streets eleven and even nineteen miles long. Is that not a great thing? As for squares, they are few and far between, and when you do find one, it is wretchedly managed, on the good old principle of planting a tree wherever there is room for one. But there is, perhaps, excuse for some of these things. In many cases, when the cities were designed, it would have been rash to suppose they would ever have attained one-tenth of their present size; and if they had as big streets and foot-paths as in the old country, was not that enough? But there are signs that the great cities are beginning to be ashamed of this state of things, and here and there, in some of them, there

indications that the newer portions will be very differently spectated on.

replaced by a however, two distinct kinds of public gardens noble effect of Americans seem destined to surpass us im- will exist in Parks and cemeteries. It is amazing to witness the New extent of their parks, and to hear of the vast of old riverside upon them; while their cemeteries are as far listed to make it have seen in Europe as the tomb of Napoleon remind those who before one of the little cells in Père la Chaise, that we have now to see such noble parks in such a young and that, in the eur well for public gardening there when the the right directions attained greater development. In most

The system of plarge cemeteries are sometimes so disposed

that they bear some resemblance to gardens, but in America they are so large and park-like and well planted that they are really public gardens of a high class, and there is none of that disgusting over-crowding of which there is so much in Parisian cemeteries, and also in those of London and many other places. Instead of the bodies being interred as thickly as matches are packed in a box, each family has a small plot of ground (lot) large enough to form a little garden, and in this the burials take place in an isolated manner. In Cincinnati they are even improving on this, by causing all the boundaries of the lots to be hidden beneath the turf, and by not allowing more than one slab or monument to each owner of a lot, on which the names of all the persons buried in it must be inscribed, if they are to be inscribed at all. In this way the unpleasant effect which results from covering a large extent of ground with thousands of monuments will be, in a great extent, removed, and the designer will be able to get very happy park-like effects, and quiet green lawns here and there.

New York, the chief city of the States, is, in some respects, the most disagreeable and filthy city I have ever seen. The famous Broadway is, in everything but in length, inferior to some of the second-rate Paris boulevards, and is, for a great city, a narrow street. There is very little good planting in the central parts of the city—those in which it is most wanted; and what has been done has mostly been in very narrow streets, so that when the Ailantus and other trees grow up, they grow right against the windows, or half fill up the street. The squares are few, and very inferior compared with those of Paris, or even those of London. They are usually crossed by straight walks, or dotted over with common-plac trees, so that no good effect is obtained. In the more fashionable parts of the town the streets are clean; but in hundreds of the secondary streets the filth is woful. The people have a good old fashion of throwing all their refuse into the streets, and the municipality allow it to rot there for an indefinite length of time. Dirty streets one often meets with, and ill-paved streets, but to find great boulders of paving-stones rambling away from their places, and allowed to roll about, to the danger or inconvenience of every passing vehicle, and to see whole streets unpaved, or, if paved, hidden from the eye by a thick-bed of mud, betrays a hopelessly-abandoned and unique degree of bad management! The New Yorkers certainly "beat all creation" as regards the bad condition of their streets. But in several things the city is very fortunate. Like all the great eastern cities of America, it is built on a noble harbour; and the island on which the city stands is flanked on one side by the wide Hudson River, and on the other by the East River, an estuary, and these form broad, breezy, water boulevards that effectually limit the densely-packed buildings, and have the most beneficial effect on the air and health of their surroundings. Then, again, the Central Park of New York is magnificent, as many already know. There is not much fine gardening in it, rightly, as I think; but, in point of design, it certainly is much better than any park we have in London. There are, in many places, nice, quiet breadths of open grass, and I have never anywhere seen so many great breaks of picturesque, natural rock crop up; fortunately these have been preserved, and now offer the finest positions I know of for planting with rock-shrubs and alpine plants. One thing seemed a mistake—the making of many bridges over roads, with a view to separate equestrians from pedestrians; this is the most expensive and needless crotchet I have ever seen. In the Bois de Boulogne and in Hyde Park we have a far greater number of equestrians, and no such thing is or will ever be necessary. When will the persons who arrange plans for such parks as these learn that park or garden is spoiled in proportion to the number of needless architectural works which it contains? This is particularly the case in a city. There should be no building in a public garden not absolutely necessary, and those that are indispensable should be inexpensive, and, as a rule, concealed by judicious planting.

The Greenwood Cemetery at Brooklyn is very large and beautiful (between 400 and 500 acres), varied in surface and well-planted. It is now, and, let us hope, will always continue, practically a public garden. Prospect Park, at Brooklyn, is also a very noble one, with a prairie-like sweep of open grass, and is generally very well designed. The approaches to and

some of the roads near this new and large park are very broad and dignified; and the whole is truly worthy of the "great country." If other American cities go on in this way, old Europe will soon be left far behind in the matter of public gardens.

(To be continued.)

NOTES AND QUESTIONS ON PUBLIC GARDENS.

Finsbury and Southwark Parks.—At a meeting which took place the other day at the Board of Works, a motion was brought forward to prevent the reselling of any portion of the ground bought for these parks, for building purposes. The principle involved in this motion, that the public should not profit by the creation of the parks, and then selling it again to an advantage for building, was condemned by some and thought justifiable by others. The question was, therefore, put to the vote, when there appeared for the motion, 22, and against it, 12. As the meeting was, however, for the purpose of rescinding a former resolution of the Board, it required to be carried by a majority of two-thirds of those who were present. There was not that number, and the motion was consequently lost.

Graveyard Desecration.—The most accursed act of vandalism ever committed by man, is the desecration of the sacred sepulchres in almost all of our city burial-grounds, and one at least just outside the city, and planting them in rows to suit the taste for symmetry of the perpetrators. Many years ago, when this disgraceful process was going on under my eyes, I addressed an indignant remonstrance to a leading journal. I suppose it was deficient in literary elegance, or too warm in its language; for no notice was taken of it, and the bygone horror was allowed to complete itself in the face of daylight. I have seen it go over the bodies of my own relatives, being carried beneath the common table, but the upright stones have been shuffled like chessmen, and nothing short of the Day of Judgment will tell whose dust lies beneath any of those records, meant by affection to mark one small spot as sacred, to some cherished memory. Shame! shame! shame!—that is all I can say. It was on public thoroughfares, under the eye of authority, that this infamy was enacted. The Red Indians would have known better; the select men of an African kraal would have known better; for they have a "soul like us," their dead restles which have been disturbed, or removed, and the ground leveled, leaving the flat tombstones; epitaphs were never famous for truth, but the old reproach of "*Heres lies*" never had such a wholesale illustration as in these outraged burial-places, where the stone does lie above, and the bones do not lie beneath.—*The Autocrat of the Breakfast Table.*

Victoria Park.—In reference to the dissatisfaction which has arisen in the east of London respecting the covering of the immediate surroundings of this park with buildings, its preservation society states, 1st. That the land, with which the company of Victoria Park is endowed by the crown, by virtue of an Act of Parliament passed in 1842. The Act empowered the Crown to purchase 290 acres, and stipulated that one-fourth of the land so purchased should be reserved for building lots, and that the remaining three-fourths should be set aside to form the "park." The object contemplated in the reservation of one-fourth of the entire quantity of land purchased under the Act was to provide a revenue to the Crown from the rents of the ground, and to provide a park and 290 acres of open ground for the public, about seven acres comprising the outer portion and constituting a "belt" of land surrounding it, were reserved, it being intended that the houses erected on the Crown land should encircle the park. 2nd. From 1842, when the Legislature framed the Act, to the present time, the clause authorising the reservation of the encircling belt of land has practically, to a great extent, remained inoperative. The public have used the enclosed space, no doubt concerning it as a park, and the park, though having proved a failure, the land not having let in the advantageous manner that was anticipated, and the greater portion of the original seventy acres still remaining an open space. 3rd. The thirty years which have elapsed since Victoria Park was first laid out have produced a marked and striking change in the east of London: The fields and open spaces which existed in 1842 no longer remain, but have given place to a dense mass of street, laundry, and alleys, built with a hard-working, industrious population. The park, which was intended for the people, many years ago, is too small for their present requirements. It is therefore fair to ask Parliament to abandon the right to build upon any portion of the open space surrounding Victoria Park, in order to give that space to the people for their hard-earned relaxation and enjoyment.

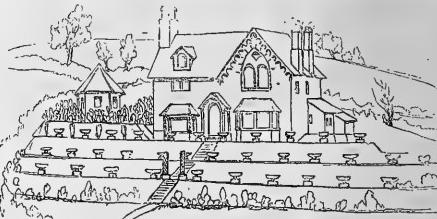

THE TWO PATHS.

THE TERRACE GARDEN.

It is commonly believed that we have now arrived at a wonderful degree of horticultural excellence as compared with other nations; this is probably the case, but nevertheless we are just reaching a stage from which we can get a clear conception of how very little we do that is really creditable, and of how many absurd things are perpetrated in the teeth of the very simplest laws of true taste.

The terrace garden is a strong case in point. It is most unfortunate that in the present stage of our horticultural progress we are blessed with a number of landscape gardeners, who, having had few opportunities of acquiring a love for nature except where she is trained into true geometrical proprieties, and having little or no knowledge of art, fix their minds upon the terrace garden as the acme of perfection in garden design. It is the one tangible thing, about the propriety of which there can be "no mistake." Hence the many violations of that repose and grace which should characterise the immediate surroundings of country residences and villa gardens. Terrace gardens are made in all sorts of positions. Considerable expense is incurred in the removal of masses of earth, where it would

have been in much better taste to have left the ground as it was; and an immense amount of trouble is taken to produce ponderous eyecoses, which our descendants will be at considerable cost to remove, should they desire to peacefully inhabit the same abodes. Undoubtedly we may here and there find associated with some princely mansion, and where the sweep of pleasure-grounds is so wide that terraces seem merely to form a resting-place for the mansion, a terrace garden not offensive to taste; and we know that in some cases the nature of the ground commits us to the style. But we also know that even in connection with the most princely mansions terrace gardens are often not only made where they are not required, but where they are positively destructive of the beauty of the scene. The costliest and most pretentious delusion in all ornamental gardening is the making of an elaborate terrace garden in a place where, from the size of the grounds or the portion of them devoted to ornamental gardening, the terracing and geometry, and

all their accompaniments, constitute the chief or only features. The house and garden in the accompanying illustration are situated near York, in a pretty undulating district. It is not a place from which the ground sweeps widely away from beneath the terraces, but nearly the whole is occupied by the three banks, &c., shown in our woodcut. It is not the owner who is to be blamed for thus disfiguring the fair face of nature. We understand that he acted on the advice of "a very good landscape gardener." It would have been pleasanter to have described this place as a relic of the past, but it is not so. It surprised me when I beheld it for the first time this summer, growing like a big fungus on what last year was a pleasant meadow. If things go on in this way the tenth of the expression that "God made the country and that man made the town" will not be so apparent as it has been. We fill the valleys of once fair districts with foul smoke, and sit among the cinders; but this some do for money, and many for life's sake; but that rational beings should, for their pleasure or amusement, place under their eyes for life such scenery as we have figured is indeed disheartening.—*Field.*

The Abelia.—These form a small group of ornamental shrubs belonging to the honeysuckle family, and are chiefly natives of N. India, Japan, China, and Mexico, bearing opposite leaves and handsome tubular flowers. They are less known in gardens than many subjects which have no claim to beauty, and placed in suitable positions, are capable of producing most pleasing results. *A. triflora*, one of the seldom-seen, is a native of high mountains in N. and W. Kumaon in N. India, where it is called kumki. It bears a profusion of flowers, of a pale red or rosy colour; deliciously sweet, and arranged in threes, forming corymbs. In some of the warmer parts of the south this may succeed as a shrub. Near London it succeeds perfectly on south walls in light, well-drained soil, and well trained out and spread over garden walls form a beautiful object. *A. floribunda*, from Mexico, bears rich purple-red flowers, in drooping leafy panicles. In some of the warmer parts near the coast it may be grown as a shrub, but generally it will thrive best on a wall, and like the preceding, it forms a very ornamental wall shrub, as does the Chinese *A. uniformis*. In this species, however, the flowers occur singly, as the name would imply, but in threes, a somewhat closely set panicle. *A. rupestris* is a dwarf shrub, which we have seen covered with rose-late in the autumn in Devonshire. There are various but the preceding are the best of the introduced kinds at first considered stove and greenhouse plants, and the country the temperature of the greenhouse or often be necessary for them; but if we possessed of *A. rupestris*, all open-air gardens in the southern islands might be highly embellished by these charming

A New American Boulevard.—A forty-mile boulevard is said, about to be built along the Hudson River.

THE THAMES EMBANKMENT.

BY NOEL HUMPHREYS.

THE most noble of the recent additions to the splendour of our British Babylon is, undoubtedly, the Thames Embankment. Its river face is so grandly simple, that it utterly dwarfs all the works of the kind, even the long-vaunted quays of the Seine; while those of the Liffey, in Dublin, once held up as a model to the imperial capital, sink into insignificance.

Thames Embankment, 1800.

It is, perhaps, well that the first designs of embanking the Thames, and the creation of noble riverside roadways, as proposed by Colonel French and by the celebrated painter, John Martin, some forty years ago, were utterly scouted by the officials of the day, and by the good public also, as wild and Utopian schemes. That they were so scouted, is not, perhaps, regrettable, as the carrying out of such projects at that time would scarcely have been done so thoroughly and on a scale so grand as now, though Waterloo Bridge had already been

the best one, though any amount of authority might be adduced in justification of the course pursued. In the first place, we find that only one or two kinds of trees have been planted along the whole course of the great new roadway—a most unpardonable overlooking of the great variety of noble trees well suited for the purpose and the situation, a judicious selection from among which would not only have secured greater diversity of effect, but have secured a vast increase of beauty at the same time.

As examples of noble trees that should have been found along the line of the great water-wall, of which we are so justly proud, the following may be named out of a score or more, all of which are suitable for the purpose:—The noble Gleditschia should have been one of them. It is a much finer tree than the well-known Robinia, retains its foliage in perfectly green condition till very late in the autumn, and, if well planted, often attains the height of eighty feet. The great Norwegian Maple is also a tree that would do well, and form a fine contrast with commoner trees. There is also the pyramidal variety of the common London Plane; and then comes the Ailanthus glandulosa, which thrives well in towns. Also the flowering Ash (*Ornus europaea*), and the *Celtis occidentalis*, and the Tulip tree, which last is quite at home in London; and there are many others equally desirable. Secondly, as regards planting trees along the line of the Embankment there is a principle of still greater importance than variety of foliage to be observed: it is the leaving of open spaces at certain distances; so that, ever and anon, glimpses of the noble buildings which we hope to see ranging east and west from Somerset House, may be obtained by the spectator with striking effect.

The accompanying woodcut shows how grandly the aspect of fine architecture meets the eye when the view is flanked by foliage. But with a continuously-planted avenue, such a view can only be obtained at each end; so that when the projected

Thames Embankment, 1871.

completed with such a breadth and grandeur of style as led critics to call it a work worthy of the Pharaohs.

When the mean houses which now show their backs to a spectator on the great roadway and gardens shall have been replaced by a line of stately edifices worthy to continue the noble effect of Somerset House, nothing so grand of its kind will exist in Europe, unless the rumoured project of embanking the Neva should be made to surpass it. The annexed sketch of old riverside buildings, taken just before they were demolished to make room for the great Thames wall, may serve to remind those who have already forgotten them and their likes, that we have now something very much better in their place; and that, in the embellishments of London, we are moving in the right direction, though slowly.

The system of planting adopted on the Embankment is not

straight and uninterrupted row of high-growing trees is completed, it will, as seen from the river, form a far-stretching green wall, entirely concealing from view the long range of grand public buildings which are, at no very remote period, destined to form the finest feature of the Embankment.

The spoiling of our noble Thames Embankment near the Houses of Parliament—that is to say, at its most important point—by allowing it to be narrowed by several private gardens, shut out after our too common exclusive practice by an ugly dead wall, affords a good illustration of the ignoble selfishness that too often characterises us. Nowhere except in Britain would a few wealthy individuals be allowed to spoil what is probably the noblest point of view to be found in any city. There is certainly nothing equal to it in Paris, or in any other city with which we are acquainted. One would, at first

suppose that intelligent and wealthy individuals, who have country seats to retreat to when tired of the town, would use their best efforts to prevent such mean disfigurement of a noble, national work, instead of holding out for their "rights." The latter, however, seems to be their only aim. The case is thus alluded to in the *Graphic*:

"The report of the Commissioners of Woods and Forests throws some light upon the history of the ugly dead wall which has been permitted to disfigure the Thames Embankment for some five hundred yards eastward of Westminster Bridge. This wall, as is well known, cuts off a considerable space of the land reclaimed from the shore of the Thames, which is now laid out as private gardens for the convenience of certain persons residing chiefly in Richmond-terrace and Whitehall. These favoured individuals are lessees under the Crown at rents greatly below the present value of their holdings; but to these advantages it has for some reason been thought proper to add that of enjoying ornamental pleasure-gounds in the heart of London at rents so low, that they can only be regarded as nominal. For example, the Marquis of Westminster has a considerable portion for a term of thirty-four years at a rent of £3 2s. 6d. per annum; Sir John Ramsden another portion for fifty-one years at £2 a year, and so forth. The entire space thus cut off from the public for one or two generations does not appear to produce £50 a year to the Crown; and it is absurd to suppose that there would have been any difficulty in inducing the metropolitan ratepayers or their representatives to pay a much larger annual sum for the sake of adding this valuable space to the ornamental pleasure-gounds of the metropolis. It is at least certain that these gardens have been let for a consideration infinitely below the real annual value of the land. The excuse, we believe, is that the Crown lessees, being cut off by the Embankment from access to the river, were entitled to some compensating advantages. The lessees, however, have not been deprived by the Embankment of one foot of ground included in their leases; and the privilege of access to the muddy shores of the Thames had long ceased to be a practical advantage. If they were to be compensated for the loss of this, there would certainly have been no injustice in limiting the compensation to a strict estimate of its money value, as is customary when land is taken by railway companies under compulsory powers of purchase. Though it is probably now too late to get rid of the dead wall, it is to be hoped that the dealings of the Commissioners with the Crown lessees will yet even engage the attention of Parliament; but the fact is, that the whole system pursued by the Commissioners in dealing with the Crown rights urgently demands inquiry."

We trust it is not "too late to get rid of the dead wall," and that this scandalous example of injury done to a magnificent public work for the gratification of a few may be one of the last of its kind.

THE FLOWER GARDEN.

DUTCH COTTAGE-GARDENS.

BY NOËL HUMPHREYS.

THERE are many striking peculiarities about the dwellings of the working classes, in Holland, which are well worthy of the attention of travellers, who generally, however, make very short work of their tour through that interesting little country; hurrying from the picture galleries of Amsterdam to those of the Hague and Haarlem, to the great canals of commercial Rotterdam, and leaving themselves no time to spare for the study of the home life of the poorer orders, which presents many points of great interest.

It is, for instance, a *sine quâ non* with the working Hollander that his dwelling, however small, shall be entirely distinct and separate from any other. It thus happens that where space is valuable the width of the entire house very often does not much exceed that of the front door, so that a bed of ordinary size nearly fills a room, only leaving a narrow passage to a back apartment of similar dimensions, and sometimes to a second and third, in like manner. Even in the so-called blocks of buildings which have been recently erected in and near the large towns, the separate principle is strictly observed; each little slice of a house being surrounded with a garden, without which a Dutch artisan, however humble, could not exist; for the love of flowers in Holland is not confined to the great bulb-growers, whose hyacinth and tulip fields are reckoned by the acre, but it also pervades the general population. It is

true that there no longer occur epidemic manias for mere varieties—such as black tulips or yellow hyacinths—but there exists a steady, general love of flowers, for their beauty rather than their mere variety, which is a much more satisfactory formation of things.

The formation of the soil of the Dutch Netherlands is peculiarly favourable to bulbous plants; especially many of those from the Cape, which are so difficult of cultivation with us. The universal substratum of sand, in many places at less than a foot below the surface, affords the unusual combination of thorough drainage with continuous moisture in a way that is most beneficial to the class of plants referred to, which appear absolutely to require a deep bed of sand immediately beneath the rich surface soil in which they are planted. Sand, indeed, seems the one great necessity of many kinds of bulbs. This was curiously exemplified in the well-known story of the Guernsey Lily, so called, it is said, on account of its European *début* on the sandy shores of that island. A vessel having a large number of those bulbs on board (the first importation) was wrecked on that dangerous coast, and the following spring the sands of that side of the island were studded far and wide with the rosy heads of flower of that elegant liliaceous plant, which will not flower with anything like such luxuriance under the most careful greenhouse treatment as it did that spring on the bare sea sands of Guernsey.

The garden soil of Holland, is an entirely artificial creation, possessing the vital sand element, which, as we have said, is similarly favourable to many, if not most, classes of bulbous plants; and I have seen the *Ixia*, the *Sparaxis*, and many of the rarer Cape bulbs expanding their dazzling flowers in a Dutch cottage-garden, while they reject all the blandishments and caresses of an English gardener, refusing to display their beauties in anything more than such a shabby fashion as renders them hardly worthy of culture in our soil and climate. A thoughtful consideration of the natural advantages of these Dutch cottage-gardens may, however, lead us eventually in the gardens of our English homes to the more successful culture of those dazzling Cape flowers, which (as Schiller finely said of flowers in general) may more especially than any others be called "the stars of earth."

THE WILD-GARDEN.

COPSES, HEDGEROWS, LOW THICKETS, ETC.

Our wild flowers take possession of the stiff, formal, and shorn hedges that seem the land, often draping them with such infinite grace and beauty that half the conservatories in the country, with their collections of small red pots and small mean plants are horrors, compared with a few yards' length of their blossomy verdure. The Wild Roses, and the Purple Vetch, and the Honeysuckle, and the Virgin's Bower, clamber above smaller, but not less pretty, wildlings, and throw a veil of graceful life over the mutilated shrubs, reminding us of the plant-life in the nest-like thickets of dwarf shrubs that one often meets on the high Alpine meadows, where you may gather flowers after they have been all browsed down on the turf—small islets of little trees in a sea of grass. Next to the most beautiful Alpine vegetation, there is, perhaps, in the world of plant-life, nothing more lovely than the delicate tracery of low-climbing things wedded to the bushes in all northern and temperate regions of the earth. Perishing like the grass, they are happy and safe in the earth's warm bosom in winter; in spring they peep up to look at the sun as the buds swell in May, and soon after, finding the bushes once more enjoyable, rush over them as joyously as children from school to a meadow of cowslips. Over bush, over brake, on mountain or lowland copse, holding on with delicate but unyielding grasp, they toss their blossoms in the breeze, and engrave themselves for ever on the mind as the central type of graceful loveliness. Then, in addition to climbing Pea-flowers, *Convolvulus*, &c., of which the stems perish in winter, we have the great tribes of wild vines, noble in foliage and often in fruit, the Virginian-creeper, looking even happier when garlanding the homes of men than in its native woods, and blushing as deeply before its winter death on the British cottage or copse, as on the rocks of the Hudson on the cliff-walls of Niagara; the numerous Honeysuckles, from coral red to pale yellow, all beautiful; and the Clematis, rich, varied, and lovely beyond description, from those of which each petal reminds one of the wing of some huge tropical butterfly, to those with small flowers borne in showers like drops from a fountain jet, and often sweet as Hawthorn blossoms, with a host of others too numerous by far to name.

This type of vegetation may be trained and tortured into ten thousand forms in gardens, but never will its full beauty be seen until we entrust it to the garlanding of shrub, and copse, or hedge-row, frings of dwarf plantation, knots of rough shrubs, &c. All to be done is to put in a few tufts of any desired kind, and leave them alone, adapting the kind to the position. The large, flesh-coloured Bindweed, for example, would be best in rough places, out of the pale of the pleasure-ground or garden, so that its roots could not spread where they would be unwelcome; while a delicate Clematis might be placed beneath the choicest specimen Conifer, and allowed to paint its rich green with fair flowers. The common Everlasting Pea, trailing over a graceful young Deodar about ten feet high, was one of the most chaste combinations I have ever seen. In nature, we frequently see something of this kind, as for example, a Honeysuckle clambering up through an old Hawthorn tree, and thus struggling with it as to which should produce the greatest profusion of blossoms—but in gardens not yet. Stupidity will say that this cannot be done in gardens; but it can be done infinitely better in gardens than it has ever been done by nature; because, for gardens we can select plants from a hundred climates, and effect contrasts, in which nature is poor in any one place in consequence of the comparatively few plants that naturally inhabit one spot of ground. "This is an art which does mend nature—changes it rather: but the art is nature," is peculiarly applicable here in gardening matters. People seldom remember the art itself is nature; and foolish old laws laid down by dim-seeing old landscape-gardeners are only fertile in perpetuating the notion that a garden is a work of art, and therefore we must not attempt in it to "imitate wild nature."

Old stumps and old trees, &c., may of course be embellished in the most charming way with this type of vegetation. Sometimes, where there are large and bare slopes, a capital effect may be obtained by planting the stouter climbers, such as the Vines, Mountain Clematis, stronger Honeysuckles, &c., in groups or masses on the grass, away from shrubs or low trees; while when the banks are precipitous, or the cliffs crop forth, superb effects may be gained by allowing a curtain of climbers to fall over them.

Endless charming combinations may be made in this way in many spots near most country houses. The following is a list of suitable plants for the purpose:—

<i>Ampelopsis</i>	<i>Cynanchum acutum</i>	<i>Lycium</i>
<i>bipinnata</i>	<i>monspeliacum</i>	<i>europeum</i>
<i>cordata</i>	<i>Dioscorea Batatas</i>	<i>Medicago</i>
<i>hederacea</i>	and any other hardy species	<i>falcata</i>
<i>tricuspidata</i>		<i>Menispermum</i>
<i>Apio</i>	<i>Habitia</i>	<i>canadense</i>
<i>tu-borosa</i>	<i>tamnoidea</i>	<i>virginicum</i>
<i>Aristolochia</i>	<i>Hedera (all the finer</i>	<i>Pasque-flower</i>
<i>Siphon</i>	<i>varieties of Ivy,</i>	<i>carnaria</i>
<i>tomentosa</i>	<i>both green and var-</i>	<i>Periploca</i>
<i>Asparagus</i>	<i>iegated)</i>	<i>gracca</i>
<i>Broussonetia</i>	<i>Jasminum</i>	<i>Polygonum</i>
<i>Boussongantia</i>	<i>bulidiflorum</i>	<i>complexum</i>
<i>baselloides</i>	<i>officinale</i>	<i>Roses in great variety</i>
<i>Calystegia</i>	<i>rotundatum</i>	<i>Rubus</i>
<i>thunbergia</i>	<i>grandiflorus</i>	<i>biflorus</i>
<i>pubescens</i>	<i>latifolius</i>	<i>Smilax, hardy kinds</i>
<i>Cissus</i>	<i>rotundifolius</i>	<i>Tamus</i>
<i>orientalis</i>	<i>others</i>	<i>communis</i>
<i>Clematis</i>	<i>Loniceria</i>	<i>Tropaeolum</i>
<i>flammula</i>	<i>rotundifolium</i>	<i>pentaphyllum</i>
<i>montana</i>	<i>confusa</i>	<i>speciosum</i>
Vitis and other	<i>flava</i>	<i>Vitis, various</i>
varieties	<i>japonica</i>	<i>Wisteria</i>
<i>Convolvulus</i> , in var.	<i>Periclymenum</i>	<i>frutescens</i>
<i>Coronilla</i> , varia		<i>sinensis.</i>
<i>Cucurbita</i> perenns		

CONDUCTOR.

TREES IN TUBS FOR TERRACES.

We are no admirers of trees in tubs on terraces. They are always somewhat expensive, and rarely ornamental objects. It is considered correct taste to use them in geometrically laid-out terrace gardens. We deny that it is good taste, and could point to many terraces where their absence is no blemish. A row of trees in tubs is no more necessary to the effect of the best type of terrace or geometrical gardens than a row of balloons; but, as the taste for employing them exists, we here simply attempt to guide it in the right direction. The culture of orange, bay, and other trees in tubs is a Continental custom, and much more desirable in parts of Northern Europe, where few evergreens can be grown in the open air, than in Britain. It is, as a rule, very much better performed on the Continent than and those who adopt it should know the conditions essential to here; success, as proved by the long practice of Continental cultivators. Although we now often see handsome specimens of hardy evergreens grown in tubs in this country, tender subjects alone were kept thus when the system originated. It was found that the oleander and orange trees could be grown very well by

storing them in any sort of half-lighted, frost-proof structure in winter, and placing them in the open air in summer; and hence these plants became very popular for that purpose. The most important thing to bear in mind as regards their culture is that all the growth of the shoots should be made in the open air, and this is annually proved by the best Continental growers. If that point is well observed, the culture of such subjects is simple enough. Let us next select suitable kinds for British gardens.

The first place must certainly be given to the Laurustinus, because, while furnishing a good effect as a mere evergreen, it also blossoms sweetly in winter, when flowers are scarce. By using this as a terrace plant, and housing it during the winter, we add a valuable ornament to the conservatory or even the house, for it may well be kept in-doors for a short time while in the full flush of bloom in winter. In places where the plant is sometimes killed out of doors, or does but poorly, it would be all the better and more attractive grown in this way; and as it flowers in our dull, wet winter, the bloom on the plants under glass opens full and well. Indeed, it is well worth growing as a winter-flowering conservatory plant in districts where it does not bloom well out of doors. This, like most subjects grown in tubs, is usually trained as a standard, with a compact, roundish head. The shrub is trained in this form to a great extent by the Belgians. In summer the plants should of course be allowed to stand out of doors, and receive thorough waterings as they require them, letting them remain in the open air till late in the autumn, when they may be taken in-doors to a cool house of some kind, be it orchard-house or conservatory, provided that they are placed in some position where their beauty may be seen when in full perfection. When out of flower they ought to be trimmed in, and then kept in a cool house till all danger of severe frost is gone, when they may be placed in the open air again. It is of importance that their spring growth does not start till they are placed in the open air; therefore we think an out-house of some kind would not, after all, be the worst place for them for a few weeks before they can be turned out. As to soil, slightly enriched turf-loam will do capitally.

The bay-tree (*Laurus nobilis*) stands next in point of merit for this purpose. Although its flower is not attractive, its associations and fragrance, and the fact that it is in some districts killed to the ground by a severe frost, should make us prefer it. We know places where a bit of bay barely survives out of doors, and many others in which it has more than the freshness and vigour, if not the height, of the immense old specimens in Count Borromeo's garden on Lake Maggiore; and in the former it might be welcome grown as a terrace plant. There is certainly little to plead in favour of growing evergreens in tubs in places where they grow well, and are not frequently killed in the open air.

The Portugal laurel is frequently grown by us on terraces; and from its handsome foliage merits some attention, though we think not so much as the foregoing. This, too, occasionally gets cut down to the ground, even in mild districts; and plants in tubs should not be left exposed in very severe weather. We have seen this and other trees trained as standards and planted on a terrace, a tub being placed round the base of each, so as to make us believe that the specimens were grown in them. As it is to the effect of the head, and not of the tub, we ought to look, this is merely waste of ingenuity.

Wherever the climate permits of it, it is much wiser to grow trees in tubs that require a warmer climate than ours, rather than those that are common in our shrubberies. We believe that in many of the southern parts of this country the orange may be grown well in the open air in summer. Those who doubt that can decide the question by seeing, on some summer or early autumn day, the condition of the orange trees at Holland House, Kensington, some of which are as healthy as the best usually seen on the Continent, although they have to endure London smut, as well as atmospheric conditions by no means so favourable as occur in many parts of the south and west of England.

As a flowering-tree for tubs there is nothing to equal the oleander, which is rarely or never seen in good condition in England. On the Continent it is frequently kept in cellars and dark places, and put out in summer to flower profusely. When the specimens are old and well-grown, like those in the gardens of the Luxembourg at Paris, they are very fine. The oleander has several real claims to be grown thus. It is an exotic of an uncommon and distinct type; unlike the orange, it flowers well in the open air, and it is of the most vigorous constitution. Both it and the orange should, when placed out of doors, have as sunny and well-sheltered a position as possible, and their culture would hardly be worth attempting further north than the midlands.

Pittosporum Tobira, a deliciously sweet greenhouse evergreen shrub, lives in any dark or half-lighted place during the winter, and flowers freely in summer. It is not of growth free enough to form a terrace tree, but it deserves to be abundantly grown, and, when large, will do on terraces, in pots or tubs. Among the various other

plants that we have seen tried in this way, those that did best were *Justicia Adhatoda*, *Jasminum azoricum*, *Olea angustifolia*, and *Edvardia grandiflora*. These were all fine, and the Madeira jasmine very sweet and graceful. These, like the preceding, may be kept perfectly well in winter, sheltered by any shedlike structure, secure from frost. Those, however, having means of advancing them to the specimen stage in greenhouses would do well to take advantage of it.

MELIANTHUS MAJOR.

THIS plant requires somewhat peculiar treatment to fully show its singular and beautiful grace of foliage and habit. In a greenhouse or conservatory, where it grows freely, it usually grows too loosely, running up to the glass if planted out; and, whether planted out or not, being usually in an unclean state. The leaves, too, are flimsy when the plant is grown in-doors; in the open air they are quite firm, and withstand storms and rains well. The right course with the plant is to treat it as a hardy herbaceous one, planting it in a warm, sheltered, and sunny nook in the pleasure-ground or flower-garden, in deep, sandy, well-drained loam. It will be cut down by the winter frost, but in early summer will shoot up strongly again, and

Melianthus major (after Vilmorin).

prove throughout the summer and autumn one of the most attractive objects in the garden. Afterwards no culture or care is required, except, perhaps, in cold places, half a foot of leaf mould or ashes over the roots in winter. We have, however, known it to withstand very severe frosts about Loudon without suffering. The plant is not difficult to increase from seed, and well-established old tufts will bear careful division. In the open air we have not noticed it flowered in this country; planted out in the conservatory it flowers freely enough. The bloom, however, is not ornamental. It is when grown as a spreading bush, from 2½ to 4 feet high, that its highest effect is shown. For the above charming and life-like portrait of a specimen well-grown in the open air we are indebted to MM. Vilmorin & Co., of Paris.

THE SEA HOLLIES (ERYNGIUM).

The different species of this genus are by no means uninteresting in a botanical point of view; but they have a claim far beyond their botanical interest, every one who has seen any of them cultivated must admit. They possess many points that are essential qualifications of useful border plants. They are of a good perennial character, and there is no tendency among them to ramble in the promiscuous manner that some of even our best border plants do. They are all but independent of stakes, having, with few exceptions, sturdy stems capable of carrying their own weight, unless in very exposed situations. Their duration extends over months; the rich metallic glow which many species present lasting for many weeks; and, as a final qualification, I may add that their beauty does not cease with life, but after due maceration and all the nice little manipulations with which those who skeletonize foliage are well conversant, the leaves—but more especially the involucral bracts—form a most interesting item

in those groups, to which the very appropriate title is usually applied of, “beautiful in death.”

To begin at home, where those sort of silicified billows, in the form of great sand mounds, abound on our coasts the true Sea Holly (*Eryngium maritimum*) is to be met with, deep roofing, so deep that I have never yet succeeded in lifting the entire root, it mattered not how deep I might delve; nor is this to be wondered at, when we remember that the sand waves are accumulative and accumulating, and that the plant has, year by year, to push upwards, in order to keep its head above the fluctuating level. Dwarf in habit, rarely rising above twelve or fifteen inches, its peculiarly bluish-white foliage and stems form a nice contrast to the more lively-coloured vegetation with which it is surrounded. Although a denizen of our sea coasts, it is quite amenable to cultivation in any ordinary garden soil. The first difficulty overcome, namely, that of removal with anything like a good root, it soon establishes itself; and I may here append a remark that is applicable to every species of *Eryngium*—that they all possess deep, strong roots, devoid of many fibres, and are, hence, very impatient of removal, even where this is done with the greatest care. Such being the case, seeds or seedling plants should be secured, and, when fairly established in pots, planted in their proper positions where they are to remain in the herbaceous border.

Besides the true Sea Holly we have another species, *Eryngium campestre*, or field *Eryngio*, which may, perhaps, be still met with in one or two of its few native habitats. Similar to the former in height, it differs chiefly in its more divided leaves; and, although not to be despised as a border plant, it does not possess such well-marked distinctive characteristics as the former.

Having thus introduced to your notice our native species, I shall now offer a few descriptive remarks on those that are not indigenous, dividing the genus into three groups: the first containing species with undivided, heart-shaped, or slightly lobed leaves; the second, those with divided leaves; and the third, those with long ciliated foliage.

And first, in regard to merit in the whole family, unquestionably stands the *Eryngium alpinum*, a native of the European Alps, but not, as may be implied from its name, of a remarkably dwarf habit. Sometimes it raises its inflorescence to a height of even three feet. Its involucular leaves are of an intense blue colour, very much divided, and also of a larger size than those in any other species; herein consists its true specific character, as well as its intrinsic beauty. Another point by which it may be recognised, even in a young state, is by its long-stalked, heart-shaped leaves. I mention this fact, as there is often considerable difficulty in getting the true species. In this country it rarely matures perfect seed—hence it is not likely to become a common plant; old-established tufts, however, will bear careful division. To get good specimens they must remain some years in the same place. There is not in the whole range of herbaceous plants a more beautiful object than a finely developed plant of *Eryngium alpinum*, when the stems and floral leaves, after the summer sun, get “deeply, darkly, beautifully blue,” till they at last, in August, look as if they had been dipped in blue ink.

Botanic Gardens, Hull.

(To be continued.)

J. C. NIVEN.

Rockwork at Chatsworth.—The stupendous rockwork at Chatsworth again, always appeared to me a most monstrous waste of good honest material and labour. It is very costly and expensive; but one of the least of nature's cliffs would overshadow it utterly. Its artificiality cannot cheat one who knows what rocks are in the fissures of the hills; and he looks upon it, at best, with the same sort of foolish wonderment with which he looks upon the wooden pines of the Dutch gardens at Lisse and Gorcum.

A Russian Winter Garden and Palace of Ice.—Nowhere could the charms of a winter garden be more fully appreciated than in the midst of the snows which enwrap the landscapes of Russia during several months of the year, especially in the neighbourhood of St. Petersburg. An attempt was made in the winter of 1740 to create, with a rough kind of imperial magnificence, a winter-garden on the banks of the frozen Neva. It was determined that the chief feature of the garden should be a palace of ice, and the plan was carried out with such success and expense by Peter the Great that it was deemed “impossible.” The ice palace was built with huge blocks of ice sawn square, and trimmed just after the fashion of free-stone. Of these huge quadrates of ice the walls of the palace were entirely constructed. The building contained several spacious corridors artificially warmed, which were filled with flowering plants, constantly renewed, and also many apartments richly furnished with chairs and tables, and even fire-places, the bedrooms being very luxuriously appointed with beds and hangings. The plan of the building was as follows:—

Whether the Empress Anne, in accordance with those august whims the icy halls were constructed, ever honoured one of these sleeping-apartments by passing a night within it. It is stated, however, that she was much delighted with the appearance of the structure, both externally and internally, as also with the appearance of the hards, northern pines and other frost-defying evergreens which for a time had made the garden the scene of the most brilliant and gay sports, to the joy of snow, out of which the trees seem to grow. The grand finale became, as a matter of course, the rage—especially by night, when the palace was illuminated, which is said to have produced a most charming and fairy-like effect; a report which may be well believed, as the semi-transparent walls themselves must have emitted from the lights within a soft moon-like brightness which, blending with the light of the external festoons, and lines and stars of coloured lamps, necessarily produced a soffy dazzling effect, which, among the winter snows of Russia, must have gratified the devisers of the display.—H. N. H.

AGAVE TELEGRAPHICA.

TO THE EDITOR OF "THE GARDEN."

Caunton Manor, November 27, 1871.

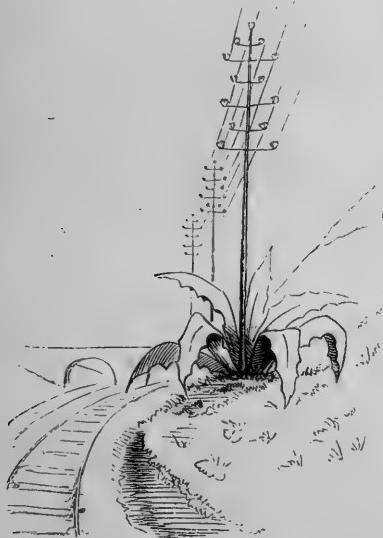

Sir,—In the spring of this year my mind was perturbed by a proposition, emanating from the postal powers, to erect a series of telegraphic poles upon the road which passes at no great distance in front of my house; and while my anxiety was at its height I received from a benevolent friend, who, as a lieutenant in the Royal Engineers, was engaged in supervising the work, the appended attempt to alleviate my sorrow. My reply was that I thought this beautiful plant would succeed best in my soil if it were "pegged down and layered," and I am thankful to say that it has been so treated.—Your obedient servant,

S. REYNOLDS HOLE.

"Cambridge, April 3, 1871.

"MY DEAR SIR,—Knowing you to be pre-eminent as a horticulturist, I beg to bring to your notice a magnificent species of the Aloe tribe (*Agave telegraphica*).

"This highly-ornamental plant flourishes best by the side of roads and on railway embankments, and I can strongly recommend it to your notice, feeling that it would succeed admirably at the edge of the high-road at the foot of your lawn, where it would be seen to great advantage from your drawing-room windows.

"A philanthropic Government is actively employed in propagating this rare and deservedly-admired plant, and should you desire to have a few specimens, I am empowered to supply you with them at the expense of the country, and to plant them in suitable situations.

"The *Agave telegraphica* is a native of Great Britain, but has been successfully acclimated in all parts of the world. It succeeds equally in all soils, and remains in flower all the year round.

"We have hitherto been unsuccessful in our endeavours to raise it from seed, but a large stock is now at the Government nursery-gardens, and the plants sustain no injury from being moved at their full growth.—Believe me, yours truly,

HERBERT Jekyll, L.R.E."

Androsace lanuginosa.—This beautiful and free-growing member of a very diminutive and slow-growing family, grows as freely as the most vigorous verbena in the College Botanic Gardens at Dublin. Doubtless, this to some extent is due to the climate. It is a plant very easily managed; all it wants is a sunny warm aspect

in sandy soil. It grows freely from cuttings and seed, which ripen in the autumn; in a suitable situation it lasts many years in the open air. When once established, it is well to peg down the trailing shoots, which root freely and soon make a nice mass; indeed, without any care, I have had plenty of young plants from rooted pieces. Cuttings should be grown without artificial heat, just under a hand-glass, with air at the top, or slightly raised at the east side. I would strongly recommend this charming plant to all those living in mild and moist districts and near the sea, as we have nothing in our gardens more beautiful for the margins of borders or for the rock-garden.—JOHN BALD, Dublin.

GARDEN STRUCTURES.

IRON versus WOOD.

THAT the days of the use of wood for hothouse purposes are numbered must be apparent to everybody, though there are in some parts of the country examples of old hothouses which appear almost indestructible, so good was the timber used, with the present style of building wooden-structures, and with the best management as to painting, &c., from twenty to thirty years appear to be the limit of their endurance without a thorough repairing. Houses in nurseries afford the best examples of the evil, and if any person whose memory will carry him back thirty years will call to mind houses built about that time he will find many of them irreparably decayed and all on the "road to ruin."

Six years ago an amateur friend put up a large orchard-house, contracting for the woodwork and finding the glass himself. The wood was yellow deal of sufficient scantling; but though the house has received six coats of paint in the interval, the feet of some of the rafters and most of the sash-bars have rotted off, and the putty has crumbled away so that the roof "rains in like a sieve." To put this house into working order next spring will cost at least £20, as every square of glass must be taken out, not a difficult matter by the way, and both rafters and sash-bars will have to be spliced. Bad as much of the timber now used really is, the putty and paint, if possible, are worse. Upon old houses you may find putty as hard as cast-iron; but that was the produce of manual labour, when whiting, red-lead, and linseed-oil were the ingredients used, well incorporated by a mallet and hand kneading. Now the refinement of invention has given us mills to grind putty in; and instead of the antiquated notion of wasting oil and red-lead, the whitening is ground principally in water, and with the most inferior oil, and consequently never becomes hard.

A short time back we had occasion to cover up during severe frost some recently glazed cold-pits, using wheat straw for the purpose, with tarpauling over it. The straw contained a little corn, that attracted a shoal of mice, but when it was exhausted they attacked the putty, so that it was stripped off for yards together. We complained to the builder, one of the most respectable in the trade, but he gravely informed us that "putty ought not to get hard," and, sure enough, it does not. We have unfortunately, in these adulterating days "shoddy" in everything, and that which we have just described is the shoddy system of horticultural building. On the one hand, in our mind's eye, we look to houses not built ten years unmistakably decaying; on the other we can go back to houses built of iron and copper half a century ago, which are still good for another half century to come. Look at the iron houses at Sion House, two or three in the gardens of the Royal Horticultural Society at Chiswick, those at the Royal gardens at Frogmore, and though they have done good service, they will stand good for many years to come. But there is a good deal of what may be called "shoddy" even in some of the metallic houses; as those made of zinc are scarcely better than wood, while rolled or pressed sheet-iron is infinitely worse than either, and a combination of iron and wood inferior to both separately. But what matters that? such structures will be preferred by many, because they are cheaper than really superior buildings, which though but little dearer in the first cost would stand for centuries.

Now, what are the objections to iron for hothouse work? First, its expansive and contractive properties under varying atmospheric changes; and, secondly, its superior conducting properties for either heat or woe. The expansion, so far as the fracture of horticultural buildings is concerned, is more imaginary than real; for though on a scorching hot day we have sometimes found sashes and doors difficult to move—while they would be equally loose on a cold, frosty night—we have never, in a fifty years' experience, seen a fracture in the iron work, either from expansion or contraction. The action of these upon the glass is, however, a different matter. If the glass is glazed at all tightly, and the putty used is good, on a frosty night the iron contracts, and the tight square is crushed into pieces; while,

on the contrary, on a hot day, if the putty is what it ought to be, the tight square is rent in twain by the expansion of the iron. To avoid these causes of breakage you glaze loosely, the iron expands, and the glass falls out; or, possibly, the putty cracks, the water follows, and "drip" is inevitable. We speak in these cases from actual experience, which leaves us to regard putty and drip as inseparable companions. The expansive putty, brought out a year or two back, and with which the grand station of the Midland Railway Company was glazed, is, we fear, little better than that in general use; for, on several occasions recently we have seen upon the platform unmistakable evidence of drip, though it was not raining at the time, while the roof of the St. Pancras Station is a specimen of rents and patches.

Felt and india-rubber have both been tried as a remedy for some years past, but drip, drip, drip, constitutes the complaints against them; while the non-conducting influence of the materials used is nil. Passing, then, to the conducting properties of iron, that cannot be denied; and the remedy for it appears to be to use no more iron than is absolutely necessary, and to expose as little of that to the direct action of the atmosphere as possible.

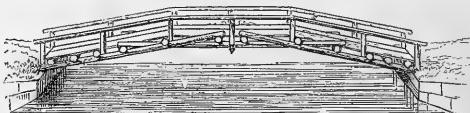

In the house which was exhibited by the Imperishable Hothouse Company at the Nottingham show of the Royal Horticultural Society, this end was attained with, perhaps, greater success than that which attends most other systems of construction; for, the inventor in this case, not only limits the iron used to the necessary quantity without waste, but, as far as possible, covers that which he does use with glass, by which its expansive, as well as conducting properties, are, in some measure, nullified. In this new system of glazing, in short, the glass forms the outer coat of the house, like the slates of a roof; a plan having many good points.

Bromley, Kent.

P. G.

A RUSTIC BRIDGE WITHOUT NAILS.

At the International Horticultural Exhibition, St. Petersburg, in 1869, I saw an ingenious method of making a rustic bridge. In addition to its rustic and truly picturesque appearance, it possesses the singularity of being put together without a single nail, bolt, or mortice, the whole structure being supported by the beams being made to cross each other in a peculiar manner. [It is needless to ex-

plain this arrangement, as a glance at the accompanying illustration will be sufficient to show how it is effected. I strongly recommend country gentlemen to copy this simple mode of bridge-making, and I can testify to its fitness for garden scenes.

E. ANDRE, in "*l'Illustration Horticole*."

THE ARBORETUM.

THE WILLOW AS A TIMBER TREE.

THE old adage, "give a dog a bad name and hang him," never had a more apposite application than in the case of the willow. Gilpin (once looked upon as an authority on forest trees) asserted that the willow did not harmonize well with British timber-trees; and succeeding writers have reiterated the statement without examining its accuracy. There is a saying that a willow-tree would buy a horse before an ash tree would buy a saddle, an assertion fully borne out in this case by experience. The common pollard willow, dotted along the margins of streams is such a well-known and ungraceful-looking tree that somewhat unconsciously we have got a bad opinion of willows as objects in a landscape—but mutilate our stately oaks, ashes, or beeches in the same way, and where would their beauty be? The willow has never received fair treatment as a forest tree, simply because it will bear more ill-use than any other tree. Few people have ever seen a willow plantation in its prime, say after having been forty years planted and properly cared for; those who have seen such a plantation will not readily forget its beauty, any more than the owner can forget its profit. The willow, when in perfection, is "a thing of beauty"; and those who have possessed well-grown specimens

of it have seldom cared to have them cut down until decay had set in, and the willow soon decays after reaching maturity. To speak in trading phraseology, it is a tree which brings a quick return for invested capital.

Lowe, in his survey of the county of Nottingham, states that so very valuable are willows as plantation trees that at eight years' growth they yield in poles a net profit of £214 per acre, and in two years more he states that they would probably have £300 per acre. In page 1520 of Loudon's "*Arboretum Britannicum*" it is stated that a cutting planted by Mr. Brown, of Hethererset, Norfolk, became in ten years a tree of thirty-five feet in height and five feet in girth; and in the same work a tree is mentioned at Audley End, Essex, of twenty years' growth, which was fifty-three feet high and seven feet six inches in girth. I, myself, saw six trees felled in 1869, near Southwell, Notts, which, after thirty-eight years' growth, unitedly yielded 232 feet of measurable timber, which sold on the spot for 1s. 2d. per foot; and the six trees did not occupy more than eighteen square yards of land.

To grow willow trees in perfection they must be planted closely, say three feet apart each way, or 4,840 to the acre would not be too close for the first eight, or nine years, when they might be thinned out to half that number. The thinnings would find a ready sale for general farm purposes. At the end of sixteen or twenty years they might be reduced to 1,210 trees, or six feet apart each way, which would generally afford ample space for their full development. The time to fell such a plantation must depend very much upon circumstances. No unvarying rule can be laid down, but it is better to cut too early than to allow them to stand too long; for, as before stated, when the willow has reached its best it speedily decays. Its duration may be said to range from thirty to fifty years; but whenever dead branches begin to show themselves there should be no delay in cutting down. In felling willows do not think of leaving a few selected trees in the hope of obtaining larger timber, for after having been so crowded and then suddenly exposed they would almost invariably perish. If heavier timber is desired, plant more openly at the first.

I will now endeavour to arrive at an approximate value of an acre of such timber at its prime, say after having been planted, forty years. There is plenty of evidence to show that it is not an uncommon thing for a willow-tree at thirty years of age to yield forty-five feet of measurable timber, or at the rate of $1\frac{1}{2}$ cubic foot per annum. The experiments of the Duke of Bedford and others proved this to be the case. I will not, however, reckon, upon such great results, and will further assume that 110 trees out of our 1,210 are worthless, being a much greater margin than would be probable, and that in forty years we only produce one-third of the above, or half a foot instead of a foot and a half per annum. We shall then have 1,100 trees, containing an average of twenty cubic feet each, or 22,000 feet, worth, at the lowest computation, 1s. per foot, or £1,100, the produce of an acre of such wood in forty years, leaving the two thinnings to cover the cost of labour, which would be more than sufficient for that purpose. This is no fanciful calculation, but one fully borne out by the experiments of men whose words cannot be doubted. It cannot, however, be too often repeated that the willow will not arrive at perfection in swampy, undrained land. Willows grow freely on the slopes or tops of exposed hills; indeed, there are few situations in which they will not grow, but in no place so badly as in water-logged land. For timber trees the *Salix fragilis*, or some of its kindred varieties, of which there are not fewer than twenty or thirty under cultivation, should only be employed, some of the lately introduced varieties being not only vigorous growers but extremely beautiful. It must also be borne in mind that all willows grow more vigorously from cuttings than from rooted plants; and, therefore, rooted plants only should be employed when immediate effect is desired.

It may be asked to what use is willow-timber put when grown, and where would a market be found for it? There is no wood in greater demand than sound willow; it is light, smooth, soft, tough, will take a good polish, and does not easily burn. It will bear more pounding and hard knocks without splinter or injury than any known wood, and hence it is used for cricket-bats, and, whenever it can be obtained, for the floats of paddle steamers, "strouds" of water-wheels, break-

blocks for luggage and coal trucks, the sides and bottoms of carts and barrows, where wear and tear are greatest. To the wood-turner it is almost invaluable, and were it grown as timber, and obtainable, it would be used for very many purposes to which foreign timber is now applied, and that, too, with considerable advantage both to producer and consumer.

WITHY.

CULTURE OF FOREST TREES.

A FINE and well-developed forest tree, be it oak or elm, beech or chestnut, is a possession often thought beyond price by its fortunate owner; yet who thinks of creating such a specimen by means of culture commonly applied to things of more ephemeral interest? We devote our utmost skill to the management of fruit trees, but we plant our forest trees without bestowing other labour or expense than that involved in making a hole in which the young tree is thrust; and if the soil is free from stagnant water, and possesses the mineral constituents of fertility, the tree thrives, and in due season becomes an object which we may admire for the grandeur of its proportions, or utilise for many economical purposes; but if the land be poor, or, as is often the case, already exhausted by the growth of timber upon it, the tree makes slow growth, and in its maturity only exhibits a half-developed, decrepid specimen, but little satisfactory to its owner and an object of small commercial value. Exceptionally fine timber is thus very much the result of a chosen combination of suitable materials, & elements, in the soil in which the trees have been placed; but the composition surely of such colossal oaks as we find, for example, in Lord Bagot's park in Staffordshire, proves that it is seldom that the mineral constituents of a soil are so happily combined, and so far disintegrated and decomposed, as to be available for the support of trees for the centuries during which they build up their massive fabrics by a wonderful process of elaboration, largely sustained by the great inorganic storehouse beneath them. It will be readily seen that the practice I wish to inculcate has necessarily a limited application. Where planting is pursued extensively, however advantageous the employment of any inorganic elements deficient in the land on which trees are to be planted might be, the expense attending the preparation of the land and their application would be incommensurate with the possible gain in timber; but when fine trees are wanted to adorn a park or to embellish the lawn of a mansion, then I would certainly advise that adequate preparation should be made. As a general rule the employment of rich organic manures is undesirable, luxuriance of growth is induced, a mere dressing of humus is soon exhausted, and ultimately trees suffer for a few years from the loss of that pabulum on which they first fed and depended. The noble specimens of coniferous trees at Dropmore are examples of the good results that proceed from a judicious preparation of compost for forest trees. The Panshanger Oak is another instance, although the preparation of the soil was rather accidental than designed. We find in different parts of the country grand trees that have attained an altitude above their competitors, a bulk in massive timber surpassing the dimensions of ordinary trees, whose branches, flung out far and wide, are themselves equal to the attenuated trees in a thick growing wood. The Beggar's Oak in Lord Bagot's park is a notable instance of majestic grandeur in a tree. The great beech at Buckhurst Park, Kent, though beyond its prime is still a noble tree.

Such trees are not only objects in which their owners feel a just pride, but they are regarded throughout a wide district as conferring a distinction on it, and are visited and admired by thousands of people great and small.

Belvoir.

W. INGRAM.

AMONG THE BIG TREES IN CALIFORNIA.

The passage of the great American desert which is crossed on the way from New York to San Francisco is, perhaps, the best preparation one could have for the startling verdure and giant tree-life of the Sierras. Dust, dreariness, alkali—the earth looking as if sprinkled with salt; here and there a few tufts of brown grass in favoured places; but generally nothing better than starved wormwood, that seems afraid to put forth

more than a few small, grey leaves, represents the vegetable kingdom in the plains of the desert region. Where the arid hills—worn with horizontal lines by the waves of long-dried seas—are visible, a few thin tufts of alders and poplars mark their hollows; while willows fringe the streams of undrinkable water which course through the valleys. A better idea of the country can scarcely be had than by imagining an ash-pit several hundred miles across, in which a few light-grey weeds, scarcely distinguishable from the parched earth, had sprung up, regardless of drought.

As the train ascends the Sierra, there are long covered sheds, which guard it from the snow in winter—dark-ribbed tunnels. Dawn broke upon us as we were passing through these; and, looking out, we saw such a change from the Salt Lake scenery as one experiences in passing from a hot dusty road to a cool, green, ferny dell. Dust and alkali, dreariness, harshness of arid rock and hopelessness of barren soil, are seen no more. Near at hand a giant pine rushes up like a huge mast, while in the distance they are grouped in stately armies of tree grenadiers, filling the deep valleys and cresting all the wave-like hills till these are lost in the distant blue.

On the very summit of the Sierra Nevada the vegetation is not luxuriant; there, as elsewhere on high mountain chains, is the frost that burns and the wind that shears. When you see a solitary pine that has been bold enough to plant itself among the boulders and rocks of the high summits, it is usually so contorted that it looks as if inhabited by demons; while here one has succumbed to the enemy, and you see a few blanched branches sticking from a great, dead, barkless base, lapped over the earthless granite. But go a little lower down, and most probably you will find a noble group of *Picea*, starting from the size and height of the trunk, though looking much tortured about the head by the winds that surge across these summits—the mast-heads of the continent. Snow falls early and falls deep on the Sierras, and the roots of the higher trees are often covered with it to a depth of from six to twenty-five feet. Near the rail, and near frequented places, thick stumps of pines, six to fifteen feet high, may be noticed; these are the trees cut down when the snow is high and thick and firm about the lower part of their stems. But if the nights are bitterly cold, the sun is strong in the blue sky far into the winter months, so that the snow is melted off the tree tops, and the leaves of the pines live, in golden light, long into the winter. All the pines that grow near the summit must resist the most piercing cold.

The golden light of the sky and the blue of its depths, and the purity of the fresh mantle of snow, are not more lovely in their way than the robe of rich yellow lichen with which the stems and branches of the pines are clothed. Imagine a dense coat of golden fur, three inches deep, clothing the bole of a noble tree for a length of one hundred feet, and then running out over all the branches, even to the small dead twigs, and smothering them in deep fringes of gold, and some idea may be formed of the glorious effect of this lichen (*Evernia*). It is the ornament of the mountain trees only; in the valleys and foot hills I did not notice it.

To the flanks of the western slopes of the great chain of the Sierras one must go to see the noblest trees and the richest verdure. There every one of thousands of mountain gorges, and the pleasant and varied passes of every vale that runs with its streams and rivers, and from top to bottom of every one of the innumerable hills, is densely populated, with noble pines and glossy evergreens—an ocean of huge land waves, over which the spirit of tree-life has passed, creating giants. The autumn days I spent among these trees were among the happiest man could desire. Every day a glorious sunshine, and the breeze as gentle as if it feared to hurt the long-dead trees standing here and there leafless and, perhaps, barkless, but still pointing as proudly to the zenith as their living brothers. Wander away from the little dusty roads, crossing, perhaps, a few long and straight banks of grass and loose earth—dead monarchs of the wood, now rendered back to the dust from which they once gathered so much beauty and strength—and fancy willingly reminds us of the mast-groves of the Brobdingnags, quite cut away from little worlds and little people. There is little animal life visible, with the exception of a variety of squirrel, ranging from the size of a

mouse to that of a large ferret, the graceful Californian quail, and occasionally a hare or a skunk. Everywhere vegetation is supreme, and in some parts higher effects are seen than is the case in the most carefully-planted park or pleasure-ground in the most favoured climate. This results not more from the stately pines (not often crowded together as in the eastern States, but with perfect room for development, and often near the crest of a knoll, standing so that each tall tree stands clear against the sky) than from the rich undergrowth of evergreens with larger leaves that form a smaller picturesque forest beneath the tall trees. Grand as are the pines and cedars (*Libocedrus*), one is glad they do not monopolize the woods; the evergreen oaks are glossy, and form such handsome low trees. One with large shining leaves, yellowish beneath, and long acorns sitting in thick cups, covered with a dense and brilliant fringe of fur, was the most beautiful oak I ever saw; but most of the evergreen oaks of California, whether of the plains or hills, are very ornamental trees. One day, in a deep valley darkened by the shade of giant specimens of the *Libocedrus*, I was astonished to see an *Arbutus*, about sixty feet high, and quite a forest tree. This is Monzies' *Arbutus*, commonly known by the old Mexican name of the "madrona"; and a very handsome tree it is, with a cinnamon-red stem and branches. Here and there, too, the Californian laurel (*Oreodaphne*) forms laurel-like bushes, and tends to give a glossy, evergreen character to the vegetation. Shrubs abound, the manzanita (*Arctostaphylos glauca*) and the Ceanothuses being usually predominant; while beneath these and all over the bare ground are the dried stems of the numerous handsome bulbs and brilliant annual flowers, that make the now dry earth a living carpet of stars and bells of joyous hues.

Those who have not visited the high lands of California can have no idea of the size and majesty of the trees. It is a mistake to suppose the *Sequoia* (*Wellingtonia*) is such a giant among them; several grow nearly or quite as high, and it is very likely that in such a climate all the pines known in gardens would attain extraordinary dimensions. There was a small saw-mill near where I stopped for some days, and several yokes of oxen were always occupied in dragging pine logs to it. The owner never thought of bringing anything smaller to this than a log three or four feet in diameter in its smallest part, and usually left one hundred feet or so of the portion of the tree above this on the ground where it fell, as useless. At a future time we may have the pleasure of speaking of some of the big trees individually, and conclude now by asking what it is that causes the tree-growth to be so noble there. There can be no doubt that the climate is almost the sole cause. Soil has very little to do with it. I have frequently noticed the trees luxuriantly where there was not a particle of what we call soil, and, indeed, in places where twenty-five feet or so of the whole surface of the earth had been washed away by the gold-miners. A bright sun for nearly the whole year and a sufficiency of moisture from the Pacific explains the matter. This should draw our attention to the fact that, in ornamental planting, and especially in the planting of coniferous trees, we pay far too much attention to supplying them with rich and deep soil and far too little consideration to the capabilities of the climate in which we have to plant.

CONDUCTOR.

BASE OF THE GRIZZLY GIANT IN THE MARIPOSA GROVE.

It is impossible to contemplate this vast trunk, painted by the unerring pencil of the sun, without falling into a train of reflections on the vastness of its dimensions and the far-stretching period of time during which it has stood in its solemn grandeur; while nations, and even their histories, have passed away. This towering monument of the mightiest kind of vegetation has towered aloft in its native valley on the Sierra Nevada some two thousand years or more; the age-rings of its younger congeners having been counted up to thirteen or fourteen hundred. The Grizzly Giant, therefore, may possibly have been a living entity even before the Great Roman Republic had reached its zenith, and while its rival, Carthage, was still a power to be dreaded; and the energetic Cato, in hope rather than conviction, was thundering in the Senate, "Delecta est Carthago." It was still growing when the great Republic was drifting into the Empire, and when the great first Caesar fell at

the feet of Pompey's statue; and still growing, "ohne hast, ohne rast," when Augustus donned the imperial purple, and Virgil and Horace poured forth their classic strains to adorn and immortalize his reign. The "big tree" went on increasing in strength and stature while all the line of emperors who succeeded the first came and went—mere short-lived pygmies in comparison to this tree-giant of the Californian woods—ever towering upwards, and growing in magnificence, while Fliny was cataloguing and describing the noblest trees of the Old World, utterly ignorant that they were dwarfed beyond compare by a far-off forest lord, standing in unrivalled grandeur of growth, in an unheard-of ravine in an unheard-of land.

For long centuries afterwards, the Grizzly Giant of the Mariposa Grove still remained a secret to the botanists of the then civilized world, and none were able to divulge the secret of its being, for the best of all reasons—that none knew it. Extraordinary as it may seem, too, it was not till 250 years after the discovery of the great western continent by Columbus, that the secret of its existence was discovered, and that one of the greatest wonders of the vegetable world suddenly became known to European science. Indeed, without the accidental discovery of Californian gold, which filled the land with explorers from all parts of the world, the wonders of her forests, valleys, and mountains, might have remained unrevealed for still another century.

It is pleasant to note in concluding this brief notice of one of the biggest of the "big trees," as they are popularly called in California, that Mr. Watkins, of San Francisco, the successful photographer of the Grizzly Giant and many other noble objects in the wonderland of the Sierra Nevada, has been substantially honoured and immortalized by the bestowal of his name on Mount Watkins, one of the loftiest of the grand masses that overtop the striking scenery of the Yosemite Valley. The circumference of the Grizzly Giant is 90 feet 7 inches near the ground, and 64 feet 3 inches at eleven feet above. The figure in the engraving standing at the base, to define the scale, is Galen Clark, a well-known Californian forester, a man some inches over six feet, and stout in proportion. The Grizzly Giant is one of the nobles of the *Sequoias* (*Wellingtonias*) in a grove of those enormous trees known as the Mariposa Grove, in the Sierra Nevada. H. N. H.

[The illustration on the opposite page has been drawn by Mr. Noel Humphreys from a photograph by Watkins, of San Francisco, and engraved by William Hooper.]

NOTES AND QUESTIONS ON TREES AND SHRUBS.

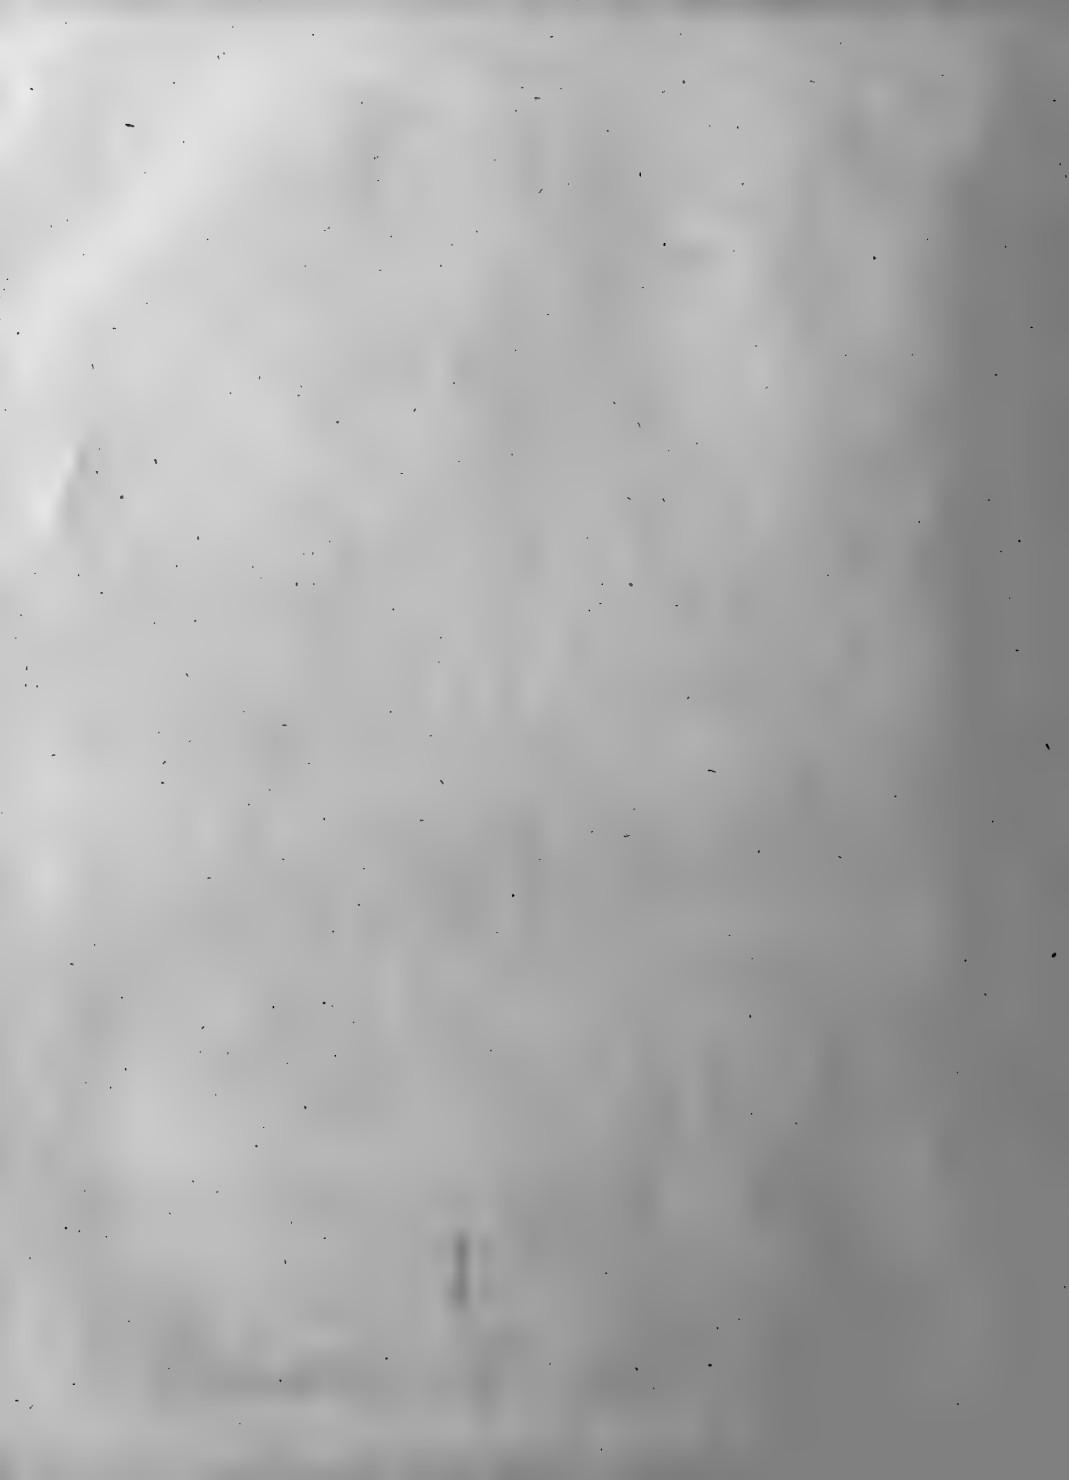

The New Forest.—Notice has been given by the Commissioners of Woods and Forests of an intended application to Parliament during the coming session for a Bill dealing with the disafforestation of this Forest. The notice is the same as in effect as was given about the time last year.

Planting Conifers.—The chief difficulty in this matter is, that in almost every instance we plant much too close, and at equal distances apart. I would not plant any nearer each other than fifty feet, and they should be the spruce, and others of a pyramidal form. The more robust and spreading kinds I would plant from eighty to three hundred feet apart, excepting in some few instances. My plan would be to group a few of the most handsome growths distinctly by themselves, and scatter a few of the same kinds at considerable distances. Pines, in general, as slow planted, will in a few years become mere pyramids, which would be easily lost. I could have planted all the trees here as I wished, and there would have been no crowding; but I had little or no control in the matter until of late years, when the civil had become too apparent to be concealed; for where too thick, they soon began to sap each other. There is another thing that particularly requires attention, and that is: whenever a tree begins to form two or more leaders, the contending ones should be removed, as soon as possible—the sooner the better. This sort of pruning is here more than a hundred feet high with one stem. This would have been found eight feet from the ground if I had not noticed it. When Conifers become forked, their beauty, I consider, is gone. This evil is bad enough in a plantation, but wretched in the case of a single tree.—Philip Frost, Drymore.

Planting Trees.—Many persons, when recommended to plant, reply: "Of what use is it to plant at my age?" I can never hope to see my plants become trees. This sort of answer does not at first sight appear surprising, we suppose, because of a person's age or foolishness of opinion. What we often hear it even from men of forty or forty-five. In either case such an answer is the result of a vulgar error founded on misapplied and prejudiced notions. We shall prove its incorrectness by matters of fact. In the year 1830 there were many sorts of trees in the arboretum of Messrs. Loddiges which had been planted exactly ten years, and each of which exceeded thirty feet in height. There are also at the present time (December 1834) many trees in the Society's Garden at Chiswick which have been only ten years planted, and which, though not equal in size to those above mentioned, are nevertheless of a similar age, and will, in course of time, attain a similar size. We may, therefore, at any age, assign as a reason for declining planting that he cannot hope to live to see his plants become trees? A tree thirty feet high, practically speaking, will affect all the general purposes for which trees are planted; it will afford shelter and shade, display individual beauty and character, and confer expression on landscape scenery.—LONDON.

BASE OF THE GRIZZLY GIANT (33 FEET IN DIAMETER), IN THE MARIPOSA GROVE.

INSECTS, BIRDS, DESTRUCTIVE ANIMALS, &c.

HURTFUL INSECTS.

We wish it were in our power, by a single short definition, to give our readers the means of distinguishing between hurtful and innocuous insects. But it is not possible. In mammals, we can tell by the teeth whether any species is carnivorous or herbivorous; and at first sight it would appear that we should be able to do the same with insects by the parts of the mouth. If herbivorous, we should set them down as hurtful; while those that are carnivorous must be regarded as our friends, for they principally feed on vegetable-devouring insects. Many difficulties, however, stand in the way of our determining which belong to one class and which to the other. There is first the different stages through which insects pass. Many of our foes, like moths or butterflies, may be very destructive in their grub or caterpillar state, and perfectly harmless in their perfect condition. Then, many of our friends, like the ichneumons, only serve us in the dark. They are parasitic in their larval state, living in and consuming the inside of our grub foes; and in their perfect state having nothing in their structure to show that they can injure other insects. Other classes, such as beetles, locusts, &c., have the same habits and structure both in their larval and perfect states, and these are the only ones which furnish, by their structure, during either period, a guide to their functions during both. Yet, again, supposing we were to restrict ourselves to insects of this kind, and to try to separate the carnivorous from the vegetable feeders, all we could do would be to separate those furnished with means of offence from those not provided with them, that is, the raptorial from the non-raptorial; but the latter are not all vegetable feeders. A large proportion of beetles in that category are carnivorous or omnivorous, only the flesh they eat is not living—but dead; they are, in fact, scavengers, and, as such, our excellent good friends. But it is not easy to separate even the raptorial from the non-raptorial.

The chief characters which any one would select as indicative of a raptorial life, would be keen sight or scent, to enable the insect to detect its prey; speed, to pursue and overtake it; and powerful weapons of offence, to kill and rend it in pieces; in other words, large eyes or antennæ, powerful wings or long legs, and strong mandibles. These are indeed possessed by most hunting insects; but, at first sight at least, not alone by them. The locust, for instance, which is not a hunting insect, has large wings and powerful leaping legs, and its eyes are not small, nor its mandibles weak. That is an instance of a vegetable feeder with a structure which appears to have all the characters of a predacious insect. We say *appears* to have them, for on careful study of the structure of each of its organs we shall find that their adaptation is only apparent and not real; in fact, they are not suited to a predacious life, but only to that which the locust follows. The eye, although actually large, will be found to be only very moderately so when compared with the size of the head, and the facets of which it is composed are extremely minute. Although the eye is perhaps not a fourth of the size of the eye of the rapacious dragon-fly, it has probably as many or even more facets, that is, eye-tubes (an infinite congeries of which go to make up the eye). Now, it is a fair and legitimate inference that the size of the facet regulates the power of vision. The dragon-fly carries, what we may compare to a supply of Ross's telescopes, while the locust has only a battery of tiny opera-glasses. So the mandibles of the locust, although large, strong, and solid, are short, blunt, and buried in the mouth—admirably adapted for browsing—but not for seizing; and the wings, although broad and large, are not long, and scarcely large in comparison with the size of its body. The wings of many raptorial beetles are twice the length of the body, while those of the locust are less than its own length. Everyone knows that it is length of wing and not breadth that gives speed, consequently the flight of the locust is slow, lumbering, and not sustained, the creature constantly dropping down and starting again. And, finally, the legs are like those of the kangaroo, the anterior being small and weak, and the posterior only adapted for great leaps; a mode of progression better

adapted for escape than attack. So will it, on examination, be found with all vegetable-feeding insects which appear to bear weapons of offence. The stag-beetle has great mandibles, but they are not adapted for cutting. Many of the timber-borers have the most wonderful cutting implements. We have seen a leaden gas-pipe which had been actually cut through by the mandibles of a longicorn, in Rio Janiero; but the position of the powerful mandibles is not adapted for attack; they are either directed downwards and towards the breast, or in some other way better suited for the cutting of wood than seizing and tearing a prey.

But supposing us to be capable of intuitively seizing and rightly appreciating the value and purpose of each organ (which seems too much to expect from any un-practised mind or eye), and so classing every insect either as endowed with a predacious organism or not, we are not yet done with our difficulties. Paradoxical exceptions, which could only be likened to the occurrence of herbivorous-carnivora or carnivorous-herbivora, from time to time meet us; and although they are not very frequent, still one can never say *a priori* whether or when they will occur, and of course they throw a shade of uncertainty on all deductions. Thus one of the chief carnivorous tribes of beetles (the Carabidae), which possess every true character of predacious insects, contains within it a species called Zabrus gibbus, which has been found in its larval state to be most destructive to young wheat, climbing up the stalks and eating the heads of the shoots. Then among the small Hymenoptera, some of the Chalcididae which are so useful as internal parasites in destroying grubs of moths and butterflies, do not attack insects but plants. It is one of these (the Megastigmus pini) which has rendered abortive so many of the attempts made by collectors to send home good seed of the *Picea nobilis* from California.

We could give other instances of these anomalies, but we imagine we have said enough to satisfy our readers that there is no royal road by which to learn to distinguish between insect friends and foes. Nothing but experience will do it satisfactorily. Still, something may be affirmed in a general way, subject to the qualifications, doubts, and exceptions we have just indicated. Thus, all moths and butterflies may be regarded as enemies. In the larval state they all feed upon vegetables or matter of use to man. Most of the four-winged flies (Hymenoptera), deducting wasps, hornets, &c., are friends. Dragon-flies are friends. They are the eagles and hawks of the insect world. Locusts, grasshoppers, &c., are enemies. The two-winged flies are a family divided among themselves. Some being, like the ichneumons, parasitic on the grubs of other insects, but probably a still larger proportion, in some way or other, are hostile; some are annoying and injurious to our cattle, and others destructive to our vegetables and our food. Beetles are a mixed host. All the weevils (Curculionidae), slow-moving beetles, with long snouts, are vegetable feeders. The click beetles and their allies, are wire-worms or are timber-feeders. Those with very long antennæ (long horns as they are commonly called) are timber-borers. Those with little clubs or knobs at the end of their antennæ, are scavengers, and consequently, friends; but these must not be confounded with another tribe of clumsy, lumpy beetles, with a few small leaves placed at right angles to the end of the antennæ. These are the cockchafers, which, it is unnecessary to say, are formidable enemies. The lady-birds are friends, feeding on the green-fly. A group of them, differing in having velvety instead of shining backs, are vegetable feeders, but they occur only in small numbers in this country. The group known as Devil's coach-horses, long black earwig-looking things (Staphylinidae), are friends, either carnivorous or scavengers. And lastly, the black beetles (Carabidae)—not the black beetles of our kitchens, which are cockroaches, and although scavengers, generally regarded more as foes than friends, but the hard, black, or metallic-looking beetles, which the gardener often finds under stones, or clods, or running about preying upon other insects—these are good friends, to be cherished and protected accordingly.

In our next we shall proceed to details, following no particular order, but presenting, as may be most convenient for us, the life-history of those species from the attacks of which cultivators chiefly suffer.

A. MURRAY.

NOTES AND QUESTIONS ON INSECTS, BIRDS, ETC.

A Good Precaution against the Turnip Fly.—Turnip culture in this district is conducted invariably upon the ridge system; and the only means I use to secure a crop, in spite of the fly, is to supply that pest abundantly with its favourite food—the white turnip. This I manage to do by having a third canister fitted on the centre of my turnip drill, and the seed intended for the fly—very fresh white seed—is deposited upon the ground between the crop-bearing rows, being arranged up and down each row, and displaced by the coulter, and, being slightly covered, vernalizes earlier than the crop. Even when the crop consists of white turnips, it has been only slightly damaged the extra quantity of food supplied to the insect having rendered its ravages comparatively harmless.—*Ex de T.*

Picea nobilis destroyed by Larvae.—Some time since a very fine specimen of *Picea nobilis*, which was then apparently healthy, suddenly died, and on examination I found the trunk from the ground to within six feet of the top, completely honeycombed by the larvae of the goat-moth. The tree has lately been cut down, and a portion of the bark with all the hollowed-out pieces no less than thirty grub-holes were taken out, so that the whole tree probably contained two hundred at least. None of the other trees have been touched, but the ravages seem to be entirely confined to this one tree.—*S., in Field's*. [This is the first instance we have met with of the goat-moth attacking conifers. As neither it nor the *Picea nobilis* are easily mistaken, we must assume the fact to have been as stated; but it would have been more satisfactory had the writer afforded the means of verifying his statement, or at any rate, an account. In default of that we should like to know whether any of our readers have ever met with a similar occurrence.]

Insect-Killing Plants.—An Adelaide paper has recommended the planting of Larkspur for attracting and destroying such grasshoppers as partook of it, a circumstance which has induced me to say that for these thirty years past I have read both here and in America that planting Hemp where Cabbages were growing would prevent caterpillars from infesting the crop. I therefore planted a row of Hemp every four or five years in Cabbages this year, but owing to the lateness of the season found no caterpillars there. My Hemp grew seven feet high, and, at last, butterscotch did come, and caterpillars were to be seen where I knew before; but even where a stalk of the Hemp had fallen right across a Cabbage plant, it in no wise prevented the ravages of the caterpillars, and the result was the destruction of the whole crop. So much for Hemp as an insect-destroyer: I hope the Larkspur may not prove equally ineffective. I have been told that white drinck and powder acts as a household vermin destroyer.—*Jas. Senn.* [We are inclined to let the Larkspur stand, but as it turned out so well against the Hemp, we know of no well-authenticated instance where any insect has been injured by feeding on a poisonous plant. We have received specimens (pulled in life, and sent home in spirits) of the Oriental Bean of Old Calabar, with the caterpillar of a moth feeding on it. At the same time it would be most unphilosophical to reject any recommendation without examination merely because it seems absurd in one's eyes. So far the Larkspur recipe has in its favour, that one of its best qualities, however, has been found to effect against the Gooseberry and Cabbage caterpillars, but then we cannot compare the effects of an extract or powder made from a plant with its effect when living. The Hellebore is in powder. The insect-killing powder is the dried pollen of a species of Pyrethrum, and thus we are without any parallel to warrant us in believing in the virtues either of living Larkspur or living Hemp, Hellebore or Pyrethrum.]

THE IN-DOOR-GARDEN.

OLD STUMPS OF TREE FERNS.

TREE-FERN stems must be included among subjects that are as useful dead as alive. Great numbers of tree ferns are imported from the Antipodes, and a very large percentage of them perish on the way, while others die so before they can be established in this country. At first these old and dead stems were kept as objects of curiosity, or sometimes thrown on one side as useless; but, as the illustration shows, no objects are capable of being more gracefully used, either in the stove, greenhouse, or hot or cold fernery. The rigid, enduring, yet open and moisture-retaining texture of the dead stem, renders it an admirable support for other ferns. By placing a stemless fern on the top of it we get the effect of a young tree fern, while tiny seedling ferns of various kinds and sizes often spring spontaneously from the moist surface of the old stem. In planting ferns on these stumps, the first thing to do is to obtain pieces of the required height and size. The tree ferns usually imported are very tall; and as it is impossible to establish a new crest on an old and dead stem nearly equal in size to what its own had been, it is best to cut the stems into two or more parts, and to select portions from fifteen to twenty-four inches high. On stumps of that size we can establish crests in proportion to their height; and this is also about the size that can be most agreeably examined when placed on the bench of a fernery or stove, and also the most convenient for removal. Having chosen the stump, the next thing is to place it firmly in a pot. Its base should be cut level, placed on the drainage, and padded round firmly with turfy peat, silver sand, chopped moss, &c., or whatever mixture may be thought most congenial to the plants it is desired to establish. Previously to being placed in position the top ought to be cut level, and then scooped down for two or three inches, so as to permit of placing a little suitable soil in the hollow. If the stump be a thick one, and selected to support large-growing ferns like *Lomaria gibba*, the centre may be gouged more deeply; but numbers of ferns will thrive in a very shallow concavity. The stump should be in proportion to the size of the fern it has to bear, the most vigorous kinds being placed on the largest stumps as a matter of course. The fern is planted on the apex in the ordinary way, a young, thriving plant

being selected; if a creeping fern, one or more bits of the rooting stem might be pegged down on the apex, and they will soon begin to crawl over it and down the sides.

This plan of growing ferns would be very attractive if even we could only establish one kind on the crest of each stump; but we may have a variety of interesting and graceful, if smaller, seedling ferns cropping out from the stem beneath the crest, and a varied and vigorous crop springing from the surface of the pot in which the stump is placed. Thus there are three distinct ways of cultivating ferns in the case of each portion of a stump potted as advised, while the pot itself may be hidden or partially hidden by creeping saxifrage or *Lycopodium denticulatum*, placed round the edge and allowed to hang over the sides. If the most vigorous fronds spring from the pot and from the top of the stem, a most interesting sight is afforded by the minute seedlings that crop from the surface of the stem itself. The stems being kept in a moist state, these seedlings come up self-sown; but where even the smallest collection of ferns is grown it will be easy to shake a few spores of the most graceful kinds over the surface, and in due time the young plants will appear in groups, or crowds, or isolated specimens. It need hardly be said that the greater the variety of young plants on the stem, the more pleasing the result will be.

As to the kinds of ferns to be planted on the crest, those with running or creeping stems, like the hart's-foot fern, thrive best, creeping

all over the stem and pot, too, if permitted; but the effect in this case is scarcely so good as when some graceful kind, like the *Nephrolepis*, arches its fronds from the crest like a miniature tree fern. It is, however, best to have some with creeping stems and some of the type figured in the illustration. Of bold and strong-growing ferns that may be grown in this way, *Lomaria gibba* is probably the best. As tender and hardy ferns may be thus grown, the conservatory as well as the hothouse proper may be embellished with these exceedingly graceful and interesting objects. They need not be grown there, but they might be removed thither in summer or autumn. The plants would not suffer in a shady position, provided the stems were kept moist, which they always ought to be.

In tastefully-arranged ferneries there is no occasion to place the stump in a vase or pot of any kind, but simply on a piece of rock-work or on a bank. In cases of this kind great care should be taken to select a satisfactory position for the stumps, as, of course, they could not be moved about at will like those in pots. By a satisfactory position we mean one in which they would not only thrive, but in which they could be well attended to and conveniently seen, if possible, from more than one side. If a number were arranged in such a position, one could afford to have them at various elevations above and below the eye; if but one or two specimens only, it is

desirable to place them near or slightly above its level, so that their general effect may be seen to the best advantage, as well as the minute spray of verdure on the stems. There is no reason why they should not be used with like good effect in some shady moist nook of the out-door fernery or the rock-garden. In this case hardy kinds should, of course, be selected; and if we had nothing but the common Polypodium, which is so often seen growing on boughs, we need not be short of a subject for the top of the stem; while moss and seedling ferns and minute trailing plants may be established on the stems in the same way as in-doors.

The only difficulty that can arise is the procuring of a sufficient number of stumps. Nurserymen who import tree ferns generally lose a great many more than they desire, and therefore are sometimes well supplied with defunct stems, but these are very seldom at hand in private gardens. We believe that when this mode of cultivating ferns becomes sufficiently known, there will be a demand for these objects that will make it worth the while of some sagacious colonist to send us home a shipload or two, and they may yet be sold by every nurseryman. Doubtless many of them lie dead and useless in various parts of the world.

Field.

SARRACENIA CULTURE.

As Sarracenia are found wild in Florida and the adjacent regions of North America, it is at once obvious that they do not require, nor will they long exist in, that excessive heat, especially in winter, to which we often see them subjected. Through the months of September, October, November, December, and January, I find a temperature, by night, of from 45 deg. to 50 deg., and by day, from 50 deg. to 55 deg., to suit them best. By the middle of April, I give them 5 deg. more warmth, and through May, June, and July, I give them 65 deg. by night, with a rise of 10 deg. by day; of course in very hot weather the temperature will run higher, but they get plenty of air day and night. They are kept near the glass, and a thin shade is used in sunny weather.

The way in which I propagate them is by division of the crowns with a sharp knife. The compost I pot in is a good

has a tendency to induce a softer growth in the pitchers, which causes them to die off much sooner. During the growing season I water every day, and in winter twice a-week.

All the varieties make growth at two seasons of the year; the different forms of flava, purpurea, variolaris, and rubra, make their principal growth in spring, and then a second growth in autumn, but this latter is much inferior to that which is made in spring. The two forms of Drummondii are just the reverse in this respect; they make their principal growth in the autumn, and only a much smaller growth in spring. For many years, I used to pot all the kinds indiscriminately at the end of February, but under this treatment the two varieties of Drummondii never succeeded near so well as the other kinds. It therefore occurred to me that perhaps it would be better to defer potting these sorts until just before they commenced their autumn growth, and I found that this had a marked effect upon them, by inducing a much finer growth. I also, at this season, give them copious waterings every day, just as much as I give to the other kinds in spring. I always keep them standing on either level slate or wooden shelves kept continually damp; they will not succeed if the atmosphere around them is dry.

I would strongly advise those who may be commencing their cultivation to procure thoroughly-established plants, as there is great uncertainty in imported ones. The sorts I cultivate are these:—S. rubra, which is extremely rare; the flowers scented equal to Russian violets; S. purpurea, and a variety much finer in its veining; S. flava, three varieties, quite distinct from each other; S. variolaris; S. Drummondii rubra and Drummondii alba, the latter variety being very scarce.

Southgate.

T. BAINES.

[Our illustration, sketched at Southgate House last summer, represents one of the many superb specimens of this remarkable genus that have been grown by Mr. Baines.]

Tabernæmontana coronaria fl. pl.—A quarter of a century ago this formed a leading exhibition plant. The flowers, though smaller, are not unlike those of the *Gardenia*, pure white in colour, and are produced in bunches of two to five, and are sweet and admirable for bouquets. The plant is a very free-growing one—when it gets suitable soil and plenty of heat—but still it is not an easy matter to produce a dwarf, compact, well-furnished specimen. It is readily propagated by cuttings of the half-ripe or mature wood, though the first is preferable; and the best plan is not to trim the cuttings to a joint in the usual manner, but to cut them at two inches long, so that the growing buds may be brought as near the surface of the soil as possible. Put them in either singly in thumb pots, and, after plunging in brisk bottom heat, cover with a bell glass; or put them ten or twelve in a four-inch pot, and then cover them. A mixture of peat and loam with some sand, surrounding the cuttings with sand, will be the best medium in which to strike the cuttings. When properly rooted, which will be in about six weeks, inure them gradually to full air, and then begin to grow them on. The best compost in which to grow them will be to rich, fibrous loam from which the fine soil has been removed two pecks, flaky leaf, soil half a peck, peat the same quantity, with a quart each of crushed charcoal and sand, all thoroughly incorporated together. If the newly-struck plants are vigorous and well rooted, they may be removed at once to well-drained four-inch pots, sinking them so as to bring the branches close to the soil. Pot firmly, and if afterwards the plants can have the benefit of a bottom heat of 80 degs. to 90 degs., they will be all the better for it. This will start them into vigorous growth, and the side shoots will make rapid progress. The atmospheric temperature necessary to the best results will be a mean of 70 degs., rising to 80 degs., or even 90 degs., with sun heat on bright days, and with plenty of atmospheric moisture. When the pot is full of roots, reduce the supply of water for a week or so, and place the plants close to the glass, so as to ripen them little, then cut the shoots back to within two joints of the base, and, instead of two, you will soon have four, six, or more shoots. In this way you get what may be called a foundation for your specimen, and then the plants may be allowed to grow on for the remainder of the season. After they have been stopped and begin to grow again, the plants may be removed to an eight-inch pot, using the same compost, and continuing the treatment as to heat and moisture. If you want the young plants to bloom, that object must be effected by attending to the ripening process early in the autumn. The growth must be brought gradually to a stand, and then by free exposure to the full sun the wood must be thoroughly matured. This effected, the temperature

Sarracenia flava.

fibrous peat, broken about the size of pigeons' eggs, to which are added one-sixth of chopped sphagnum, and sufficient silver sand and crocks, broken to the size of horse-beans, to keep the soil open. On no account are the plants allowed to remain more than twelve months in the same soil, however fresh it may appear; for if left a second season, the soil will be certain to become sour, and then the roots rot as fast as they are made. When re-potting, shake them clean out. I do not approve of pans placed under the pots; and never syringe overhead, as it

of the intermediate house, 50 degs. to 60 degs., will be sufficient through the winter, and the season of blooming may be governed by the time at which you introduce the plants to a brisk growing temperature. If, however, the object is to make a handsome specimen, blooming the second season must not be thought of. Instead of that, cut your plants boldly back in February, and so soon as the young shoots make their appearance take the plants out of the pots, remove such of the old, inert soil as you can without destroying the roots, and then pot them on into pots of suitable size. The same summer treatment as to bottom heat and a brisk growing temperature may be continued, but at the same time the plants must have all the light possible, so as to induce a short, stubby growth, and hence rampant shoots may be stopped with the object of making side spurs; but this stopping must not take place later than the end of July, or the growth will not be matured. If these directions are properly attended to, the end of the second season of growth should show a plant that will furnish handsomely a twelve-inch pot; and once formed, the plants will continue to grow steadily for many years. With established plants the only care necessary is to stop rampant growth and encourage the formation of spurs; for as the plants bloom from these small shoots, we cannot have too many of them. I have omitted to mention that weak manure-water may be given when the pots are full of roots and the plants in free growth, and also at the time when the blossom buds are swelling. The plants are subject to the attacks of insects, which must be subdued in the usual manner.—A.

Tradescantia discolor.—When tastefully trained, this fine old plant has a beautiful effect either in the stove, warm conservatory, or greenhouse. A plant of it here, in the form of a pyramid about four feet in height, has been very much admired, and as its lower branches quite cover the pot, nothing could be more graceful than it in appearance, its variegated foliage being thus shown off to much advantage. For making up a collection of fine-foliated plants for exhibition, this *Tradescantia* will be found to be very useful when trained on wire or sticks, as a pyramid. Smaller plants of it will likewise be found to be suitable for table decoration; for some of the leaves acquire quite a reddish tinge with age, and the beautiful variegation exhibited by the younger foliage is seen to perfection under artificial light. The plant, if in well-drained pots, is very easily grown in any light, rich soil.—W.M. TILLERY, Welbeck.

THE FRUIT GARDEN.

STRAWBERRY CULTURE.

THREE main points to be observed in strawberry-growing consist in digging deeply, planting early, and manuring heavily. The site having been chosen, the ground should be trenched at least two feet deep; but, if the subsoil will admit of it, three feet would be better, and each spit or trench should be well covered with manure. I have used all kinds of fertilizers, and, for heavy land, I find horse manure the best; but, on light soils, cow or sheep dung is better. I layer the plants, if I can, in sixty-sized pots the first week in July, and plant them out the first week in August. By this system I have better fruit the first year than any I get afterwards; indeed, by generous treatment in the way just described, I have had Sir Charles Napier with 370 flowers on a plant the first season. The proper site for early strawberries is a south border; but for general crops open quarters are best. The finest strawberries I ever grew were planted on a piece of ground that had been under seakale for twenty-five years. But in such a case as this no dung must be applied, or you will only have foliage instead of fine fruit. When the plants are in readiness and the ground trenched, I proceed first to set out the rows three feet apart. I then plant with a trowel the balls entire, treading the ground firmly and evenly, and finishing off by giving the plants a good soaking with water.

Strawberries, planted in the manner just described, make one's heart rejoice every time one passes them. They are not the little miserable things one generally sees planted in October, which half perish during the winter. No; my plants are strong and vigorous, all of one size, and in July any individual plant is a model in its way of luxuriant growth.

The sorts which I cultivate are Keen's Seedling, Sir Charles Napier, Black Bess, British Queen, and Dr. Hogg. Take advantage of a dry day in March, and with steel forks fork the ground lightly over, leaving it in a rough state, and, just when the flowers expand, mulch with long litter, to keep the fruit clean. When colouring, I place stakes round the bed

four feet high, and on these I put nets in such a way as one can go underneath them without taking them off.

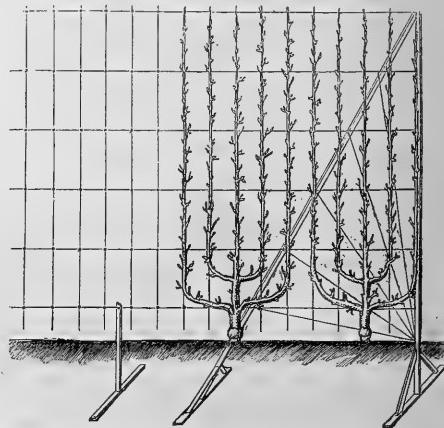

Selection, I should mention, is, in the case of strawberries, as necessary to success as in that of turnips. So particular, indeed, am I in regard to this point, that when the fruit is ripe, I mark all the best pots with small stakes, so that my stock is always improving. After fruiting is over, the plants are gradually hardened off, and the first week in May they are planted out, especially for runners. By this means I get plants a fortnight or three weeks earlier than I otherwise would, which is an advantage. In fine, open autumns, in addition to runners I have also a few dishes of fruit, the flavour of which, however, lacks that freshness which makes the strawberry such a general favourite.

Burghley.

R. GILBERT.

IMPROVED FRUIT TRELLISES.

THIS subject now appears to be receiving the attention it deserves. Properly done, these trellises are as much before the old wooden trellis in appearance as a graceful cutter-yacht is before a canal boat. And not in appearance only are they superior. They are practically everlasting; they are not expensive; they are better for the trees, and they do not waste labour in continual repairs. We fear the firms who put them up are not sufficiently alive to the importance of selecting the strongest and best form, and hence think it right to reproduce some illustrations from "The Parks and Gardens of Paris,"

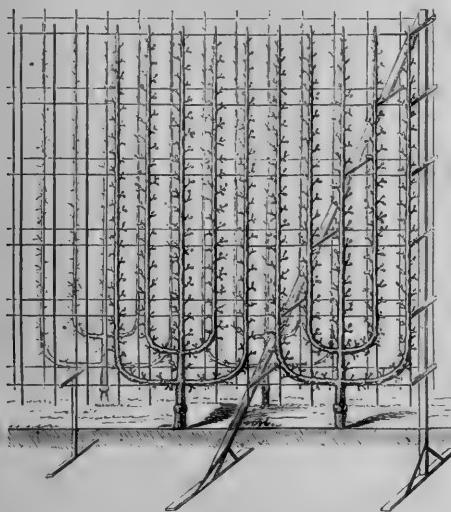

Trellis for Pear Trees: ten feet high. Uprights and stays of T-iron; horizontal lines, slender galvanized wire; vertical lines, pine-wood rods, half an inch square and painted green: to these the ascending branches are trained.

showing what the improved trellises are. So far as we have seen there is still too great a tendency to rest satisfied with the low six-foot or even five-foot trellis; this is much too low for the full development of a fruit tree. It necessitates the unwise repression and mutilation of the trees, which is too often relentlessly pursued.

The illustrations and footnotes make further description needless. There are various other modes of making good trellises, but decidedly none better than this, of which there are many hundred yards in the Government kitchen-garden at Versailles. Nothing can be neater alongside garden walks than fruit-trees trained on these trellises. There is no shaking about of rough irons or wooden beams, no falling down or loosening of the wires; the fruit is firmly attached and safe from gales, the wood is fully exposed, and the trellis, when well covered, forms an elegant dividing line in the garden. The best way to place them is at from three to six feet from the edge of the walk, and if in the space between the espalier and the walk a line of cordons could be established without difficulty, the effect and result would prove very good indeed. In some cases where large quantities of fruit are required, it

may be desirable to run them across the squares at a distance of fifteen or eighteen feet apart. The principle is quite simple, the proof of which is that the trellises at Versailles were erected by the garden workmen. The mode of employing the uprights of pine wood painted green and reaching from the top of the trellis to within six inches of the ground, is not a common one, though very desirable where the erect way of training the shoots is practised. The reader will readily perceive that this system combines the advantages of the cordon and the large tree. Of course many other forms, or any form, may be used with this system of trellising, with slight modifications to suit different kinds of trees or different forms. The double trellis shown is simply a modification of the single one, and is not only desirable where space is limited, but also for its economy, for one set of uprights supports the two sets of wires simply by using cross-bits of iron about eighteen inches long,

Double Trellis for Pear Trees: ten feet high. Uprights and stays of T-iron; horizontal lines, slender galvanized wire; vertical lines, pine-wood rods, half an inch square and painted green: to these the ascending branches are trained.

and at the desired distance apart. However, the engraving shows this at a glance.

The distance between the upright rods of pine wood is of course calculated for the training of the branches of this particular form of tree. But the same trellis will, with slight modifications, serve for various forms of trained trees.

Amateur Grape-Growing.—This has become quite a profitable pursuit in some parts of Cheshire. The first case to which I will allude is that of Mr. Cooper, a retired tradesman, who manages his vines with the assistance of a man-of-all-work. In an ordinary lean-to house, planted about seven years ago, he has Black Hamburgs trained to the roof, and Muscat Hamburgs on the back wall, with other kinds led up pillars. These vines had done, I was informed, remarkably well from the commencement. The erection of the house, heating, and border-making, were all carried out under his own supervision, and the crop this season has been magnificent, each bunch averaging about two pounds' weight, with berries large and fine. Mr. Cooper commenced grape-growing solely for the pleasure which he would derive from watching and attending to his vines with his own hands; but, being so successful, he has been induced to combine profit with pleasure, and his grapes at the present time command the highest price of any in the Manchester markets. A span-roofed viney more recently erected by him is now carrying its third crop. This is planted with Foster's Seedling, Mrs. Pince, Muscat of Alexandria, Alicant, and Lady Downes; and here I also found first class grapes, fine both in bunch and berry, and beautifully coloured, some of the bunches weighing from four to five

pounds. Mrs. Pince has not, however, for some reason or other, done so well as the other varieties. Encouraged by Mr. Cooper's success, a span-roofed viney has been put up by another amateur-grower, everything as nearly as possible having been carried out as in the first case, with the exception of the border, which consists entirely of an old, decomposed heap of couch grass that had accumulated in the corner of a field, and the crop as I saw it this season has been all that could be desired. Some of the bunches of Muscats could not weigh less than five or six pounds each. Had these growers only succeeded in producing ordinary crops, their expectations would have been realised, but I was informed that out of this house, which is only 30 feet long by 15 feet wide, forty pounds' worth of grapes had been sold each season, a statement which I can well believe, for even at our largest public exhibitions I have never seen finer fruit than that produced on this couch-made border.—E. WELSH, *Nantwich, Cheshire.*

Men like Pears.—Men often remind me of pears in the way of coming to maturity. Some are ripe at twenty, like human Jarganilles, and must be made the most of, for their day is soon over. Some come into their perfect condition late, like the autumn kinds, and they last better than the summer fruit. And some that, like the Winter-Nelis, have been hard and uninviting until all the rest have had their season, get their glow and perfume long after the frost and snow have done their worst with the orchards. Beware of rash criticisms; the rough and stringent fruit you condemn may be an autumn or a winter pear, and that which you picked up beneath the same bough in August may have been only its worm-eaten windfalls. Milton was a Saint Germain, with a graft of the roseate Early Catherine. Rich, juicy, lively, fragrant, russet-skinned old Chancer was an Easter Bourré; the buds of a new summer were swelling when he ripened.—OLIVER WENDELL HOLMES.

NOTES AND QUESTIONS ON FRUIT-GARDENING.

A Worcester Fruit Farm.—Mr. Varden has worked out the idea of a fruit farm on a vast scale, near Pershore. His estate is 23 acres. On this about 140 acres are planted with fruit trees. These consist of 60,000 apple bushes, 100,000 pears, and about 6,000 plum trees, to say nothing of hundreds of pear, apple, and other trees. The extent of the farm may be imagined when we mention that for weeks during the fruit season Mr. Varden has sent off four or five tons of fruit a day. One lot of currants sent away on one day to one customer weighed seven tons.

North Aspect of Fruit Walls.—With me the Morello and Kentish cherries are always larger and finer on a north aspect than on any other, and I have likewise had the May Duke, Bigarreau, and Elton grown with good flavour under the same circumstances. The Flavescens Léonard, and the Morello with which I often grafted up, as well as all white currants and Warrington gooseberries, I find that the Winter Nelis pear, when ripened on a north aspect, is of good flavour and keeps late. By having this variety ripened on south, west, east, and north aspects, a succession can be had in season for two months. Some kinds of plums are likewise excellent with me on north aspects, especially the Golden red greengage and Ickworth Impératrice. The latter hangs till quite shrivelled, and is then delicious; and, when gathered before the frost injures it, can be kept in the fruit-room for months.—W.M. TILLEY, *Wolverhampton.*

Will to Owners of Large Gardens.—It would be an excellent plan in certain places to cause the gardener to raise an annual batch of the very best kinds of pears, plums, apples, cherries, &c., for planting wherever it might be thought desirable, as well as for giving away to labourers, cottagers, &c. A present of a few good kinds of fruit-trees to such people might in the end serve them infinitely more than double the amount spent in other matters. For the young trees would grow into goodly specimens within a few years, and then yield annually more fruit than original cost. The people who have the additional pleasure of knowing that while the homes of poor people were made the more interesting and attractive, a very desirable addition to their material comforts would be made at the same time. All the sunny walls of labourers' cottages, &c., should be covered with fruit-trees, and even the north walls might be covered with Morello cherries, or early summer pears, like Summer Doyenne; ay, even the very roofs might be covered with valuable fruit in many instances. This, of course, applies as well to every species of fruit-tree, and the additional pleasure of knowing that while the homes of poor people were made the more interesting and attractive, a very desirable addition to their material comforts would be made at the same time. All the sunny walls of labourers' cottages, &c., should be covered with fruit-trees, and even the north walls might be covered with Morello cherries, or early summer pears, like Summer Doyenne; ay, even the very roofs might be covered with valuable fruit in many instances. This, of course, applies as well to every species of fruit-tree, and the additional pleasure of knowing that while the homes of poor people were made the more interesting and attractive, a very desirable addition to their material comforts would be made at the same time.

Profitable Fruit Culture.—Fruit culture can only give profitable results under the following conditions:—Firstly: A method of cultivation and training must be adopted that, with a given surface of land, will yield the maximum result in the shortest space of time. To this end, we must renounce all the fancy systems of cultivation adopted by those who are fond of fruit culture, and return to plain, simple, natural methods for the pleasure of overwintering them, and turn and twist trees in all kinds of fantastic shapes, thereby sacrificing profit to form. Secondly: We must only grow fruits of the finest quality in cases where they have to be sent a long distance to the places of consumption. In fact, this kind of produce, having a pretty high intrinsic value, can be sold at a sufficiently large profit, although it has to bear a heavy charge for packing and carriage before reaching the consumer. The cost of the fruit, however, must be reckoned, and no matter what the value of the produce may be—are added to the prime cost of fruit of medium quality, there will be no longer the proper proportion between the cost of production and the expense of packing and transport that will yield a sufficient profit to the grower. Thirdly: We must only cultivate in each locality those kinds of fruit which are adapted to it, and to come to perfection without any very large amount of attention, in which case the net profits will of course be large.

THE GARDEN IN THE HOUSE.

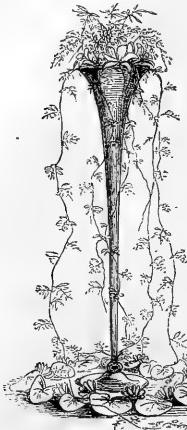

TRUMPET-SHAPED FLOWER-VASES.

THIS simple form of flower-vase has always been a favourite with me. If I were compelled to restrict myself to any one form of vase, this would be the kind which I should choose before all others.

At the same time, I should like to point out which particular variety of trumpet-shaped form I prefer. It is that in which the height is not less than three times, and not more than four times, the diameter of the foot; in which the diameter of the top does not exceed the diameter of the foot; in which the lowest part of the stem is about one-eighth of the diameter of the foot; and in which the size of the tube increases almost imperceptibly through the lower half, and more decidedly up to seven-eighths of the height, above which it should open out into a nearly flat mouth. Such vases as these are pleasing objects to the eye even without any flowers in them; and this is mainly owing to their not having any straight lines. Contrast the gracefulness of outline of the three vases dressed with flowers with the stiff, ungainly forms of the two without flowers; and then I feel sure you

Flowers and Trailing Fern, surrounded by Water Lilies. —sur- will agree with me in thinking that, as there are no straight lines in nature, so there should be no straight lines in flower-vases.

One great advantage afforded by trumpet-shaped vases is that they require so few flowers and leaves; another is, that they are so quickly and easily dressed; last not least, they show off choice flowers most effectively.

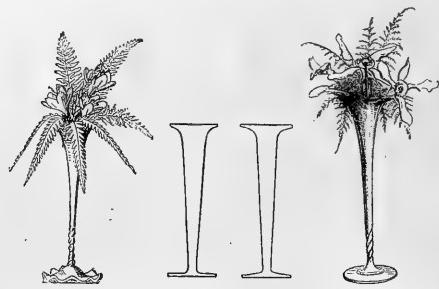

Trumpet-shaped Glass Vase, with Flowers and Trailing Fern, surrounded by Water Lilies.

All these glasses can be procured from most of the London glass works, where they are kept in stock, together with a smaller size of ruby colour about five inches high. This smaller size is of great use to me when the size of the table necessitates large dishes of flowers; for instance, in the middle of a round table large enough for eighteen people to dine at, a raised bank of moss, studded with white camellias and cerise geraniums, looks exceedingly well, the more so if a tall, trumpet-shaped vase rises from the centre; but it looks better still if the circular bank is surrounded by a ring of these little ruby vases, each containing two small pieces of Maidenhair fern and one spray of white Bourardia. The points of the large fronds, used as a fringe to this mossy bank, should lie on the table-cloth between the ruby glasses. W. T.

Orchids for the Sitting-Room.—Orchids are not as yet very generally used for the decoration of apartments—a use for which many of these beautiful plants seem pre-eminently adapted. That they are used for the decoration of the dinner-table occasionally we know, but it is a rarity to see any orchid used in drawing-rooms; and yet we have many species that will make a vigorous growth out of doors during the summer if placed in a sheltered position; and we know of instances in which some of the more common species have been well grown in Ward's close cases for many months together. Some orchids bloom after their growth is matured, and finish flowering before they again commence growing; and these are the best to employ for the sitting-room, as they can be again transferred to the orchid-house before they commence their growth, and there is comparatively no danger of their being injured. To these last belong some of the cool Odontoglossums and Oncidiuns, Cœlogyne cristata, *Lycaste Skinneri*, besides many of the glorious Cattleyas and *Lesias*. *Cœlogyne cristata* is one of the finest of all orchids for in-door decoration, and during the past very severe winter we repeatedly used a fine plant, with thirty or forty spikes, for the especial decoration of the dining-room, and occasionally for the front hall. Under gaslight this is one of the loveliest objects imaginable, the white colour of the flowers being dazzling in its purity under artificial light. The temperature of the orchid-house in which this plant was placed last winter frequently descended to 38 degs., or only 6 degs. above freezing-point, and yet this plant is uninjured. Another Indian orchid, *Aerides odoratum*, we had last winter in an ordinary lean-to, the temperature of which descended frequently to 40 degs., and probably lower. Crotons succumbed to this treatment, but two small plants of this *Aerides* are as healthy as ever, and are now growing and flowering vigorously. It would be folly to recommend Indian epiphytes, as *Phalaenopsis*, *Vandas*, &c., to be removed to the house in the winter season; but with many of the Odontoglossums, *Lycastes*, &c., this may be done with impunity if due precautions are taken in frosty weather to prevent the plants being frozen in transit. *Lycaste Skinneri* and its many beautiful varieties will last for weeks together in an ordinary sitting-room, the temperature of which does not sink below 40 degs.; and the same may be said of *Odontoglossum Alexandrae*, *Oncidium nubigenum*, and many other species of orchids from the cool summits of the Peruvian Andes. During the summer months there is little danger to be feared if the plants are set in a sheltered position in the room, and not subjected to cold, cutting draughts; but in the winter we would strongly recommend the use of close cases; while for small plants, such as *Sophronitis grandiflora*, *S. cernua*, *Cypripedium insigne*, *C. venustum*, &c., common glass-shades will suffice to protect them from cold draughts and the aridity of the atmosphere, which last is most to be feared in sharp frosty weather. The compost in the pots should be allowed to get comparatively dry before they are removed to a lower temperature, there being several degrees of difference in temperature between soil that is wet and dry. The following is a list of orchids suitable for the decoration of the sitting-room:—*Lycaste Skinneri*, *L. cruenta*, and *L. aromatica*; *Cœlogyne cristata*; *Oncidium nubigenum*, *O. Phalaenopsis*, and *O. cucullatum*; *Cattleya citrina*; *Laelia albida*, *L. autumnalis*, *L. furfuracea*, and *L. anceps*; *Barkeria spectabilis* and *B. Skinneri*; *Sophronitis grandiflora* and *S. cernua*; *Ada aurantiaca*; *Odontoglossums*, many species, *O. Alexandra* and *O. Pescatorei* being amongst the best for the purpose.

Fontenelle and his Asparagus.—He had a great liking for asparagus, and preferred it dressed with oil. One day a certain *bon vivant* Abbé came unexpectedly to dinner. The Abbé was very fond of asparagus also, but liked his dressed with butter. Fontenelle affirmed that for a friend there was no sacrifice of which he did not feel himself capable, and that half the dish of asparagus he had ordered for himself should be done with butter. When they were talking, waiting for dinner, the poor Abbé fell suddenly down in a fit of apoplexy. Upon which Fontenelle instantly springs up, scampers down to the kitchen with agility, and cries out to his cook, “The whole with oil; the whole with oil, as at first!”

Vase with Vallota and Ferns.

Bad Forms of Vases.

Vase with a few Orchid Flowers and Ferns.

In the accompanying illustrations the largest glass was three feet high. Its top was filled with clean moss, which surrounded the well-washed roots of a strong plant of *Lygodium japonicum*, the fronds of which hung down and trailed upon the table-cloth. Into the moss were placed three splendid flowers of the dark-red *Hibiscus rosa-sinensis* and a few fronds of *Gleichenia dichotoma*. At the base was a ring of the flowers and leaves of our common white water-lily (*Nymphaea alba*). The glass containing the blooms of *Vallota purpurea* was ten inches high. At the back were two fronds of *Lastrea decurrens*; on one side, a frond of *Davallia elegans*; and in front, a four-parted frond of *Gleichenia flabellata*. The glass with the three blooms of an *Odontoglossum* was nine inches high, and the fern-fronds in it were those of *Hypolepis distans*. This vase was made of ruby glass, a material which shows off some kinds of flowers to great advantage.

THE KITCHEN-GARDEN.

STORING OF ROOTS.

It has long been customary to take up Jerusalem Artichokes, Carrots, Beet, Parsnips, Salsify, Scorzonera, &c., and to winter them above ground. If in small quantities, they are stored in sand in a cellar or dark shed. If in large bulk, they are clumped, or placed in ridges out of doors, and protected against severe weather. Onions and Shallots are generally placed on shelves or benches in lofts or store-rooms.

Respecting the Jerusalem Artichoke: I have always found it best to leave the roots in the ground, where no frost ever injures them. I always cut off the stalks in December, leaving a foot or more in height standing, in order to indicate where the rows are, and mulch with litter or leaves; fern or green bough prunings are laid over the litter, &c., to keep the wind from driving it about. In March I trench out all the Artichokes, turning in the mulching, rubbish, toys, or stalks, and replant with whole moderate-sized tubers, four feet apart from row to row, and two feet plant from plant. After replanting, such as were fit for use were stored in a cold, shady place, and the small and refuse were kept for poultry and pheasants, for which they make good and wonderfully well-appreciated food.

Carrots should be allowed to get quite ripe, and to have entirely finished their growth, previously to taking them up, and particular care must be taken in the storage of them, as they are very liable to heat if stored together in large quantities. Where carrots are grown merely as a garden crop, and only in sufficient quantities for the supply of the establishment—to maintain firmness, crispness, flavour, and colour, they are best stored out of doors in a cold, shady aspect in thin ridges. Cover the latter with a little loose dry straw, then with some wood faggots, and let the whole be thatched over. Thus managed they will till the next summer free from growth and excellent in quality; while, if placed in sand and in a cellar, by New Year's-day, or sooner, they will be found to have begun to grow, after which they are tough and tasteless, with a heart like a stick. Young carrots after the French fashion are, however, what I like, and it is quite possible to have them all the winter, and, indeed, the whole year round. Let them be sown in July and August, and mulch them lightly, previous to frost setting in severely in December, with straw, pea haulm, fern, evergreen boughs, &c.; you will thus have capital young carrots every day during winter; sow again in September and October on light hot beds, and you will have them for early spring. Indeed, as I have stated, young carrots may be had every day in the year by means of successional sowings. Where old carrots are stored in large quantities, pitch some hurdles strongly staked four feet apart, place some faggot-wood in the bottom, then fill up to the top of the hurdles with carrots, finishing them off in the form of a roof at top. Place a faggot upright every eight or ten feet apart, in the middle of the ridge; barricade the sides and top with faggots, thatching the roof only. The circulation of air thus secured prevents fermentation, and keeps all sweet and sound. Of course, if severe weather sets in, the outside faggots should be covered with straw, fern, heath, or furze, in sufficient quantity to keep out frost; for carrots out of the ground will not stand without injury.

Beet will withstand a good deal of frost; but if allowed to get much frozen, it loses both flavour and colour. I have always, therefore, made it a rule to take it up in December when quite ripe, and to lay it in thickly in some sheltered corner, covered with earth an inch or two up the leaves. Thus stored, it maintains its natural properties unimpaired.

Parsnips are always mild in flavour, and otherwise excellent, if allowed to remain where they grow, and taken up as required for use; but when taken up and exposed to the atmosphere, if only for a very few days, their good properties are gone—yes, gone. They get yellow, and so strong in taste as to be generally disliked. Besides, if taken up and stored in sand, except in a very cold aspect, parsnips soon begin to grow, and then their taste is as bad as that of a rank green potato.

Scorzonera and Salsify, also, always retain their natural flavour and qualities if left in the ground where they grow, and mulched sufficiently to ward off severe frost, previously to winter setting in.

Turnips, when young, crisp, and sweet, are delicious. Late-sown free-growing bulbs suffer more from frost than others. I therefore always pull and use them as long as I can, looking out for frost and then pulling a quantity before being frozen. I then lay them in thickly in a sheltered spot, well covering both tops and roots.

Amongst culinary vegetables few are more useful than the onion, which is in daily request both by poor and rich; and to be able to have it in perfection at all seasons is a desideratum. As regards storing onions, that is done in various ways. An important point is allow-

ing them to get really ripe before storing them; and for harvesting them a dry day should be chosen. Pull, and tie them in bunches of eight, ten, or more, together, according to size; then take them away, and hang them up at once on the rafters or beams of open sheds, or in well-ventilated lofts. In such situations they will dry gradually and thoroughly. As the wet days of winter come on, a portion might be taken down and roped, if approved of—that is, as all know, strong on straw or other bands, and then hung up; or they may be topped and cleaned, and placed on loft-shelves and benches. But, for many years I never took further trouble with my crops of onions than to pull, and tie them in bunches of convenient sizes, and hang them up as just described, taking portions of them down now and then as required for use, and I have always found them to keep well until the following summer's early onions were ready for culinary purposes. I do not approve of onions being pulled, topped, and disrooted, and then allowed to lie on the ground exposed day and night, turned about and bruised, and then taken to some loft-floor, shelves, or benches. Thus treated, many are apt to show blotches and to decay early, and they have also a tendency to run or start into growth, which at once deteriorates their quality. Besides, onions exposed, after having been pulled, to sunshine, rain, and wind, get so hot and strong, that having anything to do with them is most unpleasant.

JAMES BARNES.

WORKING IN THE WET.

This is as improvident as it is cruel. Let me not be misunderstood. A summer shower hurts no healthy man, and there are occasions—such as the planting-out season in May or June—when to cease working because of a passing shower might involve the loss of weeks, perhaps of a season. It is not of such exceptional working in the wet that I now write. In summer little harm comes of getting slightly wet if one but continues to work or walk. Colds are caught by standing or sitting still in wet clothes. But what should be avoided is working in continuous rain at any season, or getting wet at all in cold weather. I have known gardens where such rules as the following prevailed:—When too wet to hoe, digging was ordered, and when the ground became so sodden as to render this almost impossible, the earth holding on to the spade like birdlime, the spade was exchanged for the scythe. And it was never considered too wet to mow. I have seen men come off lawns with their shoes full of water and their clothes sticking to their backs. Such exhibitions are, however, now rarer than they once were—thanks to mowing-machines, greater independence among workmen, and more humane management among masters. Still, I believe, working in the wet is by no means extinct in many gardens. I have said that such work is cruel and improvident. It cannot be needful to prove the first. Rain penetrates into the system, and undermines health, and health is the working man's capital.

Working in the wet is, moreover, the dearest of all work, and the worst. If performed on the ground it is worse than useless. Earth moved in a wet state runs together, adheres somewhat like molten metal, and becomes, in a measure, equally stubborn and barren. Trampling on the earth in a wet state is likewise highly injurious. It breaks down the texture of the soil, hinders the free percolation of water, and drives or shuts out the air. Even planting in the wet, so much advocated by some, is not to be commended. The earth fits in more closely around the roots, and the roots take a kindlier, speedier grip of it when applied to them in a comparatively dry state. True, water is a capital consolidator of the soil. But it does its work best thus:—First of all lay the earth in position in a dryish state, and then let the rain or watering-pot dash the mellow soil into every nook and cranny. But let the rain convert it into a sticky mortar first, and mark the difference—you will need no other evidence against the impolicy of working in the wet.

Then, as regards other work, such as that on walls or on grass, working in the wet is the dearest of all work. The discomfort is a hindrance to the worker. There is no end of stoppages, countless fragments of time lost in cloud-gazing, weather prognostications, peevish complainings, &c. In a word, the physical stamina is washed out, and the result is little or no work. Fortunately, working in the wet in well-ordered gardens is as unnecessary as it is wasteful. With ordinary forethought it may easily be avoided. Inside work abounds in most gardens. Most of it, too, is helpful to the

work outside. So much, indeed, is this the case that, in a large establishment with much glass, I have always difficulty in getting the outside men to assist under glass in wet weather. The answer is generally, "Very well, master; but we have stakes, labels, pegs, &c., that will soon be needed for so-and-so;" and the men are generally right. Each is held responsible to provide in foul weather everything that is needed in his department when it is fine, if enough of wet weather be found for the purpose, and, singular though it may seem to many, it is seldom that this is the case. The experience of many years thus comes to the aid of humane management to give emphatic testimony to the fact that there is no necessity for working in the wet.

D. T. F.

Raising Potatoes from Seed.—The following observations by Mr. George Such, in the *American Gardeners' Monthly*, on raising potatoes from seed will probably prove interesting to many who think the process is attended with any difficulty. Mr. Such's garden, which I had the pleasure of visiting last autumn, is on the sandy soil of New Jersey, near South Amboy, enjoying, of course, a good deal more summer heat than we do; but there can be no doubt that by beginning early, quite as good a result could be obtained in England. W. R. :—Mr. Patterson, to whom Englishmen are indebted as the originator of many good potatoes, gives it as his opinion that the production of new varieties from seed is attended with so much labour and expense that it should be undertaken by the British Government, and not by individuals; and the supposed difficulties could hardly be more absurdly exaggerated than they are in a late number of a well-known English horticultural journal. Now, the simple fact is that it is an easy matter to get a tolerably good crop of potatoes within five or six months from the time the small seeds are sown. I have now in my cellar more than two hundred varieties of potatoes, very many of full size, all of which were produced from seed taken from the potato ball a year ago. It was said to be Early Rose, fertilized with white Peach-blossom and other varieties. The seed was sown about the end of March, just as tomato seed is sown. It germinated readily, and the little seedlings were soon pricked out into pans. In fact, the plants were treated precisely the same as tomato plants, except that they were moved to a cooler position than tomatoes required. Towards the end of May the potato plants were set out in rows, just as potatoes are usually planted, plenty of room being left between the rows. Only this difference was made—very important, however, I think—the potato plants were not set on the level of the ground, but four or five inches below it, like celery in trenches. They soon struck root vigorously into the good soil that had been prepared for them, and grew rapidly, the soil being gradually filled in as fast as the strength of the stalk seemed to admit of it. By the end of June the trench was all filled in to the level, and after that only one slight earthing-up was given. In August the potato vines were as large and flourishing as if grown from sets. In this month, too, the first of the potatoes were dug, and from that time others matured, some varieties being early and some late, until the last of October."

THE PROPAGATOR.

Grafting Azaleas.—It is by means of grafting that varieties of Azalæas, both new and old, are increased. As regards stocks, two varieties have been in general request: the one, the old A. rosea elegans; the other, the newer, A. Sir Charles Napier. There is some diversity of opinion as to the suitability of these two stocks; some growers resolutely hold to the one—some to the other. Certain it is that, in point of habit, Sir Charles Napier seems admirably adapted for the purpose, having a stiff, sturdy habit, and wiry wood. In order to prepare stocks for grafting, cuttings should be taken at the proper season, potted off singly into small sixty-sized pots, and grown on till they are from ten to twelve inches in height, and as thick in the stem as the small end of an ordinary tobacco-pipe. New Azaleas are, as a rule, received from the Continent in September and October, and it is then grafting is generally performed, or as soon as there is sufficient young wood on the newly-obtained plants to furnish scions. The stem of the stock is divided by an horizontal cut from four to six inches from the bottom, as the case may be, and, by inserting the knife at the top, a cut is made in a downward direction. The scion is prepared by having both of its sides sliced off, so as to fit into the vertical cut made in the top of the stock. It is inserted, and tied closely together by means of a piece of bast, then placed in a moist, close heat, and thus circumstanced very few indeed fail to adhere, i.e., if the barks of both stock and scion are nicely fitted together. In this way any variety can be rapidly increased, if sufficient stocks can be had on which to operate.—R. D.

Tree Carnations.—Plants of these to furnish "button-holes" or flowers for other decorative purposes, should be kept cool and clean until Christmas, when they should be placed in gentle heat in order to induce them to make shoots for cuttings, which will be found to strike root readily on a slight bottom heat. After having struck, they should be potted off immediately into thumb-pots, giving them two shifts into larger sizes before the first week in June, when they should be put into thirty-two sized pots for flowering. Pot them firmly in loam mixed with rotten cow-dung, and afterwards place them in beds out of doors.—C.

Lapageria rosea.—This fine climber is planted out in the Lea Bridge Nurseries, and bears hundreds of seed-pods about two inches long, and nearly an inch through. Each pod furnishes from fifty to a hundred good seeds. It is curious that these pods were all produced by the late autumnal flowers of the year. It is so every year. The summer flowers that one would expect to be the most fertile do not produce seed-pods; the October and November flowers do. From the seed an abundance of vigorous young plants may be raised; but if the seed be not sown soon after arriving at perfection—as soon as fit to gather, in fact—it will prove of very uncertain germination. If kept over till the succeeding spring, it may not grow at all. This, with like cases, points to the fact that we often lose a great deal by keeping seeds, it may be six or nine months, for the arrival of spring. Sometimes the little plants of *Lapageria* bloom at six inches high, and when eighteen months old.

NOTES AND QUESTIONS ON PROPAGATION.

Case for sending Growing Plants to Distant Countries.—At a meeting of the Edinburgh Botanical Society Mr. McNamee placed on the table a small case of plants, received from Dr. Mitchell, of the Botanic Garden, Melbourne. This case contained seven species of plants, all established in pots previous to being sent away. It is rarely that we see comparatively soft-wooded plants brought home in such good condition, and in so simple a manner. The case was 105 days on the voyage, and the plants were only once watered, but had occasionally sprouted, and, after a short time, were kept on deck during the day, and so placed that no salt water could reach them. It is thus constructed, a rough unplaned old box, 13 inches long, 11 inches broad, and 6 inches deep, has two upright pieces of wood, 16 inches long and 2 inches broad, nailed, one in the centre of each end of the box, and a piece in the same breadth and thickness nailed across the top, giving it a ridge appearance. Over this a piece of thick unbleached cotton is stretched, and firmly tacked down. The ends are likewise covered with cotton, and the whole is bound with twine. The cost of this case, costing not more than £s. or £s. 6d. altogether it will be found of great benefit to amateurs wishing to take out or bring home a few choice plants. The pots containing the plants fill the box, and are kept from moving by having a little damp moss introduced between them, and also over the surface of the soil. In the ordinary Wardian cases, which are usually filled with soil, the plants are turned out of pots and placed in the earth, often only a few days before being sent away. In this instance no time is lost in turning out the plants, which would require a period of three or four weeks, whereas, in the case of well-established plants sent in pots, a few hours' notice previous to removal is all that is required. The light which the cotton allows to penetrate, and the air which reaches the plants through its fine meshes, seems to be more favourable for the preservation of delicate or soft-wooded plants, both as regards colour and substance, than the ordinary heavy air-tight glazed Wardian cases, which not unfrequently prove fatal to tender plants, by causing them to become pale and much drawn up.

Packing Seeds for Long Sea Voyages.—The seeds of all the haws or cattleyas may be exported to any country with the greatest certainty, by packing them in casks with a little sawdust mixed with the seeds. It is customary with nurserymen and others who raise thorns from seed, to bury the haws for some time, so that the pulp may rot off, and also for the purpose of saving time and ground. The rotting that the haws undergo in their casks or boxes serve the same purpose, and the seeds will be ready to sow when they arrive. Seeds of plants which may be expected to grow very differently in different climates, or which are liable to undergo a change of climate, or which require special treatment. Some seeds—like those of Berberis, for instance—should be sent dry, the seeds washed from the pulp, dried, and packed in the usual way in strong, dry papers as seedsmen do, and they will travel safely if kept in a dry place. Cranberries should also be cleaned out and sent as dry seed. Blackberries should be washed out as strawberries are, and the same treatment given. In the Arbutus, Ostrya, and like plants, the stones may be sent packed in single boxes, or little cases or jars. These should, however, be mixed with dry and finely-powdered charcoal. Laurel is a difficult seed to export. The most practised hands have tried and failed with it. This also applies to the Portugal laurel. Perhaps the best way to send these would be to sow the seeds on the surface of the soil in a Wardian case, where they could vegetate; or, better still, to raise them an inch or two, and then plant them in little boxes, so that we have a supply of fresh leaves for the purpose. Azaleas. The wild roses may be sent with safety, and to be extracted from the hips and dried. Siberian crab seed will go as well as apple seed, and in the same way—the pits sent out in dry packets, just as nurserymen send us our vegetable seed. But all those seeds that are to be kept dry should be kept away from the moist, pulpy ones—quite isolated, in fact, or farewell the dry seed. Some people, in taking out seeds, put a bag of pulpy moist tree or shrub seeds in with them, so that the dampness and pulpsiness, peas, and pelargoniums come out so much mouldy. Ivy will come equally well if dried, or sent out in the pulp like the hawthorn fruit. There is no difficulty in sending the seeds of conifers; they are "dry" seeds, and merely require to be kept free from damp. Chestnuts are very difficult to send. (No doubt the best way is to sow them in the Wardian case, or raise them beforehand, and plant densely in it; but this is sending plants, not seeds. Oaks are rather difficult, and should be raised and sent as described above in the case of the cork oak.)

THE HOUSEHOLD.

SALADS.

In the materials for a good salad are sweetness, crispness, and tenderness. Negatively, a salad must neither taste strong, feel tough, nor eat hard. To make a good salad, then, the first step is, begin by packing all those positive excellencies into our material. How is this to be done? Certainly not by growing lettuces and endive on any out-of-the-way, poor bit of ground or border, as is too frequently done. No, nor by permitting the plants to crowd and smother each other in the seed-beds until they are ruined for life. Nor yet by rude, rough removals, or ruder plantings and neglect afterwards. On the contrary, to grow perfect salading, the plants should receive no check on their journey from the seed-leaf to the salad-bowl. Quick growth clothes both lettuce and endive with all the qualities indicated. To promote and sustain this quickness of growth the soil must be deep, rich, light, moist, and, to a certain extent, warm. In other words, to make first-rate salading,^{our} lettuce and endive must receive the highest cultivation; and truly there are few things more worthy of it. Hardly anything that our gardens produce is more enjoyable or wholesome than a good salad. It is therefore high time that the contentious axiom, "What is worth doing at all, is worth doing well," was applied to its cultivation. High culture applied to lettuce speedily tells, and assuredly pays. Neither have we long to wait for results. The plants rush along well-laid lines of growth, and plump up into rich, juicy, massive sweetness, as impatient for a "header" into the salad-bowl. Much depends upon cutting them at the ripe moment. There is a tide in lettuce as in the affairs of man, which, taken at the flood, leads on to the good fortune of a perfect salad. That tide is the moment when growth is compacted into solidity—when every tender leaf and stem is brittle as glass, charged with rare virtue, and filled to overflowing with good flavour and rich juices. Having secured it at the right moment, we must have a care that it is not ruined on its passage, full of risk and danger, from the garden to the salad-bowl. Lettuces should be handled with clean hands, no leaf should be roughly crushed nor soiled with dirt; every bruise lets out juice and lowers the quality; and dirt on lettuces is ruin. True, it can be washed off after a fashion; but water washes out the flavour. Pitch them into water for an hour! Ah! horror of horrors! Almost as well pass them through the fire. The water sinks in through the lettuce, taking out its rich juices, and occupying their vacant place.

The superiority of Continental salads is owing simply to their being grown in a perfectly clean manner, and gathered exactly at the right moment. To hope to gather good salads in winter in the open air in our climate is madness; those who depend in winter on unprotected material exposed to lacerating hail, and chilled by heavy cold rains, cannot have good salad material for months at a time.

D. T. FISH.

NOTES AND QUESTIONS ON THE HOUSEHOLD.

Preserving the Tomato.—In America the "canned" tomatoes are quite as good in winter as the fresh ripe fruit is in summer. The following simple American method of preserving them is worth noting. It is from the *American Agriculturist*:—"Having sometimes failed with glass jars, we now use tin cans, which are made of thin sheet metal, and are about one and a half inches, and scarcely made." A hole, say 13 inch in diameter, is left in one end. The tomatoes, in large quantities at a time, are cooked well, as for the table, but without salt. They are poured into the cans hot, and a bit of tin well soldered on. We put up fifteen to forty cans at a time, and call in a tinsman to do the soldering, as we have a large number of cans ready at a time. Thus closely sealed they will keep perfectly a month, a year, or five years. Scald the emptied cans and set them to dry, and they can be used several times with a little help from the sun to scald the holes again.

Frothy Value of Fruits.—Fruits are used as a staple food in many warm countries; but in most parts of Europe they are regarded chiefly in the light of luxury, i.e., Deprived of their stones or seeds, they contain often not more than 5 per cent. of solid matter. They are very poor in albuminoids; but they are usually rich in sugar, and many of them contain much acid. There is a remarkable variety in the relative amounts of pectose, sugar, and acid in edible fruits. Berries contain, as a rule, more acid than pectose, and some of them contain from 13 to 20 per cent. of sugar, the cherry only 14 per cent. In the peach there is about 9 per cent. of soluble pectin and gum, whilst the gooseberry includes only 2 per cent. of these bodies. In the common fruits the percentage of free acid varies from a mere trace to about 3 per cent. The pear is almost always free from acid, whilst the currant often contains three times as much acid as sugar. The grape is probably the best fruit adapted for the sick. As to weight and force produced, 1 lb. of grapes, 6½ lbs. of cherries, 10 lbs. of currants, and 12 lbs. of strawberries, are equal to one pound of starch! The dietetic value of the fruits is chiefly due to their fine flavour and their abundance of saline matter.—DR. CAMERON, in *Irish Farmers' Gazette*.

Hip Jam.—Collect the hips from the rose-bushes when ripe, boil them in water until they become soft enough to be easily crushed, and press them through a very fine sieve. Take an equal weight of sugar to that of the fruit, boil the hips, when pulped through the sieve, thoroughly with the sugar, and pour the jam into a large stoneware jar, and able to ferment a good deal, and therefore remains sweet. When taking up jam for use, mix and stir it up well with a little white wine, and add sugar to taste if required. This jam is excellent, either for eating alone as a sweetmeat or for making sauce.

A Party from the Salad-Bowl.—In 1820 a party of dandies, Gaul having fled the guillotine at the end of the last century, and finding himself without cash in this country, contrived to pick up not only a living but a competency by taking to salad-making as a profession. This is how it came to pass—we abridge from Brillat-Savarin:—A French *cuvier*, named D'Albignac, was dining at one of the most fashionable taverns in London, when he was addressed by a party of dandies who occupied the table next to him with a request to mix in with them a couple of very polite compliments upon the prosperity of the French nation in the time of Louis Philippe. D'Albignac, with some difficulty conciliated, being provided with the necessary ingredients, was very successful. In the course of the proceedings he entered into conversation with these people, and in answer to their questions he frankly avowed his position; consequently they felt justified in asking his acceptance of a five-pound note, which he accepted without much pressing. The dandies asked for his address, and a few days afterwards received a request to go and mix a salad at one of the biggest parties in the capital. D'Albignac, however, had not been slow in availing himself of it. Providing himself with some choice condiments, he went, and was eminently successful. He was paid in proportion to his success. In a short time his reputation began to spread, and all the people of fashion in the capital of the three kingdoms were dying to have a salad mixed by the French gentleman—the fashionable salad-maker, as he was called. He soon set up a *carrick* (i.e. currie) to go about in, and a footman to carry a tray containing a small dish of salad with such a variety of various flavours, oil with or without the taste of olive, &c. Later he supplied similar cases ready fitted with ingredients, and sold them in hundreds. In the end he amassed some \$0,000 francs, with which, the guillotine having been superseded in his native country, he retired thereto, where he lived happy ever afterwards.

THE AMATEUR'S REMEMBRANCER.*

In-door Department.—The most enthusiastic lover of hardy plants and the free air will now be glad to avail himself of the delicious shelter and genial clime which glass enables us to create in our gloomy winter climate. Although the frost may bite, and wind pierce without, the winter-flowering greenhouse Heaths, the gay and pretty Persian Cyclamens and fresh-opening Chinese Primroses are displaying their tender charms as willingly as if it were the sun on some balmy mountain meadow that had induced them to blossom, and not the gardener's art. In greenhouses or small conservatories sufficient fire-heat should be applied to keep out frost or dispel damp, and air should only be given in the middle of the day when the weather is fine. On front shelves, the pretty early flowering plants just named, and other things of that kind will serve to maintain a certain amount of gaiety, which will soon now be greatly increased by the introduction of such plants as Diclyttras, Dentzias, Kalmias, Azaleas, Roses, Hyacinths, and other Dutch bulbs, which will be coming forward in forcing pits. Lilies of the Valley, Mignonette, and things of that sort, wanted for succession, should also now be placed in gentle heat, as should likewise the sweet Indian Daphne, Persian Lilacs, and anything of that sort which may be brought easily into flower by the application of a little artificial warmth. Prune and dress creepers, tio tio Pelargoniums intended as specimens for particular purposes, and shift forward Cinerarias into the pots in which they are to flower. Cover pits and frames at night when frosty, and remove dead leaves or anything likely to engender mould.

Fruit and Forcing Houses.—The pine-apple grower must now keep plants swelling-off fruit as near the glass as possible, and the atmosphere a little drier than it has been, in order to brighten the colour and increase the flavour. Succession plants should be kept growing without check, and should have a little air given them on all favourable opportunities. For cucumbers a temperature of not less than sixty-five degrees should be maintained at night, and about seventy during the day-time. Where early potatoes are a desideratum a few Ashleaves may be put in a gentle hot-bed to start preparatory to being planted hereafter in pits or frames. Vines may now be pruned and cleaned ready for forcing where grapes are wanted early, and, if not already done, manch the borders in which they grow with rough litter.

Flower-Garden.—Where the small-flowered Chrysanthemums have been bedded out they will soon require to be cleared away and the beds filled with bulbs or spring flowers, or thrown up rough for spring and early summer planting. Although the great majority of flower-gardens are now bare of plants or interest of any kind, that is the cultivator's own fault, for many of the evergreen alpine plants of the Sedum, Saxifrage and Sempervivum families look as well now, where properly grown and arranged, as at any other season. In fact, the mossy Saxifrages now present a fresher verdure than at any time during the whole year. Roses may now be planted as well as stocks

* Complete general calendars, written by some of the most able gardeners in the country, are published in "THE GARDEN" in the first issue in each month.

for budding on next season. Some of the more tender of the tea kinds might be lifted and laid in a dry, warm, sheltered situation, where they can receive some protection from frost. Sweep up fallen leaves, and by neatness and order in some measure make amends for the want of floral beauty.

Fruit and Kitchen Garden.—Draining, trenching, and deep digging may now be advantageously carried on in both these departments, wherever such operations are necessary. Now, when fruit-trees have shed their leaves most kinds may be pruned and nailed, and where new plantations have to be made no time should be lost in making them. When planted a good mulching of rotten dung placed over the roots will be of advantage, and stakes should be placed to standards to secure them against wind-waving. Stems of old trees may be cleared of moss by means of a good dredging of quicklime put on when the bark is moist; but the most effectual remedy is thorough drainage. This is also a good time for root-pruning such sorts as are growing too vigorously, and, on that account, forming wood instead of fruit-buds. In the kitchen-garden no satisfactory returns need be expected without deep cultivation and liberal applications of manure. Therefore, nothing capable of being converted into plant food should be lost. If not already done, fork up the surface of asparagus beds, and apply to them a good coating of manure, or sea-weed, where that can be obtained.—J. M.

SOILS, MANURES, &c.

PEAT.

To procure good peat is, in most places, an exceedingly difficult matter. I have myself traversed square miles of heath-clad mountain land, and could not find a barrow-load of peat worth taking home; and the same may be said of other soils. The kind of soil that is wanted for storing, whether it be peat or loam, is that which is so rich in vegetable matter that when the earthy particles are shaken out a tuft of it will be almost like a sponge. This, laid up a few months for the active vegetable matter to decay, constitutes the pabulum upon which the very finest plants are grown. With those who have the chance of selecting their own soils, the proper course to pursue is to go to the different places where they are to be found, and examine them till the desired quality is met with, then send carts and harvest the best. Recollect, soils do not deteriorate by keeping; peat, if kept dry, will remain good a number of years. Peat, to be of the best quality, should not be more than two inches thick, firm in texture and fibry, the upper surface covered with dwarf heath, the under resting on sand. This will generally be found in upland positions; but in dry seasons excellent peat for storing may be procured from lowland situations. Peat when brought home should be carefully looked over, divesting the upper surface of all rough herbage, and the lower of sand; then place it in ridges, two turves together in the shape of the letter A, so that the air can act well upon it; and, if early in the season, there let it remain till the rains of autumn make it necessary to stack it, if it is not wanted for use before the following summer; and it is better not to use it before that time. Or build some turf pits with it, which may be turned to good account, if for no other purpose than protecting lettuce or cauliflower plants. Thus arranged, it would be well exposed to the air that it will be much improved. Should it not be required in this way, it is best to stack it in ridges four feet high, three feet wide, and tapering to a single turf at the top. In forming the stack, place the turfs somewhat apart, so as to admit of air circulating freely among them; and if the peat is stacked fresh from the common it is best to insect an air drain in the centre. Sometimes, old pea stakes or pieces of wood are placed between the layers; it matters little, indeed, how it is done, if air can find its way freely through the mass. When peat is used fresh from the common—which should never take place in a well-regulated establishment—it will be found an excellent plan to char the outer surface. One of the best supplies of peat I ever had was from a common from which all vegetation had recently been burnt. In charring peat the turves should be cut into pieces three inches wide, as then the parts will be equally heated, which is not the case if the turf is placed on the stove whole. The charring may be done in various ways, according to the conveniences at hand; and, if carefully performed, it will answer as well as the thorough aeration which results from proper storing, while by it all insect-pests, and roots, and seeds of weeds, will be destroyed.

A.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY (DECEMBER 6TH).—This, though not distinguished by any specially important feature, was an interesting meeting. Among the more instructive objects shown was a pretty batch of Cyclamens, in brilliant bloom, which had only been *sown on the 28th day of January of the present year*. When these charming plants can be grown to a blooming size almost as quickly as an annual, no greenhouse should be uncheered by their lovely flowers, which start up so profusely in winter and spring. Some beautiful blooms of Ipomoea caerulea were shown under a glass. Some cones of *Picea nobilis*, gathered from a specimen fifty-eight feet high at Sir John Sebright's, in Hertfordshire, were remarkable for size and evidence of perfect health. A rare *Yucca (longifolia)* was exhibited from Mr. Wilson Saunders' garden. A good many Chrysanthemums were shown, some among the best we remember seeing being staged by Mr. Shrimpton, gardener to Mrs. Doxat, Putney Heath. Berry-bearing plants were not by any means good, Mr. Standish being first. His group consisted of Pernettyas, Aruncus, Skimmias, and Cotoneasters. Some graceful dwarf Conifers were shown, such as the Retinospas, including the elegant *R. lycopodioides* and *Taxus coriacea*. From Mr. Pragnell, of the Castle Gardens, Sherborne, came a well-varied and excellent collection of vegetables. A new winter radish was shown from the Society's Gardens at Chiswick, which had been raised from seed brought from California by Mr. Robinson. It was shown in poor condition, but, nevertheless, received a first-class certificate. Further trials, will, however, be necessary to prove its value in this country, and also to test its distinction. Mr. George Johnston sent two superb Cayenne Pine-apples, to which a special certificate was awarded. A new Grape, named *Waltham Cross*, large in berry and large in bunch, was shown by Mr. William Parry, in excellent condition. Messrs. Lane, of Great Berkhamsted, again sent a collection of their noble Grapes, to which a special certificate was given. A very graceful species of *Asparagus*, viz., *A. decumbens* was shown by Mr. Standish; and a rich deep crimson *Cyclamen*, named Queen of Crimsons, came from Mr. Goddard, gardener to Mr. Little, of Twickenham. This last received a first-class certificate. From Messrs. Veitch came several plants of a yellow-fruited Capsicum, called *Yellow Gem*. These were admirable, a grown in single stems of a foot or so high, and each was furnished with from eighteen to twenty-four fruit. A fine collection of hybrid Solanums, covered with berries, from Mr. Williams, of Holloway, bid a special certificate. Mr. Williams also exhibited a variety of *Lycopersicum Skinneri*, with two flowers borne so closely together that they almost resembled double flowers.

Royal Botanic Society.—The spring shows of this society for next year, announced to take place on March 13th, April 10th, and May 8th; the summer shows on May 22nd, 23rd, June 19th, 20th, and July 10th, 11th; all two-day exhibitions.

International Fruit and Flower Show at Glasgow.—A great fruit show is to take place here in the second week of September, 1872. At a meeting of gentlemen nominated to organise and manage the exhibition, it was decided that the entrance fee should be £1000, the amount of £1000 shillings to be collected, and that a prize schedule should be issued forthwith, in which price be about that amount should be offered. A committee was also appointed to fix the most suitable place for holding a show of the character decided upon.

Royal Horticultural Society.—The days on which the meetings and shows for next year are as follows. Viz.:—January 17th; February 11th, 18th, 25th; March 6th, 13th, 20th; April 3rd, 17th, May 1st, 8th, 15th, 22nd, 29th; June 5th, 12th, 19th, 26th; July 3rd, 10th, 17th, 24th; September 1st, 8th, 15th, 22nd; October 2nd; November 7th, 14th, December 4th. It is to be seen that there is a two days' show in May, and three days' show in June, the latter being the special fete of the season. At and after these, some five gold medals and as many silver ones are to be awarded, this new plants. The society's provincial show, schedules for which will be issued for early in the year, is to take place at Birmingham, in, we believe, the beau-sous grounds at Aston, belonging to Mr. Quilter, on whose hearty co-operative spirit, all concerned are fully resolved. We trust, we feel sure, all concerned will fully reward him.

Irish Agricultural Society of Ireland.—The condition of this society, according to the last annual report, is both encouraging and satisfactory; the council being enabled, after discharging all liabilities, to invest a further sum of £10,000 in Government stock, leaving a balance in the bank to current account sum of £68,55.6d. In revising the schedule of prizes for 1872, the council has made considerable additions both to the money and value of the premiums, also to the descriptions of what an exhibition of fruit, provision being made for a great public fruit-show, to be held in October, which it is believed will prove both publicly interesting and of much practical value. This society owes much of its prosperity to its active, able, and most courteous secretary Mr. Ambrose Baile.

Manchester Botanical and Horticultural Society.—It has been indicated desirable to hold monthly meetings, and to have occasional meetings in connection with the Botanical Society held at South Kensington, a plan which we hope to please to see carried out in other great centres of horticulture. The meetings in question are to be held in a suitable room in Manchester, and the sittings exhibited are to be submitted to a competent committee. First and subsequent class certificates and commendations are to be awarded, at the discretion of the majority of the members present, to the novelties exhibited, according to the merit. As the members of which society are scattered throughout the country, we trust that they will aid the society's efforts in this new direction with their hearty cooperation. It is proposed next year to hold these meetings in February, March, and April, then come the summer shows at the Botanics Gardens, and then there will be three more town meetings in September, October and November, for the support of which there is doubtless abundant material in and about Manchester. We wish the movement every success.

THE GARDEN.

"This is an art
Which does mend nature: changes it rather; but
THE ART IS NATURE."—*Shakespeare.*

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER.

Readers who may find it difficult to procure the numbers regularly through the newsagents or booksellers, may have them sent direct from the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance. "THE GARDEN" is sent to subscribers by Friday evening's post.

HAMPSTEAD HEATH.

The public has every reason to be satisfied with the opportune additions to the number of our London Parks which have taken place of late years—beginning with the Regent's Park, secured to the public and laid out during the Regency; and followed, after a somewhat long delay, by Victoria Park, for the use of the extreme eastern suburbs; and Battersea Park, for the transpontine districts of the south-west. As a fitting continuation of these steps in the right direction, whatever may have been their shortcomings, we have at last, after many efforts, secured Hampstead Heath as a noble outlying park for the rapidly-growing suburbs of the north-west.

This beautiful stretch of undulating ground, from the higher portions of which a vast panoramic view of London is obtained, in the midst of which rises in misty grandeur the noble dome of St. Paul's, has been thoughtfully and picturesquely described by Leigh Hunt and several other popular writers. The scene is, in fact, well worthy of thoughtful contemplation; it is as grand as that celebrated view of Rome, with the vast dome of St. Peter's in its midst, that is obtained from the Sabine Hills, which border the far-stretching Campagna to the south-east. In fact, our Hampstead view of the great modern metropolis is far more impressive than even that of Rome from the Sabine Hills, inasmuch as from that spot we are enabled to look upon a teeming centre of human wealth and power, still in a state of rapid and unexampled progress, instead of upon one of decadence; and yet, we were very near losing the privilege of possessing a spot hallowed by a thousand historic associations, and seeing it covered by smug villas, whose Cockney gardens and their enclosing walls would have shut out the noble view for ever—at all events, during the running off of leases for ninety-nine years.

Fortunately, an Act of Parliament has secured the most picturesque piece of ground within half-a-dozen miles of London, and only just in time. For, doubtless, the "lord of the manor," in the exercise of fully-admitted territorial rights, which at present remain undisputed, would have turned it to the best account in whatever manner the most lucrative results could have been obtained, which would, undoubtedly, have been by letting out the whole space in small plots on building leases to speculative builders. This desecration has been prevented by the spirited vote of £45,000 by the House of Commons to rescue this ancient playground of Londoners from absorption by the lord of the manor and the builders.

The public, who has grown a very big, strong boy, has struggled hard for his old playground and won it, and the next thing to be considered is, "What will he do with it?" The *Times* (after blaming the delay that has taken place since the acquisition of this new public property) has very wisely suggested that plans for imparking and laying out this beautiful site to the best advantage shall be obtained at once from our most eminent landscape gardeners, and the best plan acted upon without further delay. It will require the utmost taste and discretion to manage the arrangements of the new plantations, walks, and drives, in such a manner as, while ministering to the enjoyment of the public, they shall not interfere with those wild beauties of the scene which form its most attractive charm.

NOEL HUMPHREYS.

THE KITCHEN-GARDEN.

SMALL GARDENS.

As a savings bank for scraps of time there is no institution in which the cottager, the artisan, and even middle-class man can better invest his leisure hours than in the garden; for, apart from the life-invigorating occupation which it affords, there is attached to it profit in the shape of a supply of fruits and vegetables; and the value of fresh, well-cooked vegetables, in a health-giving and sanitary point of view, can scarcely be overrated.

Passing over the essential elements, viz., light, heat, air, and moisture, without which plant-life cannot exist in a healthy state, we come to the rotation of crops. The true theory of plants not succeeding for two or more seasons in succession on the same ground is that the soil becomes exhausted of the food necessary for the particular plant; and this is proved by the practice of the London market gardeners, who manure their ground so very heavily that they care nothing for rotation. The late Rev. H. Smith, of Lois Wealdon, near Daventry, grew wheat upon the same land for upwards of twenty years without manure, but then he had an inexhaustible store of the mineral constituents of the wheat crop in the subsoil, and a small portion of this was brought up every third or fourth year to maintain the fertility of the soil; and in that way Mr. Smith considered he could go on growing wheat upon the same plot for hundreds of years. The small gardener may not have such a store of plant material to resort to, and, therefore, systematic rotation is his most certain resource. For the purpose of simplicity, and to make the rotation clearly understood, I append the annexed diagram, which we will suppose represents a plot forty yards by fifteen yards, or just one eighth of an acre.

This I would divide into four equal proportions, numbered one to four, and of the three divisional lines, the centre one should be an asparagus bed, and the two other lines, respectively, rhubarb and seakale. The marginal dotted line would be planted with fruit-trees, say, pyramidal apple and pear trees, at ten feet apart, with two gooseberry or currant trees between each pair. Around the outer margin a row of strawberries may be planted, or herbs or flowers. In each row of seakale and rhubarb three compact-headed apple, pear, or plum trees might be placed, without interfering injuriously with the under crops.

Now, in the rotation which I propose there is one special provision that must be made, and it is this: Never sow peas or runner-beans nearer together than eight to thirteen feet apart; and in this way, as each division of the plot is thirty feet wide, two rows of these vegetables may be sown in each, without the same crop coming upon the same land more than once in five or seven years. This will give eight rows, or seven successive crops of peas and one of scarlet-runner beans, which will be ample for any ordinary family. These crops arranged, the next consideration is the rotation, and those crops we divide under three heads, viz.—*Deepeners, Improvers, and Exhausters.* Thus, No. 1 will be cropped with celery, carrots, parsnips, and onions, all of which require a deeply-trenched soil; a catch crop of radishes, lettuce, and a row or two of early cauliflowers, being taken before the celery need be planted. No. 2 will have cabbage, cauliflowers, turnips, and spinach, followed by coleworts (small cabbage) directly the other crops are removed. No. 3 will contain broad beans, leeks, and early potatoes; these crops being followed by savoys, curled broccoli, Brussels sprouts, and similar winter greens. No. 4 will be stocked entirely with late potatoes in rows three feet apart, interlined in July with winter broccoli or other brassicas; broad beans may be dropped in with the potatoes at a yard apart, from which a fine crop may be gathered without injury to the potato crop. Here, then, we have the whole ground cropped for the first year. In the following season I will take the place of 4, while the other crops will advance one step forward; and this round of cropping will continue as long as may be thought proper. No system of cropping can be more simple and systematic, and I speak the result of nearly forty years' experience when I say no system of rotation can be more profitable.

As regards cultivation, let us assume that the garden has been properly drained, not less than three feet, and, if possible, four feet, deep, the drains being from fifteen feet to twenty feet apart. Then the ground must be trenched two feet deep, not necessarily reversing the ground to that depth, but digging the surface a foot deep, and loosening the subsoil another foot, so that it may become enriched from the percolation of the manure-water from the surface, and be

ready for bringing up in subsequent trenching. Trenching may be defined as reversing the whole body of soil two or more feet deep. Bastard trenching consists in digging the surface soil a foot deep, and moving the subsoil another foot, but leaving it there. Sometimes a layer of dung is placed between the two layers of soil: a very good practice for deep-rooting plants. Digging or forkings is simply the reversal of the surface-soil to the depth of one foot; and in performing that operation, it will be found a good practice to pare off two or three inches of the surface soil, and place it in the bottom of the trench, so as to bury the weed-seeds beyond vegetative distance.

As respects manure, in addition to farmyard dung, finely-sifted ashes, soil, weeds—in fact, vegetable refuse of all kinds—may be collected together, and if regularly soaked with sewage, will soon become rich manure. Thus, several cartloads may be collected in the course of a year, and will add materially to the fertility of the garden. If the soil is light and sandy, salt may be used with considerable advantage; but if heavy, then lime, or lime and salt will be preferable. Of concentrated manures, Peruvian guano, if it can be procured genuine, is the best, especially for making manure-water. Nitrate of soda is a valuable manure for light land, and sot may be strongly recommended for heavy soils.

With reference to cropping, the following remembrance was compiled nearly thirty years ago, and the fact that it has stood the test of that length of time without change or amendment, is the best proof of its value:—

	Sow	SEED-TIME.								
		JAN.	FEB.	MAR.	APR.	MAY	JUNE	JULY	AUG.	SEPT.

Pot Herbs		2	2	2						

Note.—The figures refer to the weeks in each month; in early situations sow the early, and in late, the latter part of each respective week.

Sow everything in drills, whether in seed-beds or as permanent crops. Small seeds such as onions, carrots, &c., in addition should be dibbled in the drills; half the usual quantity of seed will thus be sufficient. Avoid broadcast sowing altogether. It is not necessary to manure for every crop; carrots and parsnips are better without it; but broccoli, cauliflower, and all the brassicas should be plentifully supplied with it, solid and liquid. The first and last crops of tender varieties of vegetables, as peas, cauliflower, French beans, lettuces, radishes, should be sown in sheltered situations. To render the succession of vegetables certain, sow two or three varieties at the same time.

The following list of select vegetables may be of use in these days when seedsmen's catalogues are so overburthened with varieties:—

ASPARAGUS.—Of this there is but one kind. The Giant is only a stronger sort.

- BROAD BEANS.—Royal Dwarf Cluster, Broad and Green Windsor. BEET.—Pine-apple, Short Top, Barr & Sugden's New Crimson. BRUSSELS SPROUTS.—Sutton's and Scrymer's Giant. BORCROFT.—Hearting Cottager's Kale, Bude or Asparagus Kale. BROCCOLI.—Snow's Winter White, Hammond's Imperial Hardy, Cattell's Eclipse, Carter's Late Summer, Potts Sprouting. CABBAGE.—Atkins's Matchless, and Rosette Colewort, for all seasons. For larger kinds, Wheeler's Imperial and Enfield Market. CARROT.—Early Scarlet Horn, Intermediate, and Altrincham for deep soils. CELERY.—Incomparable, Hooley's Conqueror, for size. CUCUMBER.—Telegraph, Master's Prolific, Hardly Ridge. ENDIVE.—Frazer's Improved Batavian, Diggswell Prize. KALE BEANS.—Sion House, Newington Wonder; Scarlet Runner—Carter's Champion. LEEK.—Aylton Castle. LETTUCE.—Hardy Hammersmith, All the Year Round, for winter; Tom Thumb, Cos, Stag's Loaf, Dunnett's Perfection, White Paris Cos. ONION.—Hardy, for autumn sowing, Red and White Tripoli; summer crop, White Spanish, Globe, James's Keeping; for pickling, Silver Skinned. PEAS.—Garden, Ringlet, Advancer; main crop, Yorkshire Hero, Veitch's Perfection, No pins ultra. PARSLEY.—Treble Curled. RADISH.—Wool's Early Frame, Short Top, Scarlet and White, Olive Shaped, Red and White Turnip. RHUBARB.—Dancer's Early Scarlet, Myatt's Victoria, Mitchell's Royal Albert. SPINACH.—Flanders and Prickly. STONE.—Bacon's Stone, White Strap-leaved; Chirk Castle and Orange Jelly, for winter. POTATOES.—Veitch's Asplen, Myatt's Ashleaf, Haig's Kidney, Paterson's Victoria and Economist, Milky White, Baron's Perfection, Almond's Yorkshire Hero. VEGETABLE MARROW.—Hibberd's Prolific, Moore's Cream, Prince Albert.

A few notes upon vegetables may not be out of place. The Royal Clusters Dwarf Bean is valuable, forming a plant about a foot high; and the same may be said of Newington Wonder French Bean. Carter's Champion Runner is invaluable, being nearly double the size of the ordinary runner. Among brassicas we attach great importance to Snowy's Broccoli; it is invaluable, and so is Hammond's Imperial for spring use. For cottagers, Purple Sprouting is very profitable, and has the true broccolli flavour. Let me strongly recommend the asparagus, or Buda-kale, for spring use, it is one of the finest vegetables we have. A good word must also be said for the Rosette Colewort. There should always be a seed-bed of this ready for filling up every vacant space.

THE LARGE WHITE CALIFORNIAN RADISH.

THE fact that some imperfect specimens of this have received a first-class certificate from the Royal Horticultural Society justifies some allusion to it. It was when walking through the Chinese quarter of San Francisco, in the beginning of November 1870, that I first saw it. Among the various vegetable products which were exhibited outside the Chinese shops was what seemed to be a peculiarly tender-looking white turnip, with a skin as smooth as glass, and pure white. The roots were cylindrical in outline, but usually rather neatly rounded at the ends, somewhat like a cucumber, and they were from eight to twelve inches long, and from two-and-a-half to three-and-a-half inches in diameter. Certain that it was a distinct and excellent kind of turnip, I made some inquiries as to the variety, and learnt that it was a radish. But, surely, a radish of such size must be a tough subject in the centre! On the contrary, the largest specimens were found to be as tender throughout as a well-grown young summer turnip. I afterwards visited the gardens where these radishes were produced, and found them grown, and thoroughly well grown too, in beds about four feet wide, with a narrow alley between. The plants, arranged in lines, had abundant room to grow, and seemed to have thriven unchecked in the sandy soil, kept well moistened and enriched by the Chinese gardeners. The culture seemed to me remarkably like what one sees in a good market-garden at Paris, the only difference I saw being, that between every two lines of plants there was a little hollow scooped out, and in this a small drain of half-decomposed manure was placed. Specimens bought in the Chinese market at San Francisco, and brought to London with other seeds and roots, maintained their freshness and good flavour for many weeks. They were shown to some of the most experienced seedsmen and growers in London, not one of whom ever suspected they had anything to do with a radish, though they employed the tongue as well as the eye test. Where these radishes are grown so well, the winter climate is much like that of our early autumn, so they do not suffer from cold. The tops of the specimens shown at South Kensington were dead from frost.

The plant must, of course, receive the treatment of an autumn and winter radish, and be sown in rich, light, and warm soil. In the colder parts of the country it might be desirable to place some plants in positions where they could be readily covered by a ground viney or some such protection, so as to prevent their being checked or destroyed by autumnal frosts. If it prove distinct, it will doubtless be an acquisition.

W. R.

THE FLOWER-GARDEN.

THE HARDY BAMBOOS.

THERE are no materials more attractive than these for the embellishment of pleasure-grounds in the southern and milder districts. I have grown and admired the beautiful and graceful *Bambusa* (*Arundinaria*) *falcata*. It is one of the most valuable of all plants for dotting here and there in the pleasure-ground, on islands, near water, or in the rougher parts of the rock-garden or hardy fernery. When once established it is surprising to see the number of vigorous young fishing-rod-like shoots that spring from it every summer. With me they used to attain a height of from fifteen to twenty feet. I have had hundreds of canes an inch in diameter at the base, springing from one tuft. At Bicton we had them very fine associated with the Pampas grass and *Arundo Donax*, particularly by the sides of streams, and in sheltered and half-shady nooks of the rock-garden. The best and handsomest plants of this bamboo I have ever seen are at Mount Edgecumbe. The most important consideration in connection with this pretty well-known plant, however, is that at least several other species of hardy bamboo are very likely, indeed, to prove as hardy, if not harder, than the subject of our illustration. For example, I find the following descriptions of good kinds in "The Sub-tropical Garden":—

BAMBUSA JAPONICA (*B. Metake*).—A large-leaved and rather dwarf species from Japan, growing from four feet to seven feet high, with erect, thickly-tufted stems, which are entirely covered by the sheaths of the leaves; the branches are also erect. The leaves are lance-shaped, with a very sharp point, dark green, persistent, narrow-edged into a short leaf-stalk, and nearly a foot long. This species sometimes flowers with extraordinary profusion at the expense of a portion of the foliage, which withers away and leaves the naked stems exposed. This may, however, be prevented, to some extent, by placing the plants on mounds somewhat above the level of the surrounding soil. I have seen it thrive very freely in the late Mr. Borrer's garden in Sussex, and in one or two other places. It loves a peat soil, or a very free moist and deep loam, and runs a good deal at the root.

BAMBUSA MITIS.—A fine and vigorous kind from Cochin China, somewhat tender than most of the other kinds enumerated, though no doubt it will be found to thrive in the milder southern districts; or it may be found useful if grown in the conservatory in winter and planted out in the open air in summer, as is sometimes done with *B. arundinacea*, which otherwise could not possibly be seen out of doors in our climate. Panicle simple, erect, close; spikes long, imbricated. Leaves rather large, lance-shaped, striated, clasping the stem, which is woody and tapering; nodes rather distant, and not very prominent.

BAMBUSA NIGRA.—A rather compact-growing Chinese kind, with nearly solid stems, and thinner leaves than those of any other species.

The stems are smooth and bushy, about seven feet high, of a light green, dotted and striped with purple when young, changing to a glistening black when fully grown; they branch very much at the top, and sometimes from the base up. The leaves are oval-oblong, acute, shortly-stalked, with a hard, dry, persistent sheath; their tender green colour contrasting finely with the blackish hue of the stems. It is best planted as isolated specimens near the margins of shrubberies, or on slopes in the pleasure-ground in warm, sunny, and sheltered positions, in deep, sandy, and well-drained soil.

BAMBUSA QUILIOI.—A Japanese species of vigorous growth, with robust green stems and bright-green leaves, polished above and slightly mealy beneath, the ligule bearing a little bundle of brownish-grey hairs on the top. This kind I first saw in the gardens of the Acclimatisation Society at Paris, where it was thriving vigorously, and I have little doubt of its proving valuable in Britain.

BAMBUSA SIMONII.—A handsome, distinct, and vigorous species, which has grown very freely for some years past in the neighbourhood of Paris. The stems are numerous and grow as much as ten feet high in a season. They are mealy-glaucous at the joints, and the branchlets are numerous and rather closely crowded. The leaves

are narrow, sometimes nearly a foot long, and are occasionally striped with white. This species, which was obtained from China some years since, has thriven very well in the gardens at Paris, where M. Carrère first drew my attention to it. From what I have seen it do there I have no doubt it will prove of great value in the milder southern parts of England and Ireland.

BAMBUSA VIOLACEA.—A hardy and vigorous kind, intermediate between *B. nigra* and *B. viridiglaucescens*, most resembling the last-mentioned however. It has blackish-violet much-branched stems, which assume a yellow tinge with age. The leaves are green above, bluish-grey beneath, with an elongated ligule surrounded by a bundle of black hairs. Native of China.

BAMBUSA VIRIDIGLAUCESCENS.—A species from Northern China, which has been proved very hardy and free in the Paris gardens, and will, probably, in warm parts of our islands, make a more vigorous growth and prove a more beautiful object than any other kind. The stems, of a light-yellowish-green, grow from seven feet to twelve feet high, branching from the base, each branch again branching very much. The leaves are very numerous, especially at the ends of the branches, of a pale-green, bluish underneath, sheathing the stem for a considerable length. It forms a fine object when planted as isolated specimens in sheltered warm glades in the pleasure-ground, or in snug open spots near wood-walks, in very deep, rich, light, and well-drained soil.

All the above, with one exception, I had the pleasure of seeing about Paris in 1867. Several of them were more vigorous than *Bambusa falcata*, growing in the same ground; hence a very good reason for believing that some of them will be found of quite as great importance as the one figured, and which has been proved to add such a charming feature to many gardens in the southern and western England and Ireland. We are indebted to M^r Andrieux, & Co., of Paris, for the above ad: well-grown specimen of *B. falcata*.

Bambusa (*Arundinaria*) *falcata*

A PLEA FOR ROCK GARDENS.

BY JAMES McNAB, ROYAL BOTANIC GARDENS, EDINBURGH.

ROCK GARDENS may be looked upon as comparatively modern institutions, while rockeries are of ancient date. The latter are excellent in their way, but depend much on the nature of the material at the command of the operator, and on being constructed in such a manner as to produce a landscape effect. In rockeries the suitable and geological arrangement of the material is generally aimed at, more than a scientific or artistic distribution of the plants intended to be grown. But with rock gardens, on the other hand, the arrangement and formal distribution of the plants are specially to be considered. It is, however, not necessary that artistic effect should be laid altogether aside, for it is quite possible to have a graceful arrangement without sacrificing the individual health and habit of the plants. For a long series of years I have been enamoured by the diversified forms and extreme beauty of alpine plants, having always had under my charge a large number of these deserving favourites. Their cultivation, however, had always been in pots, plunged in ashes in raised pits, covering with glass during the winter months when necessary.

Some years ago the removal of a high wall which separated the botanical from the old experimental garden here became necessary, to throw the two establishments into one. To utilize this large portion of old building material I commenced what I called a rock garden; in contradistinction to the rockeries which I had previously seen in many places throughout the country, where alpine and herbaceous plants, shrubs, both evergreen and deciduous, and often trees, were indiscriminately growing together, the stronger and wider-spreading plants often smothering the weaker. The general effect of such rockeries when judiciously constructed was good, particularly in the eyes of people not having a botanical taste. In the construction of the rock garden here, I got the stones of the old wall just alluded to split up longitudinally, and arranged on a piece of sloping ground facing the north, which I had previously laid out in an undulating and somewhat geometrical form, and which I divided into uniform sections, separated by stone paths and steps. These sections were then divided into angular compartments of various sizes, and each filled with soils suited for the various plants to be put into them. The compartments of several of the sections were afterwards filled with various species of a genus, such as the sections of *Sempervivums*, *Sedums*, *Saxifragas*, also of *Primulas*, *Silenes*, *Aubrietas*, *Gentianas*, *Androsaces*, &c. Other sections were filled with plants of a uniform height, particularly of kinds of which only a few species exist, while others were arranged in geographical order. The success of the early part of this experiment was such as to induce me to transfer a very large proportion of our alpine plants to the rock garden; and I am happy to say that I have never had cause to regret it. It was often a difficult matter to get such a large collection of alpine plants as existed here kept in proper order, particularly when confined under pot culture, the attention necessary for shifting such a collection being often more than it was possible to undertake at the proper season with a limited staff of men. Unless such re-potting was regularly gone into, the foliage and flowers of each could not be properly developed. In this state, species often get confounded together, which is not likely to be the case when all are planted in separate rock-work compartments, yet near enough to be easily compared. The various sections of a rock garden, having the soil prepared specially for the different genera, should be equally drained and enjoy the same exposure. Under such auspices, each individual plant is developed in a more perfect condition than it can possibly be under ordinary pot culture; but, of course, if anyone could devote a great deal of care and attention to a few select favourites, they might develop very superior specimens by pot culture.

The rock garden recently constructed at the Edinburgh Botanic Garden, and still in progress of extension, contains upwards of four thousand compartments, of which 2,200 spaces are filled with various species and varieties of alpine and dwarf-herbaceous plants, besides numerous dwarf, shrubby kinds, from all temperate parts of the globe. The remaining

compartments are filled with free-flowering duplicates, placed at uniform distances, to please the eye of those whose taste is more for colour; but even to the botanical cultivator, such free-flowering duplicate masses cannot be otherwise than extremely interesting.

All the angular interstices between the irregular plant compartments are filled with a selection of bulbous plants, such as species of *Triteleia*, *Calliprora*, *Calochortus*, *Cyclobohra*, *Cyclamen*, white *Sisyrinchium grandiflorum*; and amongst them nothing more pleasing than the *Iris reticulata*, which thrives well in such places and flowers abundantly. It never requires to be lifted except for sub-division.

Many of the larger compartments between the miscellaneous collection of alpines are filled with a selected collection of spring-flowering bulbous plants, such as the Crimean Snowdrop, all the varieties of *Scillas*, of which *S. bifolia major* and *S. sibirica* predominate; *Puschkinia*, varieties of the Grape Hyacinth, Vernal Snowflake; *Bulbocodium vernum*, dwarf *Narcissus*, &c. After the spring bulbs are done blooming and cut down, a little good soil is placed on the surface, and the spaces are filled with dwarf annuals, and shallow-rooted summer-flowering herbaceous plants, such as *Leptosiphons*, *Clintonias*, dwarf *Gilia*, *Mesembryanthemum tricolor*, *Holosteum umbellatum*, *Myosurus minimus*, *Limaria alpina*, *Papaver alpinum*, dwarf *Lobelia*, *Alstermeriantha*, &c. Such plants are all removed as soon as injured by frost, and the surface of the bulbs is again covered with a little fresh soil, in order to protect the seeds of the annual plants, which rarely start till the bulbous plants are over. It will be found, after the expiration of two or three years, that some of the bulbs will get into a tufted condition, preventing their free flowering. With such plants it will be necessary, as soon as their blooming is over, to have them lifted and sub-divided, giving fresh soil where necessary, and replacing only the larger or flowering bulbs.

Besides the choice bulbs planted in the general rock-garden compartments, a large division is also set aside for a general collection of all the spring-flowering bulbous plants, both species and varieties, and which are exceedingly interesting during the early months. A division is also arranged for *Colchicums*, of which the red, pink, white, and variegated contrast well with the varieties of autumn-flowering *Crocus*, particularly the *C. speciosus*, which succeeds admirably in the stone compartments, making quite a show during the months of September and October.

Large divisions are also appropriated for a selection of monocotyledonous plants, exclusive of bulbs, such as the dwarf and herbaceous species of *Iris* and *Yucca*; also species of *Cordyline*, *Sparaxis*, *Helonias*, *Ophiopogon*, *Trillium*, terrestrial orchids, *Convallaria*, *Uvularia*, *Narthecium*, *Tofieldia*, *Acorus*, rare species of alpine *Carex*, &c.

The interstices between the upright stones are filled with varieties of *Primula vulgaris*, both single and double, which flower abundantly. The double-flowering sorts, which hitherto were of difficult cultivation in the open air, succeed in such places remarkably well. *Hepaticas* are also admirably adapted for such situations, and, with the *Primulas*, have a gay appearance during the spring months.

The rock garden recently formed here is 190 feet long and at present 85 feet wide, having a uniform and graduated elevation of 12 feet. The extension and elevation of the rock garden is still progressing, and when completed the ultimate proportions will be 190 feet long, 120 feet wide, and the ultimate height, 18 feet. In the construction of the rock garden, care has been taken to have it all thoroughly drained. The soil, as well as the sandy subsoil, has all been thrown up, and the ground below filled with ashes and foundation rubbish, composed of stones and other rough material, of which quantities can always be had near large towns for nothing. The original surface soil is always kept uppermost, for placing the stones in. These stones vary from 14 inches to 3 feet in length, from 8 inches to 10 inches in breadth and from 3 inches to 4 inches in thickness, having more or less angular tops. They are all placed about 10 inches or 12 inches deep in the soil in an upright position, not "sloping at a high angle to the east," as stated by "G. A. L." in the *Gardeners' Chronicle* of the 14th of October, 1871.

Angular stone stumps, varying from 3 feet to 9 feet in circumference, and from 1 foot to 3 feet in height, are placed on prominent points at uniform distances. Each stone stump is planted with Yuccas and Cordylines. The sides of these upright stone stumps are furnished with angular buttress-stones, which gradually join into the ordinary stone compartments. These stone stumps, filled with large and formal plants of *Yucca gloriosa*, *Y. recurva*, &c., tend to give a characteristic and decided look to the rock garden.

After all the stone compartments are arranged, the ordinary garden soil is taken out, and is replaced by prepared compost, chiefly consisting of turfy loam, peat, and sand; in proportions to suit the plants intended for them. I consider freestone, or any kind of sandstone of a free-splitting character, to be the most suitable, as roots take kindly to it. Besides, such stones retain a considerable deal of moisture when under the surface of the ground, thus giving a certain degree of nourishment to the roots during dry weather. When lifting plants that have been thus treated, the roots will be found to adhere to the stone all round, and can thus be taken up for transplanting in square, triangular, or septangular masses, as the case may be. The drainage before alluded to proves very beneficial during the winter months, as is evidenced by the large number of plants which can be wintered with impunity on the elevated slopes of this rock garden, when contrasted with many of the same species planted in the ordinary garden borders, where they generally decay away with frost and damp. The fact of frost not affecting plants on an elevated rock garden to the same extent as when planted in open borders was thoroughly tested during the winter of 1870-71. The frost set in early in November, and from that period up to the end of February, making 120 days, the thermometer in the garden registered below the freezing-point on no less than seventy-three mornings. During November 1870, on twenty mornings the lowest points were on the 2nd, 8th, 9th, 10th, 22nd, and 23rd, indicating, respectively, 29°, 26°, 25°, 29°, 27°, and 26°. During December, on eighteen mornings, the lowest points were on the 16th, 23rd, 25th, 27th, 28th, and 31st, indicating, respectively, 26°, 9°, 20°, 12°, 17°, and 20°. During the month of January 1871, the thermometer fell no less than twenty-seven mornings below the freezing-point, the lowest being on the 21st, 24th, 25th, 26th, 27th, and 28th, indicating 20°, 22°, 21°, 21°, 16°, and 14°. During February, on eight mornings, the thermometer was below 32°, the lowest being on the 1st, 2nd, 11th, 12th, 13th, and 26th, indicating, respectively, 26°, 30°, 31°, 29°, 29°, and 31°. Although this long-continued frost, almost without snow, penetrated full thirteen inches into the rock garden, it was surprising to find that, when genial weather returned, very few plants had suffered.

At some future time, when the rock garden is nearer completion, it will be my endeavour to give drawings and further details of it—then the large Araucarias and Yuccas, which now adorn all the prominent points, will be more matured. Meanwhile, I hope enough has been said to give an impetus to the further cultivation of alpine plants on the rock-garden system. Rock gardens can afford as much scope for the display of a geometrical or fanciful taste as any of our modern bedding-out flower-gardens, particularly now that mixed summer bedding-out flower-gardens are coming more into fashion. A geometrical rock-work and flower-garden combined was constructed during 1870 at Easton Duddingston Lodge, the residence of Charles Jenner, Esq., and is a good instance of this novel style of gardening. The raised geometrical beds have their sides constructed of a series of sloping stone compartments for the growth of alpine plants, while their raised centres during spring are filled with bulbous plants, and are afterwards replaced with a methodical arrangement of summer-flowering bedding plants.

On the property of William Christie, Esq., of Craignell Park, near Edinburgh, an old quarry has been turned to good account for rock-garden purposes. When confined entirely to the rock as quarried, a difficulty frequently occurs of getting proper places excavated, for the reception of plants. Mr. Christie has successfully combated this difficulty by laying out the interior in portions of various sizes and styles, composed of stone compartments, for the reception of alpine plants.

Another rockwork, but more in the rock-garden style, has been in process of formation for several years on a piece of southern sloping ground at Fettes Mount, near Laswade, the summer residence of G. H. Potts, Esq. It is laid out in terraces, a style peculiarly well suited to the naturally sloping character of the ground on which it has been constructed.

In many parts of Argyllshire, villa residences have been fixed on merely on account of the natural rocks existing on the ground, which are afterwards covered with ferns and other rock-work plants.

In the construction of rockeries, as well as rock gardens, it is necessary to provide the means of watering during dry weather; for this purpose a flexible tube and hose will be found the most efficient means. Of course, a force of water from a high reservoir is indispensable.

AMARANTUS SALICIFOLIUS.

THIS promises to be the finest-foliated plant for dinner-table, drawing-room, and garden-decoration for 1872. It created some thing like a *furore* wherever exhibited last season. It is impossible to exaggerate its beauty, or exhaust its grace, by pen or pencil sketches. It is a free-growing plant, of admirable habit, forming a dense weeping pyramid of about a yard high, and nearly as much through. The plants shown at South Kensington were reported to have been grown in the open ground, from whence they were lifted into pots, and removed to the show. Everything else looked common-place beside them; they were the eye of the exhibition. Long, narrow leaves, from a quarter to half an inch wide, and from six to twelve inches long, weeped down over each other and the pots in the most graceful manner. They exhibited every hue of colour, from bronze-green to the most brilliant orange-red. It seemed as if more than all the beauty of *Croton angustifolium* and *C. interruptum* were combined in this charming Amaranth, or whatever else it may be; for I see its title is already questioned; and it certainly is like no other Amaranthus.

But be it what it may, it is a rare gem for decorative purposes. For centres, groups, or rows, massed either by itself or as a set off to other flowering or foliage-plants, it is likely to prove invaluable. In baskets, on brackets, or in vases, in conservatories or living-rooms, I cannot conceive anything more rich and elegant; while it will obviously give a new character to dinner-table decoration. Those long pendent branches, terminating in brilliant plumes, will fit in admirably with, and enhance the richness of, the finest services of plate, glass, dessert, &c. And to cut for the furnishing of tall vases, who that has seen it does not long to have such masses of drooping beauty with which to enwrap and elegantly dress them? Does any one think this the language of exaggeration? then let him hasten to see and grow the plant for himself.

D. T. F.

Modern Flower Gardens.—Mr. Henry Kingsley has undertaken the herculean task of reforming our modern flower-gardens. Everybody must admit that we have too little individuality—that we are too much ruled by fashion, and if Mr. Kingsley can help us to break through its trammels he will do good service. Most men when they propose a scheme of disestablishment—whether it is that of a church, a government, or a garden—have some scheme of their own to put forth as a substitute; and, as far as I understand Mr. Kingsley, he is desirous of reverting to a more natural style of gardening than that which is now practised. Byron says, "There is a pleasure in the pathless woods"; and I must confess that sometimes, after being half-blinded by the glare of a garden that had taken thousands of plants to fill it, I should have felt, like Byron, delighted with the pathless woods, or with Mr. Kingsley's garden *au naturel*. We have been trying to out-do each other in our rage after novelties. We have even scaled the house-top and torn off the housetop to plant in lines on mud, so feelingly described by Mr. Kingsley. Nevertheless, after the everlasting red-white-and-blue pattern, the succulents were a move in the right direction. I am not over anxious about seeing them all in a line, which so irritated Mr. Kingsley, but I believe true flower-garden reform lies in the direction of making a freer use of hardy plants, of neutral tints of foliage and flowers, to tone down the bright colours. I should be only to glad to enthrall our present bedding-out system. I don't think we can do without it till the fashion changes, but by making larger use of hardy plants, many of which are especially adapted for massing, we shall be able to free our houses of thousands of the usual subjects of bedding-out.—E. HOBDAY, Ramsey Abbey, Hunts.

THE SEA HOLLIES (ERYNGIUM).

(Continued from page 50.)

Of quite a different type is the next species that claims attention, viz., *E. aquifolium*, a fine, bold border plant, attaining a height of some three or four feet, or even more, with a general contour of a candelabrum-like character. As a proof of its classic character, I may add that in the Exhibition of 1851, Messrs. Hunt & Roskell took the design for one of their most recherché candelabra from an almost perfect facsimile of a flowering stem of this plant; and, by way of securing the pattern from decay, they electro-plated the plant itself.

In succession to the preceding we have a group that is so closely allied that, for all general purposes, its constituents may be considered under one head: *Eryngium planum*, *E. glomeratum*, *E. crticum*, and *E. virgatum*. In all of these the radical leaves are elliptic in shape, and of a bright, shining green colour. The much-branched stems rise to a height of three feet, with the globose inflorescences varying in size in the several species. The involucral leaves are narrow and spinous, and the beauty of the plants depends more on their elegant habit of growth and the general bluish hue, which gives a peculiar charm to the various ramifications, than upon anything else. These plants all seed freely, and in this way may be increased to any extent. I ought to add, however, that the seeds of *Eryngium* rarely vegetate the first season, and, therefore, ought not to be discarded, as they too frequently are, before they have experienced the influence of a second spring's sun.

So much for the entire-leaved section. In our second group, first on the list unquestionably stands *E. amethystinum*. With the radical leaves three-parted and flower-stems moderately branched, rising to a height of two feet or more, and producing numerous stems, the whole suffused with a steel-blue colour, its specific name is in the highest degree appropriate; and a beautiful plant it is.

Closely allied to it, but much larger and stronger in growth—a remark which also applies to its involucral heads of flowers—is the Himalayan *E. Roylei*. This species sometimes attains the height of four or five feet, and is of robust growth, but rarely matures its seeds—at least, such has been my experience.

Two slender and peculiarly forked species, viz., *E. corniculatum* and *E. corniculatum*, the former growing about two feet high, the latter about nine feet, it will suffice merely to name as desirable and distinct, where a collection rather than a selection is the object.

E. spina alba, which is usually entitled *E. rigidum*—but so appropriate is its older title that I prefer reversing the order of synonymy—is a dwarf plant, native of the south of France, of peculiarly rigid aspect, and covered with long projecting white spines, whence the name. It is a species but rarely met with, and, as cultivated by me, does not appear to be long-lived, usually exhausting its vitality by the third year.

Two species, viz., *E. Bourgatii* and *E. Balbisii*, closely allied, if not absolutely similar, are both well worth cultivation. Dwarf (rarely exceeding fifteen inches in height), they have undulated and divided radical leaves, marbled over with white; and though devoid of any brilliancy of floral colour, the character just alluded to, and their general habit, is sufficient to give them a claim to the front rank of the herbaceous border.

The third group contains several species all of great similarity of aspect, and all coming from the Southern States of America or Mexico. Unlike the heretofore enumerated species, they have long and somewhat Yucca-like leaves.

E. yuccafolium (syn., *E. aquaticum*), *E. bromeliaceum*, and *E. virginianum* are all that I have ever met with in cultivation. So like indeed is the second species to a *Bromelia* that I have several times had it sent to me as one. A nip of the leaf between the teeth soon tells to what order it belongs by the presence of that flavour peculiar to all the Umbellifers.

These species are scarcely hardy enough to stand the vicissitudes of our climate; and, if I mistake not, have naturally a good deal of the biennial character about them. Their interest is more botanical than general. To such as have an opportunity of cultivating them, I may say that their native habitat is swampy ground; but if grown freely under similar circumstances in this country they are almost certain to be cut off by an early frost in winter, whereas if grown in a somewhat dry, sheltered nook of a rockery they are much more likely to survive the perils of their first winter, and to flower sufficiently early in the season to render the maturation of their seed possible, at least, if not probable.

Hull Botanic Gardens.

JAS. C. NIVEN.

God manages all of nature's growth and bloom in such way, that every earnest man with an observant eye can so far trace the laws of His Providence, as to insure to himself a harvest of fruit, or grain, or flowers. And whatever errors may be made are only so many instructors, to teach, and to quicken love by their lesson.—IK. MARVEL.

NOTES AND QUESTIONS ON FLOWER-GARDENING.

Iris persica.—Professor Syme informs us that this charming plant proves hardy under a wall as far north as Fifehire, and that it flowers there every spring.

"Carpeting" Ground beneath Trees.—I have recently taken a cottage in Derbyshire, as a refuge occasionally from city smoke and fog. There is a garden of fair size, in which are laurentius, yew, holly, and other evergreen trees, which have been planted and long neglected, and are now of large growth. I like them as they are, but there are such big bare spaces of earth below them on which nothing grows—not even weeds. Will anything grow there, and "carpet" the soil?—J. S.—[Your best plan is to naturalize on the bare ground small herbaceous plants that thrive in similar positions. Try, for example, the winter aconite, the periwinkles in considerable variety, the blue aconine, and the wood anemones, the St. John's Wort, the snowdrop, and any kinds of crocus or daffodil you can readily obtain.]

Flowers.—Some fifty years ago the poet Goethe discovered that all the parts of plants had a kind of common nature, and would change to each other. Now, as we all know, the leaves of a plant will grow roots, and, in fact, all plants are composed of essentially two parts—the leaf and root—one loving the light, the other darkness; one liking to be clean, the other to be dirty; one liking to grow for the most part up, the other for the most part down; and each having faculties and purposes of its own. But the pure one which loves the light, has, above all things, the purpose of being married to another leaf, and having children; and children's children, and leaves, to make the earth fair for ever and ever, to let them, when they put on their winged robes, and are more glorious than Solomon in all his glory, and to have feasts of honey and we call them "flowers."—John Ruskin, in "Fors Clavigera."

Advice to Amateurs.—If your notion of country enjoyment is limited by thoughts of a good place where you may lie down under the trees, and frolic with your children, or smoke a pipe under your vine or clambering rose-tree at evening—find a gardener who is thoroughly taught, and who can place upon your table every day the freshest and crispest of the vegetables and fruits of the season, leaving you no care, but the care of bills for superphosphates and trenching. I like them as they are, but there are such big bare spaces of earth below them on which nothing grows—not even weeds. Will anything grow there, and "carpet" the soil?—J. THE IN-DOOR GARDEN.

PALMS FOR THE GARDEN.

(Continued from page 31.)

Areca monostachya (Australia).—Quite a gem in its way, with a stem one-and-a-half inch in diameter and four feet high; fronds, dark-green, two feet long, drooping; useful for a vase; succeeding well under greenhouse temperature, and, in a young state, suitable for a Wardian case, being slow in growth.

A. rubra (Mauritius).—A very graceful species, having dark-green foliage, with a tint of red on the margin of the pinnæ; but the older the plant the less conspicuous the red hue becomes; leaf stalk, clothed with dark scales; habit, gracefully spreading, light and featherly; suitable for table decoration, and one of the best for general stove purposes.

A. furfuracea.—A variety of *rubra*, from which it differs in the absence of the red tint, and in having a denser clothing of dark scales on the petiole. A variety called *A. surae* has the habit of this plant, but it has a yellowish tint on the petiole and yellow spots on the pinnæ. A handsome plant, but shy, and very fond of heat.

A. sapida (the cabbage-palm of Norfolk Island).—A useful greenhouse plant, with dark-green, narrow foliage, having a yellow tint; habit, spreading, which unfit it for table decoration, but on a pedestal it has a fine appearance. Being dwarf in habit, it is useful for the ornamentation of the conservatory.

A. triandra (East Indies).—In habit allied to *A. sapida*, but, not being so hardy, is of less value.

A. tigillaria (East Indies).—A spiny species, elegant in a young state, and pushing offsets from the base; not a free grower. *A. horrida* resembles this species; but both become ragged as they get old, and both like a high temperature.

Acrococia sclerocarpa (syn., *macrocarpa*; Tropical America).—A nice plant when young; foliage dark green, and petiole clothed with long dark spines; when large, ungainly and lax in habit; not a good plant for general purposes.

A. lasiospatha.—Similar to the above.

Astrocaryum rostratum (syn., *mexicanum*: Tropical Amer.).—A very spiny plant, with fine fronds of a dark-green hue; under sides white; stem clothed with very strong black spines, and the petiole with smaller ones; fronds dense, and pinnae broad; a good stove palm, whose spines, however, are apt to tear other plants that may happen to be within reach of them.

Arenga saccharifera (Sugar Palm; syn., *javanica*, Westerhantii: Indian Archipelago).—Fronds pinnate; when fully grown, twenty feet long and four feet wide; under side, white; upper, dark green; leaf-stalks round, with abundance of black fibre at the base. A fine palm for a large house; but quite unfit for general purposes.

Atalea cohune (Honduras).—Fronds erect, twelve feet long; pinnae channelled on under side; bright green. In this species the fronds stand without order, which gives the plant a confused appearance. For ordinary purposes, Ataleas are not very satisfactory; but where a plant is required to stand in a corridor, or near a wall, some of them might be found useful.

A. nucifera (Now Granada).—A more lax plant than Cohune; pinnae narrow.

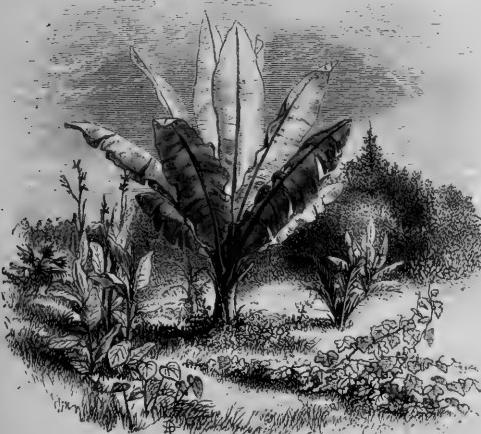

A. spectabilis (Brazil).—Fronds more spreading than in the last; margin of pinnae furnished with brown fibre, and the points are drooping. There are several other species of this genus; but they are not ornamental.

J. C.

(To be continued.)

MUSA ENSETE FOR THE CONSERVATORY AND WINTER-GARDEN.

COMPARATIVELY few have any conception of the value of this superb plant for the conservatory, large greenhouse, or winter garden. When I went to Paris in the spring of 1867, I was

Musa ensete.

pleased and surprised to find a noble specimen in one of the cool-houses there, as in England I had not previously noticed it in a cooler house than the palm-stove at Kew. Much as it has been spoken of during late years as an ornament for the flower-garden in summer, its value in this country will be indefinitely greater as a cool or intermediate house subject; particularly as in all but the southern and mild districts it may not be placed in the open air without danger. In the conservatory it quite surpasses all other plants in the stately beauty of its colossal leaves, and gives a dignity to the vegetation of that structure which it hitherto has not possessed. It grows freely planted out, or in large tubs, in turfy loam, slightly enriched and well drained. In a warm conservatory or winter-garden, with plenty of space overhead, it ought to be planted out; in a cool house or a small one, it would be better to restrict it to a large pot or tub.

W. R.

Epiphyllum truncatum.—Few plants are better adapted for decorating the stove or warm conservatory during the months of November and December than the different varieties of this Ephyllium. Any new mode, therefore, of displaying their beauties cannot fail to be interesting. A plant of an erect round Cactus, of which I do not know the name, was used here this spring as a stock for in-arching some varieties of *E. truncatum*, and they are just coming now into full flower. This stock was about eight feet in height, and about four feet of it, measuring from the top, was in-arched with the varieties of *E. truncatum*, called *spendens violaceum* and *Ruckerianum*. Next year I intend in-arching some varieties of *truncatum* on the lower portion of the stock, and, judging from the effect of those at present in flower, this plant will, when furnished and in full beauty, make a pyramid of *Epiphyllum* well worth seeing. I have some six varieties of *Epiphyllum truncatum* in-arched on the *Pereckia*; but they are only about three feet in height. Nevertheless, when in flower, they are very beautiful as pyramids.—WILLIAM TILLEY, Welbeck.

Acacia humifusa.—Most of us are familiar with the Acacias, their frequently elegant and not rarely singular leaves, and their form of beautiful, densely-produced flowers. They are widely cultivated in greenhouses and conservatories in this country, but they usually require more nutriment than they can obtain in pots, while, if planted out they generally run up straight to the glass, and become objectionable for that reason, their lower parts getting naked, and the flowers being chiefly presented to the roof. There are, however, some elegant and not over vigorous growers to which this does not so much apply, and which may be trained with good effect over an arch or up a pillar; but generally the different species of this genus are liable to the above objections. It is with much pleasure, then, that we recommend one which, flowering profusely and well, has a directly opposite tendency to those accustomed to wild life in a New Holland Acacia scrub. It is *Acacia humifusa*—which, indeed, grows upward sufficiently to enable us to train it to rafters, pillars, &c., but then begins to throw down long green tresses of fine leaves, and becomes, even when out of flower, a graceful ornament to the conservatory or greenhouse. In spring these long tresses, reminding one of the pendulous shoots of the Weeping Willow, become covered with flowers. The genus *Acacia*, though now considerably reduced, contains upwards of five hundred species, but not one which we should select in preference to this for the purpose herein mentioned. As to culture, there needs little to be said. It, like most of its brethren, will grow in almost any soil. We first saw this plant when visiting the garden at Floors Castle some years ago, but were not fortunate enough to see it in flower. We saw enough, however, to know that *A. humifusa* is about the most valuable plant ever introduced for adding grace to the interior of the conservatory or large cool-house of any kind in which there is room to plant it out.

Rhodanthus Manglesi as a Greenhouse Ornament.—It is when grown in pots for the spring decoration of the conservatory that this charming plant is seen in its finest proportions. For this purpose the seed should be sown the first week in August under glass, and when the young plants are of sufficient size, they should be singled out and planted three or five in a small pot and sheltered until they get established. The compost for them should be equal parts of turfy loam and peat, with a sprinkling of gritty sand for the winter, substituting leaf mould and rotten manure for the peat at the subsequent pottings. The best place for the plants is upon a shelf close to the glass, where, with a free circulation of air, they will be free from damp and cold draughts. Water moderately, and as the plants require it, shift them into larger pots, taking care to stop the side branches when two or three inches long, and remove all flower-buds as fast as they appear until the plants are thoroughly established. With proper attention plants may be had in eleven-inch pots forming half-spheres two feet in diameter, and covered with thousands of flowers. To attain that end the treatment must be liberal; the temperature should be that of the warm greenhouse, with, after Christmas, a warm growing temperature, the heat increasing as the days lengthen. It is, however, essential to make as much headway as possible in the early part of the spring; for, as the light increases, the inclination of the plants to bloom is so great, that it is difficult to produce them of superior size. The plants will enjoy a sprinkling of water daily while in free growth, but as soon as the flowers begin to show colour then the sprinkling must be dispensed with; a moist atmosphere will, however, still be necessary, therefore damp around the pots and the stages and paths in the house. When the plants are fairly established and in free growth, weak manure-water will be of great advantage to them; it may either be prepared from guano or from soot and cow or sheep dung, and it should be used in a perfectly clear state. These plants are subject to mildew in winter, for which sulphur may be used.—B.

Zonale Pelargoniums.—I have raised seedlings of these at the rate of thousands a year for some seasons past, not only in the hope of improving this class of plants, but to multiply the colours. Whatever style of gardening we adopt, it is difficult to conceive any case in which these plants will be given up; for, whether in the form of beds, clumps, or planted singly, there is nothing to equal them in effect, as far as colour is concerned. The artificial crossing of the flowers, and the after-cultivation of the seedlings, has to me been a constant source of pleasure and excitement. As long as bedding-geraniums were nearly all scarlets, there was a sameness about them which prevented many from taking much interest in them; but since we have succeeded in raising so many shades of rose and crimson, I have observed that a marked increase of attention has been directed to them. But it is to their value as winter-blooming greenhouse plants that I would call particular notice. Few have any idea of their excellence in this respect. If a number of plants be well grown in pots all summer, plunged out of doors and not allowed to bloom, and then removed to a greenhouse in autumn, the effect which they will produce will be far greater than that which a lot of chrysanthemums is capable of making, and will be continued three times as long. One great advantage of these plants is, they are never attacked by insects, if we except the green caterpillars of the Angleshades Moth, so that they give little trouble, and do no harm to vines or other plants with which they may be associated. Indeed, I know no tribe of plants capable of producing such an effect as this at so little cost, and for so long a period; and I think good winter-bloomers will soon be in demand, for though all flower well when properly prepared, some bloom much better than others during autumn and winter.—J. B. PEARSON, Chilwell.

Poinsettia pulcherrima.—This old and well-tried favourite still occupies a prominent place in our plant stoves during winter, and if removed when it has fully expanded its large red bracts from the stove to the drawing-room or front hall, where it can enjoy a little warmth, it will be found to be a useful in-door ornament. In such situations, however, watering requires to be carefully attended to. Heavy applications of water are apt to sour the soil and to cause the plants to have a sickly appearance, whereas if proper discretion is exercised they will remain in full beauty for at least three weeks, even at this festive season of the year. By the latter part of January the beauty of the plants will be over, and they may be set out of the way in any house, the minimum temperature of which never falls below 45°. They should, however, be kept dry until the time arrives to cut them down, which will be about the first week in March. Then remove them to a propagating or forcing house. Preserve the wood cut off to work up for next season's supply. In propagating the Poinsettia, most cultivators prefer what may be called the vine-eye system. Select thoroughly ripened wood, and prepare the eyes in the same manner as you would those of the vine; perhaps the best possible time for carrying out this method is about the first week in March; place then the cuttings or eyes thickly over the surface of a pan or a six-inch flower-pot, and set them in the strongest heat at command. When they start into growth, be careful to guard against damp. Another way of increasing the Poinsettia is this:—Take firm young shoots, consisting of three or four joints off the old plants—say, in April—and place them in a strong heat. They will soon strike root, and their after culture will be precisely the same as that for plants struck from eyes. Pot off immediately they are fairly rooted, so as to guard against a check, and as soon as they have filled the pots they are in with roots, shift on into larger pots till the strongest plants are in eight-inch pots and the weaker ones in six-inch ones; and in those they may remain to flower. A moist atmosphere and liberal waterings are required to insure success. Cold draughts are very injurious to this plant, and, therefore, must be avoided; as must also scorching, by timely air giving. Possibly, the best soil for Poinsettias would be equal parts of peat, sand, good turf loam, and leaf mould, well incorporated together. By this treatment, plants with bracts large and brilliant may be obtained. In order to have dwarf specimens, take old plants in March, shake them out, and re-pot them in as small pots as their roots can conveniently be put into, and as soon as they are established, shift them on till you get them into ten-inch pots, or say a very large specimen in a twelve-inch pot, in which it may be allowed to remain to flower. As the shoots advance, tie them out as widely as possible without breaking them. About, say the third week in August, take the shoots and bend them down to within about nine inches of the pot, and secure them there to a stake or the rim of the pot, and in this way form a neat and compact head. When well done the plant assumes a handsome shape; afterwards care must be taken in watering, for if that is not properly attended to the result will be crooked, barren stalks, instead of branches well-furnished with leaves. Everybody knows how difficult it is to keep this plant dwarf and bushy; but the directions just given will secure that desideratum.—H. W.

NOTES AND QUESTIONS ON THE IN-DOOR GARDEN.

Phalzenopsis Lowii.—This is one of the prettiest of the genus. It is found growing on limestone rocks in its native country, where it loses its leaves and takes a period of rest annually. Mr. Page, Park Hill, Streatham, had a plant treated after this fashion, which had all flowers all open on one spike at a time. In natural growth, however, all the year round, which is what it should be potted in rough peat and broken crocks, and should have plenty of water during the growing season. *P. grandiflora*, well established on boards, has been offered for sale in such large quantities lately, and at such low prices, that no stove should be without a dozen or more of it. Suspended in baskets from the roof, few plants are more effective.—W. HOWARD, Bathurst.

Palm Culture.—There is one point—as to the amount of sun or shade palms require—which I do not find mentioned in any books on their culture. I have had some since last spring in a cool fernery, which I am obliged to keep much shaded, as the roof is exposed to the sun. They have hitherto done very well. Query—Will they continue to do so? and are there any palms more particularly suited to a shady situation than others? Mine would never have the development of their fronds fully if placed in a sun-parlor. *Washingtonia* is a palm of great size, and will grow well in a sun-parlor, but it requires a great deal of space, and will not do well in a small room. *Chamaerops humilis* is a palm which will grow well in a sun-parlor, but it requires a great deal of space, and will not do well in a small room. *C. Fortunei*, *C. australis*, *Jubaea spectabilis*, *Rhipis fibrofloriformis*, *Seaforthia elegans*, *Sabal Adamsoni*, and *Corypha australis*.]

Neapolitan Violets at Christmas.—A bunch of violets is always a precious possession—even when days are calm and bright, and the scented air is redundant of the perfume of violets; but when the violet is in the dead of winter! Many years ago, now, in the songs of England we used to have Neapolitan violets at Christmas, and how their odoriferous blossoms mingled with the round red holly berries at our family gatherings in the decline of the fast-fading year. This was how we grew them, and with great success! In May a compost of fibrous loam and leaf mould was made, and with this we constructed a bed on a warm and dry border. Then, selecting the young, vigorous offsets made by the violets, two or three of these were put together, and so many as four or five were placed in this compost, and left for six weeks or eight inches apart; and then they grew, and were allowed to remain until the beginning of August. Then they were placed in pots about six inches in diameter, using a soil composed of two-thirds of leaf mould, and one part maiden loam or a fibrous free character, with some silver sand. We always placed good drainage at the bottom of the pots, and when potted, the plants were placed in some shady position in the open air for about three weeks or a month, and then, when dry, were transferred to a light frame, for winter blooming. Each pot was placed in tan, and a thick lining of loam and short straw was placed round the frame to keep them from frost. In selecting materials for our lining cur was always taken to avoid anything of a heating character, so that dung or other material subject to rapid fermentation was eschewed. When here, our attention was simply directed to keeping the plants protected from cold winds, the ground dry, and consequently free from damp, which is very important in all cases, especially in the case of violets, in which character we obtained plants of Neapolitan violets in pots laden with pleasant flowers at mid-winter! Perhaps our southern locality, almost close to the sea-side, helped us somewhat. We grew these in pots for our pleasant little conservatory and sitting-room that overlooked the silvery waters of the Solent river, that washes part of the south-west coast of Hampshire. Where cut flowers only are required, the plants could be managed equally well planted out in the frame in such a compost as that recommended for pots, care being taken to keep the plants dry during the dull part of the winter.—*Fielder*.

Lachenalia.—These are highly ornamental plants, much too little grown for decorative purposes. They are dwarf, bulbous, South-African plants, and therefore perfectly amenable to greenhouse culture; and few subjects are easier or more useful, as contrasts with other bulbs, than they are when nicely grown. *L. pendula*, tricolor, and aurea are three distinct and beautiful species which, with the more common *L. luteola*, are equally deserving of general cultivation. *Pendula* is of larger size and stature than the others, with plain green leaves and pink flowers, each flower having a central yellow center, and a white fringe along, with spotted leaves, and yellow flowers margined with green and red. *Aurea* is a very scarce sort, which has slightly spotted leaves, purple-spotted scapes, and very beautiful waxy flowers, which are wholly of a rich apricot or golden yellow. Mr. Barron, who grows these plants most successfully as conservatory ornaments, has kindly communicated the following notes on their cultivation:—“When the plants have done flowering, water should be withheld gradually, but not entirely, until the roots are dry, when they may only be kept dry. In August or early in September the bulbs should be taken out of the pots and soil, and assorted, i.e., the larger and the smaller ones each put by themselves. For soil, get some fresh turfy loam and peat, with some sand, and a little manure, mixed up together, and fill this into clean forty-eight-sized pots, well drained—the latter a very important point; place from five to eight flower-bulbs in each pot, just above the common level of the soil, and plant them in the frame, until they commence to grow. In October they must be placed in some cool pit or house near to the glass, as they love abundance of light and air. The temperature must just be sufficient to exclude frost, but they dislike heat, which makes the leaves draw up weakly and lankly. They require careful watering during winter; otherwise at that season they are liable to die off. When coming into flower, however, they need abundance of water, and sometimes a slight benefit to help the flowers to expand. The different sorts cannot be treated alike; *aurea*, which has been nearly lost to our gardens, harbors a strong and powerful habit of refusing to grow at all some seasons. My stock of it rested for two seasons, remaining quite dormant, and this season they have only started into growth after having the assistance of a strong stove temperature.” Mr. Stevens, gardener to G. Simpson, Esq., Way Park, Reigate, exhibited a South Kensington, last spring, a charming *L. luteola* bulb of L. 1, which he thinks has been good enough to send the following memorandum on his method of growing these wonderful specimens:—“I start them the first week in September, and put them in the coldest house I have got. When they have started into growth, I give them a little manure-water made of soot and cow-dung, which I find they delight in. I plant them in the strongest loam I can find, mixing a little cow-dung with it, and I find them to do well in it. I have at the present time five baskets of them, which I think will be better than the one I brought up to London last spring.”—*Florist and Pomologist*.

THE ARBORETUM.

THE BIG TREE—SEQUOIA (WELLINGTONIA)
GIGANTEA.

So many imperfect and incorrect accounts of this tree have appeared in journals at different times, that the following, by Professor Whitney, the State Geologist of California, in "The Yosemite Book," will, doubtless, be acceptable to all tree lovers. Very little that is trustworthy has been published either in this country or America on this subject:

According to Mr. Hutchings's statement, the Calaveras Grove of Big Trees was the first one discovered by white men, and the date was the spring of 1852. The person who first stumbled on these vegetable monsters was Mr. A. T. Dowd, a hunter employed by the Union Water Company to supply the men in their employ with fresh meat, while digging a canal to bring water down to Murphy's. According to the accounts, the discoverer found that his story gained so little credence among the workmen, that he was obliged to resort to a ruse to get them to the spot where the trees were. The wonderful tale of the Big Trees found its way into the papers, and appears to have been first published in the *Sonora Herald*, the nearest periodical to the locality. The account was republished, among other papers, in the *Echo du Pacific* of San Francisco, then copied into the London *Athenaeum* of July 23, 1853 (p. 892), which is believed to be the first notice published in Europe, and from there again into the *Gardeners' Chronicle* of London, where it appeared July 30, 1853 (p. 488). In the last-named journal, for December 24th, page 819, Dr. Lindley published the first scientific description of the Big Tree. Overlooking its close affinity with the already-described redwood, he regarded it as the type of a new genus, which he called Wellingtonia, adding the specific name of gigantea. His specimens were received from Mr. William Lobb, through Messrs. Veitch & Sons, well-known nurserymen. The tree had been previously brought to the notice of scientific men in San Francisco, and specimens had been sent to Dr. Torrey in New York considerably earlier than to Dr. Lindley, but the specimens were lost in transmission; and, no description having been published in San Francisco, although Drs. Kellogg and Behr had brought it to the notice of the California Academy early that year as a new species, the honour and opportunity of naming it was lost to American botanists. The closely allied species of the same genus, the *Sequoia sempervirens*, the redwood, had been named and described by Endlicher in 1847, and was well known to botanists all over the world in 1852.

At the meeting of the "Société Botanique de France," held June 28, 1854, the eminent botanist Decaisne presented specimens of the two species, the Big Tree and the redwood, with those of other Californian conifers recently received from the Consular Agent of France at San Francisco. At this meeting M. Decaisne gave his reasons, at some length, for considering the redwood, and the more recently discovered "Big Tree" to belong to the same genus, *Sequoia*, and in accordance with the rules of botanical nomenclature, called the new species *Sequoia gigantea*. The report of these proceedings is to be found in the *Bulletin de la Société Botanique de France*, Vol. I., p. 70, which was issued in July (probably) of 1854.

In the meantime, specimens had been received by Dr. Torrey at New York, and in September of the same year, 1854, Professor Gray, of Cambridge, published, in the *American Journal of Science*, appended to a notice of the age of the redwood, a statement, on his own authority, that a comparison of the cones of that tree and those of the so-called Wellingtonia of Lindley, did not bring to view any differences adequate to the establishment of a new genus. To this Professor Gray adds:—"The so-called Wellingtonia will hereafter bear the name imposed by Dr. Torrey, namely, that of *Sequoia gigantea*." It does not appear, however, on examination, that Dr. Torrey had himself published any description of the Big Tree, or of the fact that he considered it generically identical with the redwood, and priority seems to have been secured by Decaisne, so that the name must stand as *Sequoia gigantea* Decaisne.

No other plant ever attracted so much attention, or attained such a celebrity within so short a period. The references to it in scientific works and journals already number between one and two hundred, and it has been the theme of innumerable articles in popular periodicals and books of travel, in various languages; probably there is hardly a newspaper in Christendom that has not published some item on the subject. Seeds were first sent to Europe and the Eastern States in 1853, and since that time immense numbers have found their way to market. They germinate readily, and it is probable that hundreds of thousands of the trees (millions, it is said) are growing in different parts of the world from seeds planted.

The genus was named in honour of Sequoia, or Sequoyah, a Cherokee Indian of mixed blood, better known by his English name of George Guess, who is supposed to have been born about 1770, and who lived in Will's Valley, in the extreme north-eastern corner of Alabama, among the Cherokees. He became known to the world by his invention of an alphabet and written language for his tribe. This alphabet, which was constructed with wonderful ingenuity, consisted of eighty-six characters, each representing a syllable; and it had already come into use to a considerable extent before the whites had heard anything of it. After a time the missionaries took up Sequoyah's idea, and had types cast and a printing-press supplied to the Cherokee nation, and a newspaper was started in 1828, partly in this character. Driven with the rest of his tribe beyond the Mississippi, he died in New Mexico in 1843. His remarkable alphabet is still in use, although destined to pass away with his nation, but not into oblivion; for his name, attached to one of the grandest and most impressive productions of the vegetable kingdom, will for ever keep his memory green.

The Big Tree occurs exclusively in "groves," or scattered over limited areas, never forming groups by themselves, but always disseminated among a much larger number of trees of other kinds. The groves of the Big Trees are limited in latitude between 36° and 38° 15' nearly, at least so far as we now know. The Calaveras Grove is the most northerly, and one on the south fork of the Tule is the farthest south of any yet known to us. They are also quite limited in vertical range, since they nowhere descend much below 5,000 or rise above 7,000 feet. They follow the other trees of California, in this respect, that they occur lower down on the Sierra as we go northwards; the most northerly grove, that of Calaveras, is the lowest in elevation above the sea-level.

There are eight distinct patches or groves of the Big Trees—or nine, if we should consider the Mariposa trees as belonging to two different groups, which is hardly necessary, inasmuch as there is only a ridge half a mile in width separating the upper grove from the lower. The eight groves are, in geographical order from north to south: first, the Calaveras; second, the Stanislaus; third, Crane Flat; fourth, Mariposa; fifth, Fresno; sixth, King's and Kaweah rivers; seventh, North Fork Tule river; eighth, South Fork Tule river.

The Calaveras Grove is situated in the county of that name, about sixteen miles from Murphy's Camp, and near the Stanislaus river. It is on, or near, the road crossing the Sierra by the Silver Mountain Pass. This being the first grove of the Big Trees discovered, and the most accessible, it has come more into notice, and been much more visited than any of the others; indeed, this and the Mariposa Grove are the only ones which have become a resort for travellers. The Calaveras Grove has also the great advantage over the others, that a good hotel is kept there, and that it is accessible on wheels, all the others being at a greater or less distance from any road.

This grove occupies a belt 3,200 feet long by 700 feet broad, extending in a north-west and south-east direction, in a depression between two slopes, through which meanders a small brook which dries up in the summer. There are between 90 and 100 trees of large size in the grove, and a considerable number of small ones, chiefly on the outskirts. Several have fallen since the grove was discovered; one has been cut down; and one has had the bark stripped from it up to the height of 116 feet above the ground. The bark thus removed was exhibited in different places, and finally found a resting-place in the Sydenham Crystal Palace, where it was unfortunately burned in the fire which consumed a part of that building a few years ago. The two trees thus described were perhaps the finest in the grove; the tallest now standing is the one called the "Keystone State"; the largest and finest is known as the "Empire State." The height of this grove above the sea-level is 4,759 feet.

The exact measurement of the diameter and the ascertaining of the age of one of the largest trees in this grove was made possible by cutting it down. This was done soon after the grove was discovered, and is said to have occupied five men during twenty-two days. The felling was done by boring through the tree with pump-axes; it was no small affair to persuade the trunk to fall, even after it had been completely severed from its connection with the base. It was done, however, by driving in wedges on one side, until the ponderous mass was inclined sufficiently, which was not effected until after three days of labour.

The stump of this tree was squared off smoothly at six feet above the ground, and the bark being removed, a pavilion was built over it, forming a capacious room, the exact dimensions of the stump inside of the bark being,

Across its longest diameter, south of centre, 13 feet 9 inches.
" " " " north of centre, 10 " 4 "

Total longest diameter 21 feet 1 $\frac{1}{2}$ inches.

The shorter diameter, or that east and west, was 23 feet, divided

[DEC. 16, 1871.]

exactly even on each side of the centre. The thickness of the bark, averaging 18 inches probably, would add three feet to the diameter of the tree, making 26 feet in all. After this tree had been cut down, it was again cut through about 30 feet from the first cut. At the upper end of this section of the trunk, or about 40 feet from the ground, as the tree originally stood, we carefully counted the rings of annual growth, measuring at the same time the width of each set of one hundred, beginning at the exterior; the result was as follows:—

First hundred	3.0 inches.
Second	3.7 "
Third	4.1 "
Fourth	3.9 "
Fifth	4.1 "
Sixth	4.1 "
Seventh	4.6 "
Eighth	5.6 "
Ninth	7.3 "
Tenth	7.9 "
Eleventh	10.1 "
Twelfth	13.0 "
55 years	9.4 "

1,255 years. 80.8 inches.

There was a small cavity in the centre of the tree which prevented an accurate fixing of its age; but making due allowance for that, and for the time required to grow to the height at which the count was made, it will be safe to say that this particular tree, which was probably about as large as any now standing in the grove, was, in round numbers, 1,300 years old.

The Calaveras Grove contains, as will be seen in the table, four trees over 300 feet high, the highest one measured in the Mariposa Grove being 272. The published statements of the heights of those trees are considerably exaggerated, as will be noticed; but our measurements can be relied on as being correct.* The Keystone State has the honour of standing at the head, with 325 feet as its elevation, and this is the tallest tree yet measured on this continent, so far as our information goes. When we observe how regularly and gradually the trees diminish in size, from the highest down, it will be evident that the stories told, of trees having once stood in this grove over 400 feet in height, are not entitled to credence. It is not at all likely that any one tree should have overtopped all the others by 75 feet or more. The same condition of general average elevation, and absence of trees very much taller than any of the rest in the grove, will be noticed among the trees on the Mariposa Grant, where, however, there is no one as high as 300 feet.

The Mariposa Grove is situated about sixteen miles directly south of the Lower Hotel in the Yosemite Valley, and between three and four miles south-east of Clark's Ranch, and at an elevation of about 1,500 feet above the last-named place, or of 5,500 feet above the sea-level. It lies in a little valley, occupying a depression on the back of a ridge, which runs along in an easterly direction between Big Creek and the South Merced. One of the branches of the creek begins in the grove.

The grant made by Congress is two miles square, and embraces, in reality, two distinct, or nearly distinct, groves; that is to say, two collections of Big Trees, between which there is an intervening space without any. The Upper Grove is a pretty compact body, containing, on an area of 3,700 by 2,300 feet in dimensions, just 365 trees of the Sequoia gigantea, of a diameter of one foot and over, besides a great number of small ones. The lower grove, which is smaller in size and more scattered, lies in a south-westerly direction from the other, some trees growing quite high up in the gulches on the south side of the ridge which separates the two groves.

The trail approaches the Upper Grove from the west side, and passes through and around it, in such a manner as to take the visitor very near to almost all the largest trees; to accomplish this, it ascends one branch of the creek and then crosses over and descends the other, showing that the size of the trees depends somewhat on their position in regard to water. Still, there are several very large ones on the side hill south of the creek, quite high above the water.

Several of the trees in this grove have been named, some of them, indeed, half a dozen times; there are no names, however, which seem to have become current, as is the case in the Calaveras Grove. A plan has been drawn for the commissioners, however, showing each tree, with its exact position and size, a number being attached to each. The circumference of every tree in the grove was also

carefully measured, and the height of such as could be conveniently got at for this purpose.

There are several trees in this grove considerably larger than any that are to be found in the Calaveras, and their average size is greater. The average height of the Mariposa trees, however, is less than that of the Calaveras; and the highest of the former, 272 feet, is 53 feet less than the tallest one of the latter. There is a burned stump on the north side of the grove, nearly all gone, but indicating a tree of a size perhaps a little greater than any now existing here. The beauty of the Mariposa Grove has been sadly marred by the ravages of fire, which has evidently swept through it again and again, almost ruining many of the finest trees. Still, the general appearance of the grove is extremely grand and imposing. There are about 125 trees over 40 feet in circumference.

The principal trees associated with the Big Trees in this grove are, the pitch and sugar pines, the Douglas spruce, the white fir (*Picea grandis*), and the bastard cedar (*Libocedrus decurrens*); the latter so much resembles the Big Tree in the general appearance of its trunk and bark, that there was no person in our party who could certainly distinguish the two species at a little distance.

There are but very few of the young Big Trees growing within the grove, where probably they have been destroyed by fire; around the base of several of the large trees, on the outskirts of the grove, there are small plantations of young Sequoias, of all sizes, up to six or eight inches in diameter, but only a few as large as this. Those trees which are about ten feet in diameter and entirely uninjured by fire, in the full symmetry of a vigorous growth of say 500 years, are, although not as stately as the older giants of the forest, still exceedingly beautiful and impressive.

The meadows near the Big Trees abound in gay, blooming flowers. Mr. Bolander enumerates, as the most conspicuous: *Rudbeckia californica*—Gray; *Aconitum nasutum*—Fischer; *Anisognathus bolanderi*—Gray; *Boykinia occidentalis*—T. and G.; *Sidalcea malvaefolia*—Gray; *Myrica Gale*—L.; *Hulsea brevifolia*—Gray; *Epilobium angustifolium*; *Vaccinium californicum*. A species of lupine is very abundant, and this, with the Rudbeckia, gives the main colouring to the meadows, which also abound with numerous carices.

The southern division of the Mariposa Grove, or Lower Grove, as it is usually called, is said to contain about half as many trees as the one just described. They are much scattered among other trees, and do not, therefore, present as imposing an appearance as those in the other grove, where quite a large number can often be seen from one point. The largest tree in the Lower Grove is the one known as the "Grizzly Giant," which is 93 feet 7 inches in circumference at the ground, and 64 feet 3 inches at 11 feet above. Its two diameters at the base, as near as we could measure, were 30 and 31 feet. The calculated diameter, at 11 feet above the ground, is 20 feet nearly. The tree is very much injured and decreased in size by burning, for which no allowance has been made in the above measurements. Some of the branches of this tree are fully six feet in diameter, or as large as the trunks of the largest oaks of the Connecticut Valley, of which Dr. Holmes has so pleasantly discoursed in the *Atlantic Monthly*. This tree, however, has long since passed its prime, and has the bated and war-worn appearance conveyed by its name.

No other grove of Big Trees has been discovered to the south-east of this, along the slope of the Sierra, until we reach a point more than fifty miles distant from the Fresno Grove. Here, between the King's and Kaweah rivers, is by far the most extensive collection of trees of this species which has yet been discovered in the State. This belt of trees, for grove it can hardly be called, occurs about thirty miles north-north-east of Visalia, on the tributaries of the King's and Kaweah rivers, and on the divide between. They are scattered over the slopes and on the valleys, but are larger in the depressions, where the soil is more moist. Along the trail which runs from Visalia to the Big Meadows, the belt is four or five miles wide, and it extends over a vertical range of about 2,500 feet; its total length is as much as eight or ten miles, and may be more. The trees are not collected together in groves, but are scattered through the forests, and associated with the other species usually occurring at this altitude in the Sierra; they are most abundant at from 6,000 to 7,000 feet elevation above the sea-level. Their number is great; probably thousands might be counted. Their size, however, is not great, the average being from ten to twelve feet in diameter, and but few exceeding 20 feet; but smaller trees are very numerous. One tree, which had been cut, had a diameter of eight feet, exclusive of the bark, and was 377 years old. The largest one seen was near Thomas's Mill; this had a circumference of 106 feet near the ground, no allowance being made for a portion which was burned away at the base. When entire the tree may have been ten or twelve feet more in circumference. At about twelve feet from the ground, the circumference was 75 feet. Its height was 276 feet. The top was dead,

* Several trees were measured twice, and the results, in every case, proved to be closely coincident.

OLD SPECIMEN OF SEQUOIA (WELLINGTONIA) GIGANTEA, 93 FEET 7 INCHES IN CIRCUMFERENCE, AND 299 FEET HIGH.

however, and, although the tree was symmetrical and in good growth, it had passed its prime.

Another tree, which had fallen, and had been burned hollow, was so large that three horsemen could ride abreast into the cavity for a distance of 30 feet, its height and width being about 11 feet. At a distance of 70 feet the diameter of the cavity was still as much as eight feet. The base of this tree could not be easily measured; but the trunk was burned through at 120 feet from the ground, and at that point had a diameter (exclusive of the bark) of 13 feet 2 inches; and, at 169 feet from its base, the tree was nine feet in diameter. The Indians stated that a still larger tree existed to the north of King's River. This tree should be looked up and carefully measured; unfortunately, it was not in the power of our party to do this.

All through these forests there are numerous young Big Trees, of all sizes, from the seedling upwards; and at Thomas's Mill they are cut up for lumber, in a manner quite at variance with the oft-repeated story of the exceptional character of the species. Prostrate trunks of old trees are also numerous; some of them must have lain for ages, as they were nearly gone, while the wood is very durable.

Not one of the Big Trees has ever been found south of the grove on the south fork of the Tul. The region has not, however, been so thoroughly explored that it would be safe to say that none exist there. Judging from the extent of the area over which this species is scattered, between King's and Kaweah rivers, it would seem that here was its most congenial habitat, and it may eventually be found that this tree forms pretty nearly a continuous belt for some fifty or sixty miles.

From what has been here stated the reader will easily gather that the Big Tree is not that wonderfully exceptional thing which popular writers have almost always described it as being. It is not so restricted in its range as some other species of the Coniferae in California; it occurs in great abundance, of all ages and sizes, and there is no reason to suppose that it is now dying out, or that it belongs to a past geological era, any more than the redwood. The age of the Big Trees is not so great as that assigned, by the highest authorities, to some of the English yews. Neither is its height as great, by far, as that of an Australian species, the *Eucalyptus amygdalina*, many of which have, on the authority of Dr. Müller, the eminent Government botanist, been found to measure over 400 feet. One, indeed, reaches the enormous elevation of 480 feet, thus overtopping the tallest Sequoia by 155 feet. There are also trees which exceed the Big Tree in diameter, as, for instance, the Baobab (*Adansonia digitata*); but this species is always comparatively low, not exceeding 60 or 70 feet in height, and much swollen at the base.

On the whole, it may be stated, that there is no known tree which approaches the Sequoia in grandeur, thickness and height being both taken into consideration, unless it be the Eucalyptus. The largest Australian tree yet reported is said to be 81 feet in circumference at four feet from the ground; this is nearly, but not quite, as large as some of the largest of the Big Trees of California.

THE ARBORETUM FOR DECEMBER.

All land in a natural state intended to be planted should be drained, trenched, or ploughed, and subsoiled according to circumstances, a description of work, indeed, in which the steam-plough might in many instances be profitably employed. Nevertheless, however well ground for planting may be prepared at first, it will require to be kept clear of weeds and bushes for some three or four years afterwards, otherwise the tree-roots will be deprived of their proper amount of food by thickets of weeds and underwood. When the trees shall have attained a certain size they will take care of themselves, keeping all such intruders in check under their shade. Where plantations to be made are of considerable extent, let the trees of which they are to consist be put in, so as to stand in rows every way, an arrangement of much importance, as it admits of horse-boeing being carried on in all directions, and thus may be speedily and readily cleaned, provided the work is taken in hand before weeds or other undergrowth have arrived at a size to offer any serious obstruction to its efficient performance. Where the ground to be planted is steep and awkward to work, the best plan is to plant thickly such trees as Scotch firs, larch, and Spanish chestnut; and in low, swampy spots, ash and willow, all of which will soon attain a size sufficient for poles, first for hops and then for fencing. Both hilly and flat districts, I need scarcely say, are much improved by trees, which, as far as landscape scenery is concerned, should consist of as much variety as possible, and, after having been planted a few years, they will be found to yield a profitable return. Larch, Scotch and spruce firs, birch, beech, ash, and oak are what have been chiefly planted in days gone by, and of these some fine plantations may still be found. Now, however, we have so much variety from which to select, both in the way of pinuses and other

kinds of trees, that old-fashioned woods do very little more than furnish materials for nurses or shelter. *Abies Douglasii* and *A. taxifolia* are both wonderfully free rapid-growing trees, consisting of wood, tough and strong, and full of turpentine. *Ponderosa* is also a valuable Pine, and so is *P. Menziesii*, where it makes a good start; but it does not succeed so well in some parts of the country as in others. Various other pines and firs might also be dotted about in new plantations with advantage, taking care to place them in aspects which they will thrive best, and to give them sufficient room in which to fully develop themselves. The variegated and common sycamore, the wood of which is largely used for household furniture, should also be freely planted, and the wild cherry, so beautiful in spring and autumn, should likewise have a place in all new plantations, its wood being much sought after by cabinet-makers. All these and many others would be found to add wealth and beauty to a country, if plantations of them were made, as they should be, in a methodic and systematic manner.

JAMES BARNES.

THE HOUSEHOLD.

TINNED FRUITS AND VEGETABLES.

In connection with this subject, to which we have several times alluded in this department of THE GARDEN, we beg to call attention to an article in the *Standard*, of Monday, the 11th inst., in which the whole subject of preserved fruits, vegetables, and meats, is discussed with considerable knowledge and ability. The importance of the subject can scarcely be appreciated by persons who know nothing of what has been done in this way in France, and more especially in America, during the past few years, and therefore we have much pleasure in transferring to our pages that part which is devoted to fruits and vegetables:—

A large variety of vegetables scarcely lose any of their flavour through the process of preserving, such as beans, celery, spinach, carrots, asparagus, mushrooms, tomatoes, and artichokes; and a mixture of vegetables cut into pretty designs, under the name of *médaillons*, may also be mentioned as most useful for soups, entrées, and stews. Peas are preserved in excellent condition without any use of copper to give them colour—this being obtained, we believe, by the simple juice of spinach. They are of three qualities, or rather sizes, which are obtained by passing them as they are shelled through sieves of different meshes, the smallest, and consequently youngest and tenderest, peas passing through all to the bottom, the largest remaining in the top sieve. These are, of course, the most delicate in flavour, and obtain the highest price, as only fifteen bushels of them are obtained on an average from fifty shelled into the sieves. The art of preserving these peas has now reached such a high point of excellence that it is almost impossible to distinguish them from those fresh gathered; and it is well known in the trade that early in the season they, under the name and at the cost of fresh peas, are consumed in very large quantities at the first-class hotels and restaurants in London, Paris, and other Continental cities, as well as at the tables of private houses. The trade in this one article has so greatly increased of late that, as we have been informed, from twenty thousand tins, the sale at one establishment alone has risen to five hundred thousand annually in the last four years. A tin containing one pint of the best quality, the *Petits-Pois à l'Anglaise*, is retailed at about 1s. 4d.; the larger kind, the *Gros Pois*, at about 1d. Dried, mixed vegetables, in small shreds, have not received from the English public the attention which they deserve from their excellence, cheapness, and convenient form. M. Masson, of Paris, was, we believe, the first to adopt this method of preserving at the time of the Crimean war, when large compressed cakes were sent out to the French troops. After the war large quantities of these were sent to England, but, being of a somewhat coarse nature, were not much appreciated—meeting, however, with a much more favourable reception some hundreds of miles in the interior of Australia, whither some found their way. A great improvement has, however, been made on them. It may be stated that for a little over a halfpenny, a quart of soup may be flavoured, and the vegetables when eaten with it are as good as those used fresh. It is greatly to be wondered at that they are not used in every household, even those of the poor, as when simply boiled they make an excellent dish of vegetables, and comparatively cheap, in consequence of there being no waste, as in the case of fresh vegetables. They are incorporated with meat and essence of beef in Whitehead's "Gargantua" solid squares, at less than 1s. 6d., one of which, boiled in three pints of water, makes a deliciously-flavoured pot-pourri of 4lbs. weight of nutritious food.

The American tomatoes, called by our cousins "love apples," after the German "leibapfel," seem to be making their way in this

country. They are most extensively used in the States, a dinner-table being seldom without them, and they are to be found in tins in every grocer's shop, and though somewhat inferior in flavour to those produced in the south of France, their cheapness will recommend them here. Green corn—that is, Indian maize—cooked in its "milky" state before it is ripe, is a still more indispensable article on American dinner-tables. It is now sent here, as preserved for home use in winter, in tins, with the grains stripped from the cob. Warmed in milk, with the addition of a little butter, it is eaten as a vegetable, and though requiring somewhat of an acquired taste, should, from its cheapness, find a large number of consumers. Green Lima beans have also been sent from America to this country, and can be retailed in one pound tins at one shilling; but we are not in a position to speak of their quality. With the exception of desiccated potatoes, we believe that few vegetables are preserved in England as articles of luxury; they are, however, simply boiled and preserved in tins, more for shipping and for exportation than for home consumption, and though when re-warmed hardly distinguishable from fresh-cooked ones, there is no saving in their cost; but it would be very convenient to have such articles in stock for daily use.

Various fruits are preserved in tins in this country; but the best as conserves for dessert have hitherto been considered those imported from France. M. Ponçon, who is justly considered one of the best fruit-preservers in the world, is employed by several firms to preserve apricots, peaches, and other fruits for them; and for this purpose he goes to Lisbon every year. The fruit he sends home cannot be exceeded in quality; but those prepared by Rodrigues, of Lisbon, leave nothing to be desired. It seems, however, more than probable that the American fruit, introduced comparatively lately, will command a large consumption, not only from its cheapness, but its excellence. Tins containing apricots and pine-apples in syrup, weighing from a pound and a half to three-quarters, are retailed at 1s. 6d. each, and peaches at 1s.; and the only fault we can find with them is that they are called two-pound tins, thus perpetuating and even renewing, the wretched difference between reputed and actual or standard weights and measures, from which we hope eventually to be delivered. Of the preserved pine-apple we can speak with unqualified praise, its exquisite flavour being rather improved than deteriorated by the preserving process. When these fruits become more used in England, we shall probably receive them at a still cheaper rate; the prime cost of many of them in America, being hardly appreciable, from their great abundance. Peaches we are aware are in that country used partly as food for pigs; and in a description we lately read of a 40-acre orchard in California, near Yuba City, it was stated that there were 25,000 one-year-old peach trees and 16,000 of plums in the "nursery," while in the bearing part of the orchard there were 600 two-year-old peach trees, many of which bore this season 150 lbs. of fruit each, and 2,200 apricot trees. The peach crop in Delaware, this season has produced about 4,000,000 baskets, at the value of about 1,500,000 dollars. Apples also are a mere drug in the American market, and might, we think, be introduced here in the form of pulp or jam, unless English apples could be so tinned in the districts in which they are produced and sold at a less price than pudding apples are now retailed in our towns. This is by no means an unimportant subject for consideration, as apples for cooking purposes are a most wholesome fruit, and it would be a great boon if the poor in populous places could obtain them at a cheaper rate. The present price for common cooking apples at reputedly cheap shops is about a penny, and even more per pound, which, when peeled and cooked, does not provide a sufficient portion for one person. We are aware that this is an exceptionally dear year, but we think that the present method of retailing them at shops till late in the season involves a great waste and consequent increase of price, which might to a great extent be avoided if they were tinned when ripe at or near the place of their production. They are now largely used in the manufacture of cheap jams of various kinds; we see no reason why they should not be used simply by themselves. The American farmers employ their families in the evening in peeling and cutting up apples into what children call "pigs," and threading them on thin string to dry; and in this form many are imported into England for shipping purposes. They could be retailed at about 7d. per pound, or even less, in London, if there were a demand for them, and their use would be well worth a trial, as we find that after soaking for twenty-four hours in water about half a pound will make a pudding for five persons, which is at a cheaper rate than it can be made even in ordinary seasons from apples bought from retail shops in our towns. Our concluding remarks on this part of our subject must be in favour of the 2lb. tins of Chaumont pears put up at a price which would be about 2s. 3d. retail; in our opinion they are a conserve exceeding in delicacy even the best brands of apricots, peaches, and pine-apples.

In the above remarks we have mentioned various articles of great excellence; but in such matters the public should, after careful

experiment, judge for itself, following as closely as possible the "directions for use," and remembering, above all things, that most of these goods have already been cooked and even overcooked, and therefore only require to be rewarmed, but not recooked, when eaten hot. What we chiefly complain of, is the amount of prejudice and the want of enterprise in all matters of new forms of food offered to us. The wise king prayed, "Feed me with food convenient for me;" but we are apt, as in the case of Australian meat and preserved milk, to shut our eyes to its convenience and various advantages because it may be new to us. We are now allowing various articles, including cheap luxuries in tin cases, to be used almost exclusively on our passenger ships, and exported to foreign countries, or lie unused in warehouses, while their fitting place should be in a store-room in every household, to be used as occasion might require. But, resist it as we will, the ages, as fabled by the poets, of iron, brass, silver, and gold have passed, and the age of tin has come; and we cannot resist the world-wide tendency of preserving and tinning the various products of the earth at or near the spot where they are produced; and then of transmitting and disseminating them by the increased and increasing means of transit to the various countries of the globe which require them. Waste is thus prevented, adulteration well nigh rendered impossible, and prices lowered and equalised for articles both of necessity and luxury,

"Accuse not Nature; she hath done her part:

Do thou but thine."

We shall best do it by laying aside prejudice, and by the use and interchange of the manifold riches of the earth, which modern science and enterprise have rendered more convenient for our adoption; and thus realizing, in the matter of food at least, a cosmopolitan communism.

GARDEN DESIGN.

THE KITCHEN GARDEN AT BERRY HILL.

If asked to name a few places in which true taste in garden design was evinced, we should certainly not omit the name of Berry Hill. Seldom have we seen so neatly-arranged a kitchen and forcing department, hardly ever such charming planting as that around the lake. However, we are at present only concerned with the kitchen and forcing departments, which were always seen in such excellent condition under the management of Mr. Rogers, now the superintendent of Battersea Park. The garden is far from being large, but it is most complete in the variety and excellence of its glass structures. A noticeable feature is the way the garden is placed lengthwise near the road. By this means the breadth of park or pleasure-ground is not in the least interfered with. The judicious way in which this is arranged cannot, however, be appreciated by seeing the plan of the kitchen-garden only. Crops were confined on the pieces marked as such, to celery, carrots, parsnips, and beet, and other subjects that occupy the ground for one year only. One feature not shown on the annexed plan deserves notice. It is its flower-beds on the strip of grass running up each side of the central walk. These were cut off on each side by a low hedge of roses. A bold and most graceful entrance to the kitchen-garden consists of two specimens of the weeping beech trained in the form of a large arch. At present Berry Hill is not occupied, and on that account is deprived of much of its gardening interest, but the stamp of thoughtful and graceful design is not one that even neglect, which soon plays such havoc with cultivated or "dressed" ground, can efface. Berry Hill was, we believe, begun by Mr. Kemp, but was completed by Mr. Marnock, to whose true taste we owe its most charming features.

Gates.—Fancy, if you can, a rural home without its gateway—lying all abroad upon a common! The great charm of privacy is gone utterly; and no device of shrubbery, or hedge, can make good the loss of some little wicket which will invite approach and be a barrier against too easy familiarity. The creak of the gate-hinge is a welcome to the visitor, and as he goes out, the latch-clicks an adieu. But there are all sorts of gates, as there are all sorts of welcomes; there is, first, your inhospitable one, made mostly, I should say, of matched boards, with a row of pleasant iron spikes running along its top, and no architectural decorations of pilaster or panel can possibly remove its thoroughly inhospitable aspect. It belongs to stable-courts or gaol-yards, but never to a home or to a garden. Again, there are your ceremonious gates, of open-work indeed, but ponderous and most times scrupulously closed; the very opening of them is a fatiguing ceremonial, and there is nothing like a lively welcome in the dull clang of their ponderous latches. Next, there is your simple, unpretending rural gate, giving promise of unpretending rural beauties—homely in all its aspect, and giving fore-taste of the best of homeliness within. And I make a wide distinction

PLAN OF THE KITCHEN-GARDEN AND GLASS DEPARTMENT AT BERRY HILL, TAPLOW, BERKS.

here between the simple rurality at which I have hinted, and that grotesqueness which is compassed by scores of crooked limbs and knots wrought into labyrinthine patterns, which puzzle the eye, more than they please. All crooked things are not necessarily charming, and the better kind of homeliness is measured by something besides mere roughness. Lastly, there is your hospitable gate, with its little rooflet stretched over it, as if to invite the stranger loiterer to partake at his will of that much of the hospitalities of the home.—*D. G. Mitchell.*

MOVABLE GARDEN FOUNTAINS.

MANY a shady garden nook might be very advantageously lighted up with the sparkle, movement, and murmur of a pretty fountain. For the want of some culminating point of interest, such a spot is often passed by without notice, though possessing many attractions which could not fail to be appreciated if a passing attention could be secured to them, and the eye given time to examine them. The gushing sound of a fountain, as its waters are shot upwards, or the low music of their falling plash, like the soft prattle of subdued whisperings, combined with the visionary

Movable Fountain Hose.

water may be allowed to waste itself, with useful results, over the surrounding turf, and sink to the thirsty roots of the neighbouring shrubs.

The movable fountain is a Transatlantic suggestion, and is much used in the parks and gardens near the great American cities, both as a pleasing object and as a means for thoroughly saturating expanses of turf in very dry seasons, being moved from place to place till the desired purpose is effected.

H. N. H.

The Slaughter of the Evergreens.—What a pity it is we do not contrive some less expensive and more attractive way of destroying the thousands of evergreens planted about London every year, than that of planting them and allowing them to blacken and perish before our eyes from the effects of our smoke-pested air! There perish annually as many beautiful young evergreen shrubs and trees in and near London from smoke as would suffice to plant a whole country. We know no greater evidence of obtuseness of mind than is shown by this persistent wasting of precious time and precious energy and destruction of healthful and beautiful young evergreen trees and shrubs. It cannot be too widely known to every town-planter that so long as we are satisfied to live in a sea of the refuse of our fire-places, so long shall we find it impossible to have in cities healthy specimens of vegetation that retain their foliage in winter.

THE GARDEN IN THE HOUSE.

TALL VASES UPON DINNER-TABLES.

As most of the remarks which I now propose to offer will have reference to the accompanying illustrations, it will make those remarks more readily intelligible if I prefac them with a somewhat detailed explanation of the illustrations.

Each figure represents a table six feet six inches long, by four feet six inches wide. It is a common size in small houses, and by the addition of extra leaves can be made to accommodate sixteen diners. In the middle of each figure will be observed a rectangular space, ruled across with thick lines in various directions; this space represents that portion of the table which is more than fifteen inches from the edge. Within this space are placed the several kinds of ornaments designated (with more or less propriety) "dinner-table decorations," the marginal fifteen inches being reserved for more necessary articles.

Around each table are placed dots indicating where the seats of the diners could be placed if eight persons were to

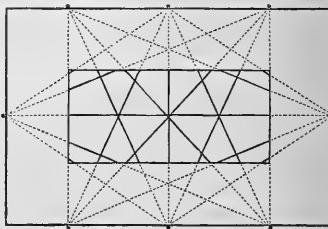

Fig. A.

form the party. In Fig. A there is one seat at each end of the table, and there are three on either side. In Fig. B there are two seats at each end, and two on each side of the table. As far as the convenience of those dining is concerned, there is no advantage in either arrangement over the other, for every one has an allowance of at least two feet for elbow-room in each case.

It will further be noticed that lines have been ruled from each seat to every other seat at the table (except to the seats on each side of it). These lines indicate the lines of sight between all the diners, and it is scarcely necessary to observe

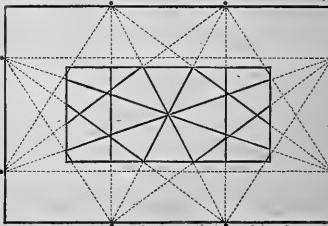

Fig. B.

than any high ornament standing where one or more of these lines cross the table must be an annoyance to two or more of the party.

If I have succeeded in making these explanations intelligible, it will perhaps not be thought surprising that the fashion of the present day is to use nothing on the table that is more than fifteen inches high, because any decoration above that height, and less than twenty inches high, is liable to intercept the view, and thus interfere with the sociability of the dinner. Fashion, we all know, is liable to run into extremes, hence the introduction of zinc and glass trays and dishes little more than an inch high in order that flowers may be arranged as flat as possible on the dining-table. Into these we often see fragments of flowers stuck, without regard to anything but

colour, and without similitude to anything in nature. Dreadful to relate, these miserable imitations of tessellated pavements and French shawls have actually had prizes awarded to them on many occasions at exhibitions! Let us hope that in future judges will be more considerate.

While expressing my disapproval of one kind, I would not wish to be understood to object to all kinds of flat decorations. I have seen some, and arranged others, that have much pleased me; but I have never yet seen any style of flat decoration that would not have been improved if one or more tall vases had been substituted for a corresponding number of low dishes. The accompanying engravings will show that I am not unmindful of the risk which attends this substitution; but I know it can be done, and I am equally certain that, when properly done, the introduction of tall vases is a great improvement to the appearance of a dinner-table, while they are not in any way objectionable to the diners.

In my remarks in your first number,* as to the information that should be furnished in the schedules sent to intending competitors for prizes for dinner-table decorations, I mentioned that they ought to be informed how many persons were supposed to be dining at the table. I now go further, and say that the arrangement of their seats at the table should also be indicated; otherwise the decorator cannot tell whether his tall vases are, or are not, intercepting the view. On reference again to the illustrations, it will be seen that between the crossing thick lines in the middle of the tables there are interspaces, in which there is room to describe circles varying from three to five inches in diameter. It must thence be patent to every one who has had patience to follow me, that an object of any height that will stand in one of these interspaces without overlapping the lines of sight, may be placed there without inconvenience to any one at the table.

It will also be seen, that no tall object can be placed in a line down the middle of the table when the diners are seated as in Fig. A.—and that no tall object can be placed in the centre of either table; but that in the case of a party being seated as in Fig. B., there are four interspaces in the middle line of the table where tall objects might be placed.

W. T.

Instructions for the Growth of bulbs in Windows.—The following excellent directions on this subject, issued in the form of a neatly-printed circular, have been furnished by Mr. J. C. Niven, curator of the Hull Botanic Garden, to the Hull Window-Garden Society. Let us hope that the example may be followed in other places:—

Such bulbs as Crocuses, Tulips, and Hyacinths may, with a little care, be grown in any window, on which the morning, mid-day, or afternoon sun shines, and all the more successfully if the window be under the influence of all combined heat and light. If the window be under the influence of all combined heat and light: do not now lose a day. Those who have a few old flower-pots should have them well washed; the best size will be four to six inches in diameter; but, really, the size is more to be regulated by the width of the windowledge on which they are to stand than by anything else. If you have a broken pot that is useless for plants, reduce it to small pieces, place one of the largest of these above the hole of the pot used for planting, and above it a dozen small pieces. Falling the old potken take a handful of cinders from below the fire grate, and drop them into the hole. On the cinders put a bit of a broken brick, that will do to cover the hole in the bottom. It is almost necessary to have a bit in his trouser-pocket; in either case, what we aim at is drainage. Fill the pot thus prepared with the soil, as distributed ready for use, to within one inch of the top; gently press it down, and make good any deficiency caused by the pressure; then place the bulb (say three, four, or five, according to the size of the pot) on this surface, gently pressing them down; but if the roots are protruding let them stand upright, and push them up into the soil. This is done with the thumb between the bulbs so as to fix each in its place firmly. In the case of Crocuses, at this season, the bulb should just peep out above the soil. In this operation, take care of the side buds, not to break or injure them, although they do not produce flowers, they contribute leaves, and leaves are pretty, as well as useful. Tulips may be treated in the same way; but Hyacinths should have, if obtainable, a little sand below the bulb, to assist in the development of their roots; and the upper surface of the bulb should be just above the level of the sand.

But some may say we have no flower-pots, and cannot afford to get any; well, I'll give you a substitute. Have you not an old basin or a soup plate? Perhaps you say yes, but it is cracked. All the better for that; it will allow a little of the superfluous water to run out and a little air to come in. The soup plate will suffice, so you must make a miniature mountain of it, finishing with a hollow at the like side, so that the water may collect there, where water can be poured and sink into the body of the soil without singeing your fingers. Another substitute—don't laugh! An old supernumerary teapot, whose spout, possibly, has come to grief, or, perhaps, the handle—if both are gone, all the better. Make a hole, where the handle was inserted, just sufficiently large for the buds to fit snugly, and before filling up with soil insert a Crocus in each of these holes from the outside; top up the Crocus or any other bulb, and I will guarantee when their sweet-scented leaves are gracefully down the sides of the pot (though it loses its former appearance) it will still answer its new purpose to a T.

The operation of planting finished, give them a nice watering, not a deluge (wise folks don't fill the pot when they make the tea)—you may at once place

them in the window; but it would be better to give them about three weeks in a cupboard in the dark—mind, not one beside a fire. Under the influence of the dark they will make roots. During this time they will want watering once or twice, and when the window is possibly twice a week; but until they show green leaves and the colour of flowers, they will very rarely need to be watered at all. When they are in bloom, on a genial summer day give them plenty of air—open the window wide and close the door—it will do both you and them good. When done blooming, put them on the outside sill, where the leaves will get their full growth, and under these circumstances water them every day. Having made their growth, and the leaves beginning to wither, stop the water supply, but not kill them. For the summer they may be placed in a corner of the yard, or if you have a garden, plant them up round the rim in soil and leave Nature to take further care of them till next November.

Another Suggestion.—Your pots, as I before stated, will be on the outside sill; if they are large pots, place among the Crocus roots, about the end of March, two or three seeds of *Convolvulus major*, *Canary Creeper*, or even *Nasturtium* or *Scarlet Runner*, stretch a piece of wire or twine up the side of the window, and train up the young growing shoots. With a little ingenuity you can easily overtake them, when they are very small, then let them hang in natural festoons. If your pots are small get larger ones, and manure in the bottom (say two or three inches thick), place the small crocus pots in these, and if there is room fill up round the sides with manure or sand; so arranged, your seeds will thrive and flourish without disturbing your bulb.

If you have had to fall back on the teapot before alluded to, place it in an old broken basin, fill round with manure, so as to rise above the holes where the spout and handle were. The root of the strong feeding seeds from between the holes will soon find their way out, and if you succeed—and I am sure you will—may I not ask if I have not pointed out a use for the supernumerary teapot never dreamt of in the philosophy of the staunchest teatotaler?

CULTURE OF PLANTS IN ROOMS, DOUBLE WINDOWS, &c.

For room culture a selection must be made of such kinds of plants as are natives of countries the climatic conditions of which bear some resemblance to the temperature and air which we can offer to these plants in our rooms by means of any contrivances which can be adopted for this purpose; and, in the second place, an intelligent care and regard must be had to the natural requirements of the plants in connection with the peculiarity and special influences of room atmosphere.

For dwelling-rooms, the temperature of which ranges from 55 deg. to 60 deg. Fahr., a judicious choice will naturally select plants which are natives of quite a different region from that inhabited by plants which are suited for rooms, corridors, and staircases, which in winter enjoy a temperature not much above the freezing-point. Here we shall only make the general observation that for regularly heated rooms plants from warm, almost tropical, latitudes must be selected, and amongst these those in particular which do not grow in an atmosphere constantly saturated with aqueous vapour. Plants which require such an atmosphere can be grown in rooms only where arrangements have been specially provided to supply them permanently with the heat and the moist atmosphere of a regular stove. For rooms which have a winter temperature of from 50 deg. to 65 deg., and in which no special arrangements have been made, use may be made of the hardier ornamental plants, and also of some of the freer-blooming temperate stove plants, to which may be even added a few stone plants from moderately warm latitudes. In particular parts of the heated room separated from the rest by a glass partition, plants from the temperate moist stove may be cultivated; but plants of this description from the tropical regions proper will not succeed in a room. Corridors and staircases which are just secure from frost will be most suitably adorned with hardy evergreen plants from temperate regions, and also with the so-called cool conservatory plants, while rooms which are kept above the freezing-point offer the most suitable locations for wintering plants from moderately warm regions, or greenhouse plants intended to bloom in summer. The greater number of the plants of these latitudes, the culture of which is best carried on in low, cool-houses, near the glass, such as the *Ericas*, *Epicrises*, and the tender *New Holland* plants, are not adapted for culture in rooms.

The greater number of plants intended for room culture are, of course, purchased by amateurs from nursemen. Now there are plants well adapted for room culture which, nevertheless, usually suffer more or less when transferred from the stove to a room; as in the former, they mostly enjoy a moist, warm atmosphere, and a larger amount of light. But in the inhabited rooms of a dwelling-house they can only be supplied with a moist atmosphere, and a sufficient quantity of light in certain parts of the room especially prepared for them, where they cannot serve for ornament—as, for instance, in the double window.

We know that leaves exhale less water in a moist atmosphere, and much more in a dry one. The natural consequence of this is, that the leaves and young shoots of all plants growing under the influence of the moist atmosphere of a stove have a softer and more succulent texture. In the dry air of a room, the evaporation from the leaves of the more tender plants is so excessive, that the equilibrium between the supply and the evaporation is disturbed. The result is a drying up of the leaf.

points and margins, or a shrivelling, or even total withering of the leaf. From this cause frequently plants in a short time become very unattractive in their appearance, while another consequence of the derangement produced by overtasking the organs is the decay of the younger roots and a diseased condition of the entire plant. The amateur removes these debilitated specimens, or sends them into a plant-house for recovery; supplies their place in the room with other specimens, with the greater number of which he makes equally bad practice; and so by degrees he loses all pleasure in his room-garden. Unsuitable positions, far from the light, and faulty treatment conduce alike to the same bad result, but even with the best care failure is sure to attend on plants removed from the stove into a room. Whoever wishes to grow fine and permanent specimens for his room-garden should not be disengaged if at first the removed plants become deteriorated in their appearance, but, on the contrary, let him give them a double amount of attention, so that even in the room they may acquire a fresh and vigorous habit of growth. The organs which are developed under the influence of the room atmosphere will at the same time gain such firmness and powers of endurance as will, with a moderate amount of attention, render the plant capable of becoming a lasting ornament of the dwelling. The best modes of heating dwelling-houses destined for plant culture are those stove apparatuses which supply an equable, unintermittent, and not too dry a heat. Hot-water pipes are, therefore, for dwelling-houses, as well as for plant houses, the most suitable.

PUBLIC GARDENS.

THE SQUARES OF LONDON.

WHATEVER the present condition or prospects of the squares of London may be, we should be thankful that we have them. The haunts, or rather the strongholds, of disease and pollution are rendered unsafe by these islets in our unparalleled desert of slate, brick, and flag. In them the sun shines—dimly, no doubt, from our smoke plague—the wind seems to attain a little more freedom, and trees persist in growing, no matter how badly they are treated. We have many squares in all parts of the city, but assuredly not half so many as its colossal expense requires. In the suburbs, unhappily, they do not seem fashionable with the cheap builders nowadays. These seem as if they were gradually tending to the extermination of small gardens as well as squares. If matters were arranged as with our neighbours the French, the square and the wide airy road would be laid down long before the builder came to arrange the ground as seemed best to him. They say to him: Here you may build, but do not encroach on the space necessary for public convenience; and thus they avoid the tortuous, close, and often dirty suburban roads which tend to make many of the most agreeable districts round London uninhabited by and unknown to all but their inhabitants. I know nothing more disheartening and unwise in its way than our system of mean and narrow suburban roads. In South London matters are not so bad in this respect; but just think of the road to pleasant Kew and its vicinity *via* Hammersmith! Why no person not inured from early years to such a road would willingly run the gauntlet of taking it if there was any alternative. A broad and pleasant tree-planted road through such a district would, by opening it up and making it attractive to the inhabitants of London generally, prove as beneficial from a commercial as from a sanitary and an aesthetic point of view. And if such roads as convenience and good taste demand existed in a city the size of London, squares would be of less importance. Our new Thames Embankment, for example, is better than a score of squares.

It surely cannot be necessary to point out the benefits that a square confers on the district immediately around it. All, or nearly all, our present expenditure for public gardening is on the vast parks of which London is happily the possessor. But so long as the parks are separated by miles from each other, so long must the square or other open space be of the highest importance. The advantage of a park to those who pass one hour out of two hundred in it, is not so very evident; it is far otherwise with contrivances which improve the spots in which people work and sleep. Parks for play and exercise, and beautiful garden scenery, let us have by all means; but our great want is the smaller open spaces called squares, and wide roads planted with trees. Where roomy streets are fringed with one or more lines of trees that have been proved to thrive well in cities, most of the advantages of squares are secured. But as these seem impossible to us at present, if we cannot have what we like, why the best way is to like what we have, and try and make it more worthy of our love.

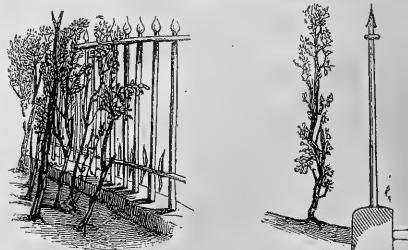

Into the history of our squares I have no wish to enter; their present condition is what is of most importance to us. We were, I believe, the first to make squares; though, judging by present

appearances, we shall be among the last to improve them. We have in London squares of various degrees of magnitude and keeping, from the West Central squares, with their fine old trees, to the new Brompton ones with their three-year-old Lilaes; from the wide West-end square to the small and dark and grimy ones in Soho or the City; but the very best of them are badly kept, and utterly unworthy of London. From Eaton or Russell Square to the "Squâr de Leicester" is indeed a deep and ignoble descent; but the stamp of neglect and ignorance is upon all. We will, now, have a look at the condition of Leicester Square in the latter half of the nineteenth century of the Christian era. When, generations hence, our descendants shall have

Leicester Square, June, 1870.

abolished smoke from their cities and made them much less effective in destroying the health and enfeebling the physical powers of the race, perhaps some of them will glance at this beautiful little scene, and look back with pity on the urban lives of their sires. An un-horsed statue lying in ignoble dust; a propped-up horse with a large basin-like hole in the middle of his back; a filthy dead-dog and dead-cat bestrewn surface; and a rusty, decayed railing, broken away in parts, form the picture. A few tattered Hawthorn bushes remain on one side, and bloom beautifully there, notwithstanding the neglect. This unhappy square is capable of being made, with but trifling expense, quite as beautiful as such little Parisian squares as that of

Margin of a London Square, with edge of plantation designed to cutoff the view; and Section of Railing surrounding Park Crescent, July, 1870.

Montrouge, which are, or used to be, perfect gems in their way. It is somewhat unfortunate that our French friends should have the worst of all our squares in the middle of their London quarter. We can hardly expect that they, too, will agree that London is the centre of civilisation, so long as we damp their gay souls by such scenery as this. Let us turn from this disgraceful scene—a long-standing evidence of the feebleness of our vaunted system of local self-government, and glance at the condition of our squares generally.

So far as I can discover, no clear idea of what a square should be has ever been possessed by those who designed them. The chief feature they have in common is a very dirty and very ugly crowded

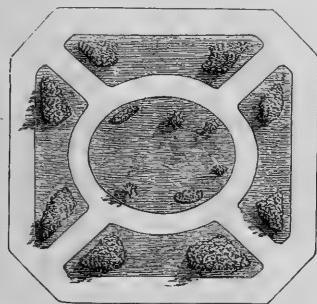

bank of Lilac and other common shrubs just within the margin; so that it is, in most cases, impossible to see into them. It has been assumed that the right thing to do was to hide the persons who now and then wander into the square from the passers-by; and thus the only fresh and pretty spots in many parts of the town are lost, so far as their general effect is concerned; and all from mistaken ideas as to the wants of the few persons who walk about, ghoul-like, in the musty and dripping shades of the interior. There is nothing in any of our parks, there is no feature in any of our public gardens, more beautiful and effective than even our small squares could be made; but little can be done so long as the absurd system of cutting off the scene from public view, and from the view of the persons who inhabit the square, prevails. There are squares in London in which views, almost Arcadian in their beauty, could be made; yet, from the windows of the very persons who support them, you can see nothing but a struggle between Privet and Lilac. Two of the finest weeping Ash trees that I know of anywhere are near the margin of Brunswick Square, but they are so surrounded by the inevitable

Structure in centre of a London Square, 1870.

scrub of mean bushes, that they are rarely recognised by the passer-by. Cleared around and surrounded by well-kept turf, they would prove ornaments to the whole district. But it may be urged that the squares are private property, and that their owners have a perfect right to keep them shut out from public view, if so disposed. Even so, it is quite possible to do this without making the margin inviting as a depositing ground for miscellaneous rubbish, and without wholly concealing the finest objects they contain.

By allowing the grass to venture near the railing here and there, and dotting it with flowers and isolated shrubs, so as to permit of pleasant peeps into the interior, quite a new aspect would be given to our now gloomy squares, and the change would not by any means involve the destruction of all privacy. No conceivable harm could come of making these little gardens attractive to the public; and in doing this they might be made tenfold more so for those who have

Plan of small square, with grassy open centre.

"a right" to these small fenced morsels of God's earth. Notwithstanding the great number of persons that often crowd into a Parisian square, there is not one of the squares of that city that is not a far more attractive object than any London one, and I have not the slightest doubt that if we could drop the square of St. Jacques into our West Central district, there would soon be a general desire on the part of the owners of our squares that they should be disposed in like manner. In that small, much-frequented square I have seen far more rare and valuable plants in masses in the open air than are exposed in our great public gardens here, and without the least danger, though crowds frequent the place from morning till after dusk.

Another important feature of the arrangement of our squares, and one which, like the filthy and crowded marginal shrubbery, is common to nearly all of them, is the disposition of the central portion. The ground is usually so small that it is desirable to make the most of it. The best possible course to make it look mean and contracted is to raise a platcan, and on this build a structure varying in appearance, as it looms through the trees, from the aspect of a wooden summer-house to that of a bathing-machine. Yet this is what is done in the majority of what may be termed the "best" London squares—in Cavendish Square and Lincoln's Inn Fields, for example. The eye is thus fixed on the contemptible objects in the centre, an agreeable spread of turf is made impossible, and one cannot feel the beauty of the trees or shrubs.

It is most unwise to desire uniformity in any art, but if there is one principle which deserves being engraved on the mind of every person who has the care of one of these squares, it is that the true way to obtain the best effect is by keeping the centre open and, grassy, untortured by walks, hedges, or beds. By leaving the centre open and working in all our flower and tree beauty round the margins, we may in these small spots of ground make pictures to charm every beholder. The arrangement I mean will be seen at a glance in the preceding plan of a small square. It is by no means given as a model, but simply to explain the principle. The fringes of the central lawn might be planted in as varied a manner as possible. In large squares the form of the lawn need not be regular as in this case. But it is only when the good effects of the sweet fresh lawn in the centre are seen that its excellence can be appreciated; a plan cannot show it.

(To be continued.)

STREETS AND GARDENS OF SALT LAKE CITY.

In the laying-out of their city the chiefs of the Mormon sect have displayed a very high kind of capacity for the great work of town-founding. They wisely took warning from the bad effects produced by the narrow thoroughfares of the older cities and their grimy aggregations of closely-built, wretchedly-constructed, and ill-ventilated dwellings which are frequently almost without the smallest space of back yard; and certainly free from the slightest attempt at reserving sufficient space for anything deserving the name of a garden.

In order to avoid these glaring evidences of the absence of thoughtful judgment in the original foundation of the great cities of the world, it was determined to make the principal line of roadway (to serve as a public promenade) of such noble width as to leave to the dwellings on either side almost as ample a supply of light and air as if they were situated in the open fields. And in order further to secure the aspect of the city from becoming one of mere brick and mortar, to the utter exclusion of natural beauties, specimens of the best native trees were planted along each side of that spacious road as soon as it was laid out.

In accordance with such views the houses were built at a considerable distance apart, and each was surrounded by an acre or more of garden-ground. These arrangements have necessarily rendered Salt Lake City one of the healthiest cities of the world; although in some parts of "Main Street" the frontage has become so valuable that new houses have filled up the interstices and form a nearly continuous line. The gardens are always trimly kept, and often make a rich display of flowers of kinds but little known in this country, though most of them would probably thrive well in our climate. These gardens, by persevering culture, are also rendered very productive in many kinds of well-grown vegetables; and the land surrounding the city, by unceasing and untiring industry, is made to yield abundant crops of the leading cereals. The Mormons are not a poor people in all that ministers to the comforts of existence, though they have no "money"—and mainly obtain from each other what they require by an ingenious system of barter. The course of legal prosecution entered upon by the American Government will, in all probability, lead to the extinction of those features of Mormonism which are an offence to Christian morality; and Salt Lake City may then form the nucleus of one of the most beautiful American cities of the Far West.

Hampstead Heath.—The covenant sum of £15,000 has been at length paid over by the Metropolitan Board of Works to Sir John Maryon Wilson, as lord of the manor of Hampstead, in purchase of all his rights over this heath, and the deed has been signed and sealed by which that open space is now held, under the name of "Hampstead Heath," in trust for the public. The Metropolitan Board of Works has also borne the legal and other incidental expenses of the transfer, amounting to £2,000 more. In commemoration of this transaction a number of the inhabitants of Hampstead and the neighbourhood have lately raised a subscription of some £650 as a testimonial to Mr. Philip H. Le Breton, barrister-at-law, chairman of the Hampstead Vestry, and representative of that parish in the Metropolitan Board, by whose exertions the heath was the gift of the Corporation, complete with tea and coffee service, a gold watch, and a purse of £500, was formally presented the other day to Mr. Le Breton at a public meeting at the Hollybush Assembly-rooms. Thus, within

five miles to the north of Charing Cross, as noticed in another part of our paper, some four hundred acres of open ground have been set apart by the public, which, for the first time, will be easily accessible within five miles. Indeed, both on the north and south of the metropolis, notwithstanding its enormous growth, pedestrians may still find within a moderate afternoon's walk all the refreshment of pure air and fine country scenery. The considerable hills which skirt the valley of the Thames on both sides are in this respect of immense advantage to London. They are sufficiently distant to secure the city from being cramped in its growth, and to allow ample movement of air, while they are situated very conveniently near the point of the metropolis, so as to be inhabitable. London creeps up to the foot of these eminences, and then, as if deterred by their height and steepness, throws its arms around their base, and thus leaves a portion of open ground still accessible to the lungs and limbs of its over-crowded inhabitants.

Convict Gardening in India.—An interesting report, says the *Times*, of the administration of the Nicobar Islands—our great convict settlement—has been issued. At the end of 1868, Colonel H. Man began what is called “The Royal Dover Garden” at Haddo, Port Blair, as a nursery for fruit and other trees, vegetables, &c. About 350 acres of land have been taken up for this purpose. The Superintendent of the garden has, in the course of the year, sown 7,000 varieties of fruit and other trees; 74,500 plants with an estimated average of six suckers each. He has sent out from the nursery 5,600 more, and there remain close on 50,000. English and other vegetables also have been raised during the year. Of course, this wonderful progress towards social comfort had been made chiefly with a view to the free population, but the ticket-of-leave men and free cultivators receive a share of the benefit. Their monthly average number is 174, all of whom are permitted to work as they please and sell their produce in the market. The market is a high-class one, and is controlled by the commissariat, that market, with regulated prices, is always open to them. If the progress indicated in this report continues, the settlement of Port Blair will before long become rich in fruits and other productions of the soil. The Governor of Madras has contributed to the garden during the year a present of 1,000 plantain shoots, 100 pummeloes, 1,000 oranges, 1,000 limes, 25 pomegranates, and 25 jact fruit.

Victoria Park.—The Chancellor of the Exchequer received at Downing-street, the other day, a deputation relative to the proposed building on the reserved land about the park. Mr. P. T. said that the Government would not consent to demand of the land as of right, by the entrance of the Government in fact and in prevent the building of the ground (some thirty-five acres), or at least to suspend the building operations, so as to give time for an appeal to Parliament. It was said that as many as 150,000 persons had visited the park in one day. The Chancellor of the Exchequer said that the deputation had shown what he never doubted, that it was most desirable that their object should be attained. But he had to look upon the matter from a different point of view. The money for the proposed advanced by the Government to buy the reserved portion of which was to be given to the Board of Works for a park, and another to the Woods for building. That land was therefore the property of the people of the whole country, but they asked him to give it to the people of the East-end. The same request was made to the Board of Works for the reserved land of Finsbury and Southwark parks, but they said the interests of the ratepayers would not let it be granted. He had to put the people of these islands in the place of the ratepayers and say the same thing. If the inhabitants of the East-end wanted this land, they should put their hands in their pockets and buy it.—*Times*.

THE MARKET-GARDEN.

SIXTY YEARS AGO.

At the commencement of my horticultural experience but little was known of gas, steam, or hot-water apparatuses for the heating of either plant or forcing houses, and on account of there being a heavy duty on the materials usually employed in the construction of glass houses, it was not until that was removed that they made much progress. The glass, too, of those days, was coarse, spotted, and of bad colour, and in many houses the panes were lapped in casement lead—in short, frames and pit lights were generally constructed on this principle. Even near London, where the most improved methods of hothouse building might have been expected to be found, market gardeners had almost all their frames and forcing lights glazed either wholly in casement lead, or had the squares of glass lapped with that material. In the course of time some alteration was made in the duty paid on glass—instead of being paid by measurement it was paid by weight. A clearer white glass called “crown glass” then came into use, but it began to be manufactured so thin, to avoid as far as possible the duty, that breakages became extensive. The sash-bars were therefore placed closer together, so that, instead of being seven or eight inches apart, the width was reduced to from four to five inches, which was not only considered safer and stronger, but also furnished a pretext for using up odd bits of glass. This kind of glazing had obvious disadvantages, notwithstanding which, however, many span-roofed and other structures were erected on that principle, in which grapes, pine-apples, salads, early vegetables, and the whole round of garden productions, both as respects plants, fruits, and vegetables, were grown in considerable perfection. When, however, the glass duty was repealed, an immediate improvement in the quality of glass took place. Nevertheless, when we had got it cheap and good, it was reported to burn, scald, and spoil both foliage and fruit.

Such objections, looked back upon, now astonish us, and they probably originated in the fact that more was then attempted under glass than the experience and skill of cultivators were equal to, for new and, comparatively, but little known features of cultivation every day presented themselves. Elegant glass erections began to

be built, in which comparatively little timber was used, and they were glazed with fine, large, clear glass, to admit plenty of light. To stay progress in this direction seemed impossible, but now complaints were raised against colour; and glass of various colours was tried; but in the end clear glass prevailed. Intensity of light Nature usually, if left to herself, counteracts by an increase of humidity; and atmospheric motion she always supplies. I, therefore, endeavoured to follow the lessons which she taught; and this I did with considerable success.

Since that time, however, the principles of ventilation have been taken in hand, and greatly improved. More humidity has been supplied, and, consequently, greater health and vigour have been secured. Few complaints are heard now as to colour; still, there is no doubt, that a slight tinge of blue in glass is better than the clear white sort.

Vineeries, pineryes, and plant-houses sixty years ago were all lean-to's, span-roofed glass houses being then unknown. They were heated by cumbersome fues, very often so badly constructed that, for want of a brisk draught, one end of the house would be parched up and the other cold. In many localities, the quantity of fuel required for these fues was a serious consideration. Coals were dear, and often far to fetch; indeed, in many country establishments no coal was allowed for hot-house fires; wood, peat, turf, and balls of stiff clay, had to be used, according to the locality. The balls of clay were a pretty good thing to bank up with, or place on a good wood fire the last thing at night.

In those days few persons grew pines—their system of culture was slow, and at all seasons they maintained a dry heat. Therefore, both plants and fruits became nests for scale and bug, and, as might be expected, the fruit was poor and imperfect. Grapes were generally very badly cultivated, indeed; they were all grown on what is now termed the extension system: one vine to a house; or, if two were planted, one would be a black and the other a white variety. The whole surface of the glass was generally covered with a network of wood such as it was, and leaves with but a few small miserable bunches of fruit of poor enough quality. Their theory was—and no theory was more persistently practised—that an abundance of wood ought to be left when pruning, the idea being, that plenty of wood would be sure to produce abundance of fruit. Another idea was, that all vines must, if possible, be turned out of the house in autumn, or that the house must be uncovered, in order, as it was averred, and which was also abundantly practised, that the wood might be properly ripened. Stoves and greenhouses were generally furnished with grape vines, one to each rafter, oftentimes each being a different variety; and these, too, were turned out to ripen their wood. This practice of having part of the vine in a hot-house, while a large portion remained outside, was, I need not say, continued for some time. The vines were planted outside, and the rods were taken in, and trained up the rafters, thus suddenly exchanging a wintry atmosphere for the heat of a pine stove. The consequence was, that some vines did not even break, others pushed away weakly, and were sometimes cut back, in order that a new growth might commence from the part which entered the house. This system was actually practised as late as 1837, when the memorable Murphy winter came upon us; and killed almost every vine exposed in that way to its action. That year, when they were placed inside, to produce their growth and crop, they were found to be dead—a fact which taught cultivators a lesson for their future guidance. I should, however, mention that a few persons, more intelligent than their neighbours, had made some years previously considerable improvement in vine culture, also in the varieties cultivated, and that they had even ventured on the one-rod and close-pruning system, so generally practised since by good grape-growers. I have noticed of late that even in the present day we are not without advocates of the old extension system; but whether it may prove a step in the right direction or a retrograde one, time will prove.

Early cucumbers were generally grown in those days in frames, on beds of well-wrought fermenting stable dung. Leaves were sometimes used in country gardens, when they could be procured, and preserved by those who were well up in the cultural skill of the period. The bed was thoroughly lined and wrapped up with the same materials, outside of which were placed thatched hurdles, evergreen boughs, or faggots, or other material capable of breaking the force of driving wintry winds; thus maintaining as much as possible, a uniform temperature within—no easy matter under such circumstances. Everlasting attention, in fact, was required to cultivate cucumbers so as to be able to cut good fruit from the 3rd to the 10th of March. Those able to do so were considered to be fortunate. Early cucumbers and melons were the only specimens of horticultural produce exhibited then, and little clubs or meetings of gardeners, and others interested in horticulture,

used to be held in certain localities for the purpose of raising by subscription a small sum to be offered as prizes at such shows. The prizes, which were generally in the shape of some simple and useful article, such as a silver teapot, milk jug, half-a-dozen teaspoons, pair of tablespoons, and such like, were, for the most part, three in number, and in value varied according to the amount of the funds subscribed; they were offered for the best three threeps or dish of cucumbers. These little cucumber meetings, or exhibitions, of which the greatest number was held from the 3rd to the 10th of March, generally took place, as had been previously agreed upon, in the room of some hotel or tavern centrally situated or most accessible to the greatest number of exhibitors. After the prizes were awarded, a dinner was provided, after which a friendly discussion on gardening matters took place, with a general interchange of seeds, cuttings, &c., for, as was very often the case in those days, there would not be a nurseryman or seedsmen within many miles—indeed, there were but few if either in the whole country.

I should mention that, in order to obtain these early cucumbers, it was the custom to sow the seed from the 3rd to the 12th of the previous October, so that plants might be got strong enough for ridging out, or placing in their permanent positions by the middle of November. The beds, made as has just been described, were from four to five feet in height, and when new linings were put to them, which was often the case, great care was always requisite to keep the least sourness or gaseous fumes from getting inside the frame—such was the constant precaution and anxiety then required to get fine cucumbers by the first week in March. And in attempting this there were often many “break-downs” through not having always in readiness a supply of fresh, sweet, and well-worked materials for any emergency, as well as through other causes. Those who really did succeed in those days were considered to be at the head of their profession, it being generally the case that the successful man was a patient, persevering, and attentive cultivator, in all branches of gardening, as well as orderly and methodical in his habits. My first employer, near London, was an extensive and successful cultivator of early cucumbers. There were then but few others who attempted to grow them on a large scale, on account of the trouble and expense they entailed, together with the uncertainty of success. There being, consequently, but little opposition, cucumber-growing was a profitable speculation to the skilful cultivator. A brace of good cucumbers in March always realised two guineas, and sometimes fifty shillings. The generality of growers and market-gardeners did not attempt to prepare for cucumber culture till January or February: the seed was sown and strong plants obtained in time for ridging out in March; fruit could then be cut by the end of April or beginning of May. In large market-gardens mountains of London stable dung were collected, the first use of which was the protection of frames for forcing early asparagus, seakale, early celery and various other things; some hundreds of lights were also in use all winter for the protection of cauliflower and cos lettuce plants, by which enough were grown to plant thirty, forty, or more acres. By the time these frames were cleared from their winter occupants we always took care to have in readiness some of the litter well wrought in succession heaps, so as to make up at once our succession hot-beds, to have also the plants in readiness for turning out into the frames, and more sown to succeed them. Thus by the middle of April or beginning of May, I have had under my care a thousand lights of cucumber plants. About the first week in May we would have the cucumber plants strong and ready for planting under hand and bell glasses, at that time much used for protecting cauliflower and lettuce through the winter. We had generally above three thousand of these glasses in use for such purposes, the whole of which, by the first week in May, would be turned to account for cucumber culture. Between the rows of bell-glasses under which the cauliflowers were planted, a space of ten or twelve feet was left for winter spinach, as well as for the sowing in December of early radishes. This space, when sown, was covered with straw for protection. By May these crops were generally gathered, when a line was drawn down the centre of the space; in this the pegs used for giving air under the bell-glasses, were stuck at regular distances apart; two strong men then commenced with large market-garden spades to make holes or pits, row after row, where each peg stood, first placing the peg on the right-hand side of the hole. A gang of men was then employed loading and wheeling hot dung, of which a barrowful was thrown into each hole. A man followed with a strong fork to shake and shape the litter into form; he was succeeded by two more men, who, with their spades broke up the soil, which had been thrown out of the pits and placed it on the top of the dung. A woman then put the glass on the top and placed the air peg on the south side of it, to be in readiness. Two more women brought the plants which had been previously taken from the stove and hardened off, and placed a pot against each glass. These were

succeeded by the foreman, who turned the plants out of the pots and planted them. A woman then followed replacing the glass, pressing it down, and drawing a little loose earth round the rim to prevent the admission of air. Thus methodically and like clockwork was the whole work gone through. By the time the cucumber plants had grown sufficiently large to admit of their running out from under the glass, the whole of the spinach and radish crops were cleared, should any have remained. The beds were then rounded off, and mulched with litter shaken from the stable dung. In this manner tons of splendid cucumbers were daily grown for twelve or fourteen weeks to supply the London market. The cucumbers grew so vigorously and productively in those years that I cannot help looking back to the time, and wonder why that, during the last thirty or forty years, no such vigour and fruitfulness are to be seen. A canker disease has attacked them, as the potatoes have been attacked, and from which all out-door-grown cucumbers suffer more or less.

Gherkins were at that time grown in the Fuham and Battersea fields, and in Bedfordshire by acres. The seed was sometimes sown broadcast, and the young plants, when sufficiently advanced, were thinned out by hoeing; or it was sown in a seed bed, with a little bottom heat, in the open air, and the young plants were afterwards transplanted in rows. The produce was generally gathered by women, packed in half-bushel sieves or bushel sieves, and forwarded to London in immense quantities. A large quantity was also annually sent to the different pickling establishments, and to the oil shops that existed near the river side, where they were pickled in casks, jars, and bottles for exportation. In order to get rid of the surplus crop, and the fruit which had become overgrown, they were collected and put in sacks or baskets, sent to market, and sold for two-pence or threepence per dozen; even a penny per dozen would not be refused at times, so glutted would the market very often be with them. Bushels of gherkins might have been seen at the street corners and street stands of London, evidencing the relish which the people had for them, even only forty or forty-five years ago. Although cucumbers have not grown well in the open air for many years past, yet since the establishment of hot-water apparatuses as a means of heating glass houses, they have been inexpensively and successfully grown with but a small share of the trouble and anxiety which characterized open-air cucumber culture sixty years ago.

Melons were never, in my remembrance, very extensively grown by the London market-gardener, owing to their requiring more particular attention than cucumbers, and also on account of their being longer before they produced any return, and then not so profitable a one as the cucumber; some cargoes of Dutch melons, too, were sent to this country, which lessened the sale of what were grown here. Steam vessels also began to venture abroad, and brought to our markets melons and other fruits in great abundance; and imports of this kind have been year by year steadily increasing. Gentlemen's gardeners, however, grew melons in those days, and had them for exhibition, such displays generally taking place about the middle of May. The fruit was then, as now, cut open, in order to test its quality. And I must say that I have seen, more than fifty years ago, as fine melons in size, shape, and flavour, as are to be seen now. In order that good melons might be produced in the market gardens early in May, it was necessary that the seed should be sown about the beginning of February. There were a good many varieties in cultivation, amongst which were an early, fair-sized, scarlet-fleshed sort, called Cantaloupe, a beautiful green-fleshed kind, named Egyptian, and a handsome rock-scarlet-fleshed variety, grown as a summer crop, after early frame carrots and potatoes.

It is a singular fact that vegetable marrows were not cultivated in this country sixty years ago; and, for some time after their first introduction, but little use was made of them as a culinary vegetable; they were looked upon more as a curiosity than as a useful part of garden produce, though now so much appreciated. They are certainly much superior to summer-grown turnips, either cooked whole or mashed.

Late of Bicton.

JAMES BARNES.

Richmond Sewage Works.—In reply to the advertisement of the Richmond Sewage Committee, offering a premium of £500 for the best practicable scheme for the sewage of the parish, upwards of twenty schemes were submitted; and at the last meeting of the committee the premium was awarded to the authors of the scheme marked “C. E.” found to be Messrs. Goto & Besley, of Great George-street, Westminster. The system proposed by these gentlemen is the same as is carried out by them at Rio de Janeiro, where it has been in operation for the last seven years, to the drainage from a population of about 400,000. The sewage is decomposed in a series of subplots of aluminae, charcoal, and other materials, and the effluent passes through long porous pipes, where the solid matter is separated, and the effluent water, after being strained and filtered through charcoal filters, passes off clear, and free from smell. There are special appliances for drying and removing the solid deposit, prepared for agricultural purposes. The high part of the town will be drained by gravitation, and the sewage from the low part will be pumped. The cost of the deodorising works is estimated at £20,000, and the intercepting sewers at £5,000, or a total cost of £12,900. The Sewage Committee have given the necessary notices for obtaining the land for the works.—*Builder.*

[DEC. 16, 1871.]

THE AMATEUR'S REMEMBRANCE.*

In-door Department.—Remove Chrysanthemums from greenhouses and conservatories as they go out of bloom, and fill their places with plants from the forcing-pits. Camellias, Epacries, and winter Heath will soon maintain a certain amount of gaiety, as will also Cinerarias, Neapolitan Violets, and those pretty-berried plants, the different varieties of *Solanum capsicastrum*. In cool-houses keep up a little artificial heat on dry days in order to be able to give air. Water Cinerarias pushing up flower-stalks with liquid manure, and fumigate if green-fly appears. Where no better accommodation can be found for the beautiful-leaved Coleuses than a greenhouse, they should be kept at the warmest end. Camellias, now swelling their buds, will be benefited by being watered now and then with weak liquid manure. Auriculas, Polyanthus, and Carnations, in pits, give as much air to in the daytime as possible, whenever that can be done, taking the sashes entirely off; but if wet, keep them on, tilted back and front. A temperature just above freezing will suit them perfectly. Water seldom; but thoroughly when they are really dry. Hyacinths, Tulips, Lily of the Valley, Crocuses, and other bulbs, bring on in the forcing-pit, in a temperature of not less than 60°. A similar temperature will suit Poinsettias, Begonias, Lilacs, Roses, Deutzias, Rhododendrons, Azaleas, and plants of that kind required for the decoration of warm conservatories or greenhouses; and as soon as there is room introduce fresh supplies for succession.

Fruit and Forcing Houses.—Vines starting, if planted inside the house, should receive a good soaking at the root now and then with tepid water, to promote underground growth. Let the rods hang horizontally for a time, in order to induce them to break more regularly than if they were fastened up in their proper positions. When forcing is about to be commenced, and the roots are outside, if not already done, let the border be well covered with fermenting material. Prune, and paint the vines with the following composition, viz.:—Sulphur and cow dung, or clay, equal parts, mixed with tobacco-water, first stripping off all loose bark from the old wood. Trees in orchard-houses may now be pruned, taking care to shorten back to a wood bud, and dress the trees with Gishurst compound; at the rate of four ounces to a gallon of water. When re-potting, slightly root-prune such trees as have been too luxuriant; and weakly ones encourage with fresh, good soil. Where these constitute storerooms for bedding plants, Pelargoniums in pots, Fuchsias, and things of that sort, a temperature of some 40° or so must be maintained to keep all safe, giving air every day in mild weather.

Fruit and Kitchen Garden.—Pear trees on walls, prune and nail. After pruning trees on espaliers, see that the stakes are in good order, or, better still, substitute those figured in our last number. Orchard trees of all kinds prune, not forgetting even damsons which are often neglected in this respect. Planting of all kinds bring to a close as early now as possible, and when the trees are up, trim in some of the strongest of the roots with a sharp knife. Gooseberries and currants should have their buds dusted on some damp day with soot and quick-lime or guano, to keep birds from feeding on them. Top dress with manure, either “pointing” it in now or in spring. Select such strawberries as are intended for early forcing, dress them and plunge them in a leaf-bed in a cold pit, keeping them about a foot from the glass. They can be introduced into a little heat in succession as wanted. In the kitchen-garden, peas or beans coming through the ground, protect from birds. As soon as it can be done mould them up a little to preserve them from cutting winds. Ground from which roots have been lifted should, when being dug, have a good dressing of lime to kill insects, and should be turned up rough to be pulverised by the winter's frost. When it can be done, stir the surface-soil among growing crops. Endive and lettuces take up on dry days, and store in a dry, airy shed. Calendulas or lettuces under glass should have air given them whenever the weather is at all favourable. Straw covers or wooden shutters should be in readiness in a dry state for purposes of protection when wanted. They will be found useful for covering pits or frames in severe weather.

J. M.

How to Prevent Weeds from Growing on Walks.—To one gallon of water, add about half a pound of air-slacked lime; boil and incorporate them well together, and apply them with a common long-handled whitewash brush while the surface on which the application is to be laid is in a dry state. This will dry in a few hours if applied boiling hot, and the colour will be unobjectionable. Before applying the mixture brush off any loose earth that may lie on the walk; small growing weeds no notice need be taken, as the hot air kills them instantly. Walks thus treated cannot fail at all times to give satisfaction.—J. BARNES.

* Complete general calendars, written by some of the most able gardeners in the country, are published in THE GARDEN in the first issue in each month.

RABBIT-PROOF PLANTS.

ALLOW me to add the following to the list published in your first number, on page 9:—

<i>Acanthus spinosus.</i>	<i>Pampas grass.</i>	<i>Peppies (tree and others).</i>
<i>Buddleia glabra.</i>	<i>Rhododendron.</i>	<i>Tephritis virginalis.</i>
<i>Cotoneaster macrophylla.</i>	<i>Hardy ferns (all kinds).</i>	<i>Heaths (hardy).</i>
<i>Juniperus procumbens</i> <i>sabina.</i>	<i>St. John's Wort (<i>Hyper-</i> -<i>cum</i>).</i>	<i>Jasminum nudiflorum.</i>
<i>Potentilla fruticosa.</i>	<i>Leycesteria formosa.</i>	<i>Spiraea armeria.</i>

During a ten years' residence in Norfolk, where rabbits are very numerous, these were generally free from their attacks. I do not say that, during a severe winter, if there was no other food to be got, some of these plants would not be nibbled at; but I have frequently seen common laurels, thorns, hazels, &c., killed to the snow-line by their depredations, and these not touched. Rabbits in different localities may, however, have different notions as to food. In Norfolk I found them particularly fond of dwarf perpetual roses; and frequently choice hollies used to suffer a good deal from their attacks, while rhododendrons, which grow in the woods amongst them, were never injured. The pampas grass is a first-rate plant for planting largely in ornamental game covers.—E. HOBDAY, *Ramsey Abbey*.

—HUNGRY rabbits, like hungry dogs or starving men, will eat almost anything that can be masticated and swallowed. Rabbits, as a rule, prefer to nibble over a pasture that contains short, sweet, wholesome, grass, and a proportion of clover, dandelion, and daisies, but in and about woods where rabbits are numerous the grass, from being closely and constantly eaten off, gradually disappears, and at the approach of winter is succeeded by moss, a very cold, watery, and immitigating substitute; then rabbits are driven to seek food from other sources than grass, and the bark of small trees, the leaves, stalks, and bark of shrubs, and the protruding roots of forest trees are eaten almost indiscriminately. Amongst evergreen shrubs, rhododendrons and box are generally avoided, but I have known newly-planted hybrid rhododendrons to be partly eaten by rabbits. The elder is distasteful, and American azaleas are avoided. I have frequently seen yew trees backed; mahonias are devoured in these woods as soon as planted; and periwinkle, which is named amongst rabbit-proof plants, is generally eaten to the ground in severe weather. Some of the bulbs and flowering-plants named by your correspondent may well escape in winter, because they are not seen above ground, and where they grow, other, more agreeable herbage appears, so their immunity consists in being inaccessible in a hungry time. Where rabbits are permitted, the fact that they require food daily like other creatures should be recognised. In the absence of wholesome food they will eat simply what they can get. A certain portion of grass land should be retained for them, and managed accordingly; a few acres might be wired round, or, to be more explicit, surrounded with wire-netting, to the exclusion of rabbits until the approach of wintry weather, when it could be thrown open for them. If this cannot be done, and frosty weather sets in, when the mischief to shrubs is consummated, trimmings of quick hedges should be scattered about, and an allowance of turnips, carrots, or mangold wurtzel made and doled out daily in bad weather. In my experience, rabbits prefer newly-planted trees and shrubs to those established. I have even had the fronds of newly planted *Athyrium Filix femina* eaten, while other ferns have been untouched. There is one hint I may give your rabbit-preserving readers: certain breeds of wild rabbits are much more prone to bark trees than others. The barking of trees is an acquired propensity more common to north-country rabbits than others. I should advise the destruction of those rabbits whose propensity for shrubs is very marked, and try warren or common rabbits from the south of England; but the best advice I can give is to have no rabbits at all. —W. INGRAM, *Belvoir*.

—In your first number you had a list of plants and shrubs, taken from the *Field*, which are said to be proof against the attacks of rabbits. The names of the majority of them were contributed to that paper by me; but I see in the list the laburnum figuring as invulnerable. Now, our experience here is that it is one of the *first to be attacked*, and we have to protect the stems even of large trees; both laburnum and holly, with a coating of lime and cow-dung, or of charcoal. A stitch in time saves one never knows how many, and the knowledge of this may save much disappointment.—HERBERT MAXWELL, *Wigtownshire, N.B.*

French Horticultural Relief Fund.—A meeting will be held at the rooms of the Royal Horticultural Society, South Kensington, on Tuesday, December 18th, at 1.30 p.m., to decide on the distribution of the funds accumulated for this purpose.

Trees in Victoria.—Recent explorations show that the great Australian trees exceed in height, though not in circumference, the giants of California, though some of the Australians must be regarded as very respectable in girth as well as height, the hollow trunk of one of them being large enough to admit three horsemen to enter and turn without dismounting, while they let a fourth horse. A fallen tree, in the recesses of Dandenong, Victoria, was measured ten long since, and found to be 420 feet long; another, on the Black Spur, ten miles from Healesville, measured 450 feet.

THE GARDEN.

"This is an art

Which does mend nature: changes it rather: but
THE ART IS NATURE!"—Shakespeare.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER.

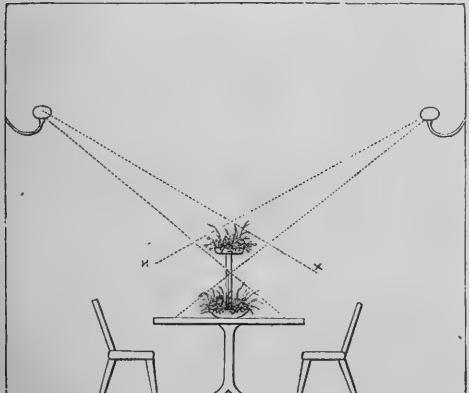

Readers who may find it difficult to procure the numbers regularly through the newsagents or booksellers, may have them sent direct from the office, at 1s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance. "THE GARDEN" is sent to subscribers by Friday evening's post.

THE GARDEN IN THE HOUSE.

ILLUMINATION OF DINING-ROOMS.

MANY may be disposed on first thoughts to regard this subject as more fitting for the columns of the *Builder* than THE GARDEN. And so it might be, if it were my intention to suggest alterations in the mode of lighting. My present object, however, is only to treat of the different methods as I find them, and to show their bearings upon the decorations of dinner-tables. The various ways in which a dining-room can be illuminated may be treated of under the three headings of Table-lights, Ceiling-lights, and Wall-lights. By *Table-lights* I mean all kinds of oil and spirit lamps, candlesticks, candelabra, and gas-lamps supplied by flexible tubes. Upon large dining-tables some of these occasionally look well, while upon small tables they are always in the way, and generally regarded, more or less, as a nuisance, though in many cases a necessary one. Under the heading of *Wall-lights* I would include all kinds of illumination proceeding from, or placed near to, the walls: such as gas-arms and branches, girandoles, and all modes of lighting enumerated under the heading of table-lights, when they are used upon sideboards, shelves, brackets, &c., round the room. By *Ceiling-lights*, I mean chandeliers, gascliers, and sun-burners of various kinds.

Of these modes of lighting I regard table-lights as the

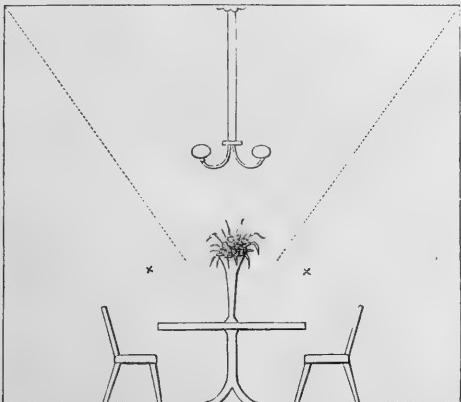

most objectionable when flowers are to form part of the decorations. There is less objection to ceiling-lights than to table-lights, principally because the "machinery" of lighting is more out of the way. But the best of all kinds of lighting is that from the walls, when not placed too far from the ceiling.

The accompanying diagrams will enable me to explain more readily the influence which this mode of illumination should

exercise over the selection of suitable vases. They represent sections of a room fourteen feet wide and twelve feet high, containing a dining-table four feet six inches in width, and of the usual height; two feet four inches. The X indicates the position of the eyes of a person seated at the table.

In the illustration of a room lighted from the walls will be observed dotted lines proceeding from the wall-lamps, and passing above and below the group of flowers in the upper dish of the "March glass." These show that no portion of the shade, caused by the light falling upon the upper dish, comes upon the lower dish, and that both dishes are fully exposed to the light.

In the sectional drawing of a room lighted by a gasclier it will be seen that a trumpet-shaped vase has been introduced

as the centre ornament, instead of a "March glass." This latter form of vase would be quite out of place where the illumination is from above, since everything in its lower dish must then be thrown into deep shade by the decorations in the upper dish.

When rooms are lighted from the ceiling, it is, perhaps, the safest way to restrict one's self principally to flat styles of floral arrangements upon the dinner-table. If I were asked to describe the plan of illumination most suitable for dinners, I should draw a line from the middle of the dining-table to the angle of the room where the wall and ceiling meet (as shown by dotted lines in the sketch of a room lighted from the ceiling), and I should fix the lights at nine feet from the floor where that measurement crosses the dotted line. The number of the lights and their size must, of course, depend upon the length of the room, which is here assumed to be fourteen feet wide.

W. T.

Gleichenia filabellata.—Would not this make a charming plant for table decoration, especially on the interesting occasion of a wedding breakfast? Its branches fork off at different heights into three or four divisions, making nice receptacles for little Cupids, made either of paper or parian. If this hint were taken up by some of professional table-decorators, I am sure the bridesmaids at least, would think the design "sweetly pretty." Happy would I be if I could get a graphical artist to illustrate this matter as Mr. Hole has his Agave telegraphic.—WILLIAM TELLER, Wallington.

Variety in the Leaf Decoration of Flower Vases, &c.—Sometimes the effect of large flowers is spoiled by intermixtures with puny flowers of other plants, or an attempt to *green down* the blaze of colour by fern or other leaves. The proper leaves for many large flowers are their own, or some other large kind. It may be fancy more than correct taste, but it seems to us that even fern fronds are rather out of place with such cut flowers as rhododendrons. We recommend the use of leaves of the same kind as the flowers, or royal ferns, which is applicable to the dressing of flowers as of fruit, though not perhaps to the same extent. He said, "Each fruit should be dressed up garnished with its own leaves." Why not each flower? An attempt to conform to such a law would give more freshness and variety to our floral devices than ought else we could try. What should we think of the ladies if, with all their changes of dresses, they invariably used the same trimmings? To a large extent this is just what we do with our flowers. We get them all alike, and then mix them all alike with the same ferns. Would it not be better taste to let them have their own leaves first? There is no fear of not using enough fern; but distinctness and freshness could often be reached if we laid it aside now and then for other greens. Many of the Conifers form good substitutes, barring the smell when bruised; and asparagus, common grasses, and numbers of other plants, may be used with as good an effect as the ferns.

THE CULTURE OF PLANTS IN ROOMS.

(Continued from p. 84.)

THOSE modes of ventilation by which cold air enters the apartment at once are the most common and the most imperfect. The admission of air in cold weather by the windows is particularly injurious, as it enters the apartment just where the plants are standing. Even the opening of small ventilators in frosty weather must be very cautiously practised, so that a current of cold air may not reach the plants. The ventilators which are pushed outwards are much better than the valve ventilators, as the current of air can be better regulated by them. Still better is it to have a ventilator in the wall of the room under the ceiling, unless the amateur prefers the newly-invented and useful contrivance by which the external air is conducted in a warm condition to the stove. Where gas is employed the ventilation must be in the ceiling, or close under it.

The lighting of the apartment is a matter of no small importance. The use of gas for this purpose is attended with particularly hurtful consequences, as, in the first place, even a very small quantity of gas escaping into the atmosphere of a room will cause the leaves to fall and make the plants sickly; and, in the second place, a number of gas-burners will raise the temperature of a room at night, when it ought to be lower, and moreover will consume an immoderate quantity of oxygen. Where it would be inconvenient to dispense with the use of gas, the pipes and cocks should be well looked to, that they do not allow the least escape. These are seldom found to close perfectly air-tight, and should be promptly replaced or repaired. The use of gutta-percha tubes, such as are commonly employed for conducting the gas to reading-lamps, should be particularly avoided; as these tubes become penetrated by the gas, or, at least, emit a very bad odour. Two or three coatings of varnish or oil-paint will make them more secure, if they must be used. The gas-pipes should be touched with cement in suspicious places, and covered all over with a good coating of oil-paint. When the gas is lighted the cocks should not be turned so as to let out more than is absolutely necessary to feed the flame, or allow the escape of any unconsumed gas. All the cocks should be closely examined, and every one that is not perfectly air-tight should be at once replaced by another. The plants which stand in the windows can be somewhat protected from the glaring light and the increased heat, by means of curtains.

Good ventilation will, in a great degree, obviate the disadvantages which arise from too high temperature and the undue consumption of oxygen, so that with proper attention to this point successful culture is possible, especially when, by the evaporation of water, the air is kept somewhat more humid. These two particulars are the essential conditions of successful culture in rooms which are strongly lighted almost daily and until far into the night.

THE ARRANGEMENT OF PLANTS IN APARTMENTS.—The skilful gardener will easily make such a judicious disposition of plants in a plant-house, that each will have the position best suited for it without prejudice to the other plants, or to the general scheme of the entire arrangement, but any difficulties that may arise here, will be experienced in a much greater degree with plants cultivated in rooms. Of these we shall first consider the most common arrangement, that is, in windows or their immediate proximity. The best and most suitable position is in the window itself. If the window-sill is so narrow that the leaves of the plants are brought into immediate contact with the glass, so that in winter they are exposed to the frost and are in summer liable to be scorched by the sun, then must the window-sill be made broader by the addition of a board. This board should not only overlap the window-sill, but be higher than it by the space of an inch, as in winter the window-sill itself is a colder position for plants than the raised board, between which and the window-sill the warm air of the chamber can circulate. Where it is desirable to have the greatest number of plants in a window, a series of shelves can be placed over each other, at such distances as the height of the plants will permit; but as this arrangement shuts out too much light from the room, and is besides rather unsightly in appearance, it cannot be employed for decorative purposes, but should rather be confined to the double window proper.

The plants placed in the window for ornamental purposes should be so arranged that the leaves of one may not come into contact with those of another, nor with the window. In summer and spring, they should be shaded from hot sunshine by a curtain of thin material inside the windows or by a blind on the outside, or it may suffice to place a board before the pots, so as to shelter them from the direct influence of the sun.

The amateur should commence the room-culture of plants with the determination to grow a few plants into fine specimens, rather than have a great number which, from want of a suitable position and sufficient room, are always puny and pinching away. A few advantageously placed plants in the full beauty of growth and strength will

afford more pleasure to the cultivator than a whole host of mediocre specimens.

In a room plants do not receive light from above and all round, but only on one side. In consequence of this, a more vigorous growth is always going on at the side whereon the light falls. Therefore, in order to obtain well-formed, symmetrical specimens, both sides of the plant should be alternately turned to the light.

When the specimens have in this way been well grown in the window, it will be time to remove them to another position in the vicinity of the window. This is necessary for two reasons: in the first place, because very large specimens in the window would deprive the rest of the plants in the room of too much light; and, in the second place, because the specimens themselves have no longer sufficient room in the window for their own symmetrical growth. The growth of handsome specimens abundantly covered with vigorous and perfect leaves will afford the highest degree of pleasure to the amateur, and will richly indemnify him for his daily care. To this end an uncrowded arrangement of the plants in the immediate vicinity of the window on small tables or stands about the height of the window-sill is the most suitable. The size of the round tops of these stands may be from nine inches to a foot in diameter, so as to be just capable of holding large pots. In drawing-rooms, where the rest of the furniture is of an elegant description, these stands may be tastefully wrought in wood; but equally suitable are those of a simpler kind, which any basket-maker will supply cheaply. I mean those stands supported on four plain legs, which are bound together by interlacing wicker-work, the upper part of the stand being surrounded by a rim or bordering of wicker-work, which serves to shelter and conceal the pots. It will be well to have these stands of various heights, from the height of the window-sill down, as the larger the specimens grow the lower the pots will have to be placed, until at length they rest close to the floor of the apartment. We say close to the floor, because a pot or a tub should not be placed on the floor, as it would injure it; and, besides, in a room which has no regular heating apparatus underneath, a position immediately on the floor would be too cold for plants in the winter. They can be placed on low stools or on inverted pots; or, where a more elegant arrangement is desired, on wooden stands or baskets with feet a few inches high—only, do not allow the pots, tubs, or vases to come into immediate contact with the floor. The basket-maker, the potter, the gardener, and the manufacturer of ornamental garden requisites in iron and wood nowadays vie with each other in producing a vast variety of designs, and offer free scope for the exercise of individual taste in this matter. To sum up, the conditions to be observed are, to choose a position near the window where the plants will receive a full supply of light and to keep the pots raised from immediate contact with the floor.—From the German of Dr. Regel.

THE IN-DOOR GARDEN.

THE SWEET INDIAN DAPHNE.

(DAPHNE INDICA)

THIS is one of those beautiful plants that are often hurt by kindness. Everybody wishes to have it, not less for its appearance when well grown than for the delicious aroma which the flowers exhale. Plant-growers differ as to its cultivation, some considering grafted plants indispensable, while others would rather have the plant upon its own roots. Much, however, of the success which should attend the cultivation of a grafted plant will depend upon the perfect health and vigour of the stock upon which it is worked. Sometimes the common wood spurge (*Daphne laureola*) is used, but we have found *Daphne pontica* form the best stocks. These should be thoroughly established in three or four inch pots, and the grafting may be performed either in the autumn, when the wood of the season is sufficiently firm and ripened, or in the early spring, after the plant has done blooming. In the former case the grafted plants, after having the graft neatly and firmly fixed and the wound made air-tight with a coat of cold grafting wax, should be placed in a cold frame or pit under the protection of a close-fitting bell glass or hard light, keeping the roots sufficiently moist, but not syringing the plants more than once a week, when the glass should be left off until such time as the foliage has got rid of the superfluous moisture. In spring grafting it is advisable that the stocks should be placed in a gentle heat to excite them into growth before they are grafted, and if at the same time the plant from which the

grafts are to be taken can be placed in a similar temperature it will be well, as then the stock and scion will be in the same state of growth, and the chances of success will be much increased. In the hands of an expert workman the grafts need not exceed an inch in length, half to be attached to the stock, and the other half, which may have two or three leaves and buds, being left to form the plant. What is called side grafting, with the head of the plant left on until the graft has taken, is the best, as then the head may be gradually reduced until such time as the whole force of the plant is concentrated on the graft. Of course, plants that have been growing in heat must be kept in heat after they are grafted, giving them the protection of a hand light in a warm pit or forcing-house, until such time as the buds swelling into growth show that the grafts have taken. Then gradually give air, until, in the course of a week or ten days, the young plants, being properly hardened, may be exposed to the atmosphere of the house.

Cuttings of this Daphne are best put in the autumn, when the young wood is something more than half ripe. Small side branches of about an inch long, if they can be procured, form the best cuttings; but if not, then larger pieces may be cut into portions of about an inch each. In preparing the cutting-pot let it be thoroughly well drained; place over the drainage a layer of nice fibrous loam, made quite firm, and over that a thin layer of silver sand. In this the cuttings may be inserted, not too thickly, and then covered with a bell glass. Keep the cutting-pots in a cool, close propagating-pit or frame for a month or six weeks, by which time they should be nicely catised; and if they are then placed in a gentle heat, roots will be immediately formed. It will not, however, be wise to pot the cuttings off until after Christmas, and then, if placed in a close and gentle heat, they will immediately start into vigorous growth.

The secret of growing this charming plant—and it is the only secret in its management—is the fact that it abhors composts and nostrums. Give it good uncultivated loam full of fibre, and it will grow like a willow; nurse it with peat, leaf mould, manure, &c., and, like other over-potted things, it will not grow at all. This may be considered the reason why ill-grown plants are the rule, and well-grown plants the exception. Take a nicely-grown plant with three or four branches in early spring. Place it in a temperature of fifty or sixty degrees; in a fortnight or three weeks it will show indications of growth. Then pick out the point of each shoot, which will cause them to throw duplicate branches, so that you may have eight or twelve of these. When the young branches are about half an inch long, the roots may be examined, and, if in a fit state, the plant may be shifted into a larger pot. In doing this, take care that the pot is properly drained; use the fibrous turf before-mentioned, pot quite firmly, and keep the plants somewhat close until such time as the roots have taken to the fresh soil. The Daphne, in its growing season, delights in a moist, moderately warm atmosphere, and a free circulation of air. If a growth of four to six inches in length can be got by the middle of June, then the shoots may be again stopped and a second growth encouraged. This will add to the size and compactness of the specimen, but its blooming will not be so certain as if the first growth had been allowed to mature itself.

The blooming of this plant centres entirely in the thorough maturation of the wood, and to that end it is much better to rest satisfied with an early growth, than by forcing a second lose the chance of bloom. To insure their blooming, it is necessary that the plants be exposed to full light and a free circulation of air till the end of June; and if after July, when gradually inured, they can be exposed to the full sun and a southern aspect, the certainty of their blooming will be much increased. During the season of active growth the plants, if well rooted, may be assisted with weak manure or soot water once or twice a week; and even in the blooming season an occasional dose of manure water will be of service. The blooming season over, the plants, if not in heat, may be placed in a viney or other forcing house, syringing them lightly, but not giving much water at the root. As soon as the leading shoots show indication of growth, go over the plants, and pick out the point of each branchlet; keep them in the same temperature; and, as the buds begin to break, increase the

supply of water. Should the plants require more pot room, let them have it when the young shoots have just started into growth; keep them in a moist, growing temperature for a few weeks, and then gradually move them to full exposure in the open air as before directed. In this manner, using the soil before described *only*, the Daphne may be grown and flowered as freely as a common pelargonium; but, unless it is distinctly understood that the plant must have a season of growth, maturation, and blooming, success in pots is impossible.

Another simple way to succeed with this very popular subject is to plant it against the back wall of a greenhouse or conservatory, in as light and airy a position as possible, and in the soil above recommended.

A.

BEGONIAS.

THESE are graceful and elegant at all times, but more especially are they desirable during the autumn and winter months, when flowering plants are scarce. True, we have Chrysanthemums in abundance; but, notwithstanding the assistance they lend us in the way of decoration, they are only admissible in conservatory arrangements to a limited extent, while Begonias are more or less overlooked. Although the latter seem to revel in a warm moist temperature during the early stages of growth, a temperature of from 55° to 60° will be found to suit them perfectly during the summer months, giving them the full benefit of sunlight to promote maturation and induce profusion of flowers. It may, however, be necessary to reintroduce to the stove some of the varieties, such as the lovely *B. fuchsoides*, in order to bring them into flower. Nevertheless, it should be borne in mind that when this is not absolutely necessary, it is not a desirable course to pursue in the case of plants that are expected to embellish the conservatory during winter.

For general purposes Begonias should be propagated annually from July all through the autumn months. They will root in about ten days, and may be potted into small pots in a compost of equal parts of loam, leaf-soil, and sand, and kept in a free growing temperature, sprinkling them frequently overhead. In short, they luxuriate in moisture when in active growth. The loam in the compost may be increased in quantity at each successive potting, and a little well-rotted manure may be given when the loam is not of a rich character, but this is seldom necessary. Thus treated they will make rapid growth, and they will be benefited by occasional applications of weak liquid-manure during the autumn to assist their flowering.

The following are the varieties which I grow, viz.:—*B. Chelsonii*, an elegant kind which may well stand in the foremost rank. It is a hybrid between *Boliviensis* and *Sedenii*. It is good in habit, and its bright glossy red flowers are large and attractive. *B. hybrida multiflora*, another of my sorts, a cross between *B. fuchsoides* and *B. parviflora*, has a free style of growth. Plants of it rooted in July 1870 are now six feet in height, and nearly as much in diameter, covered with rosy-pink blossoms suspended on long, slender stems. This is without doubt one of the best sorts we possess. *B. Sedenii*, another garden hybrid, with magenta-coloured flowers, stands a long time in bloom, and is well worth a place in any collection. *B. Dignissima* also ranks among our best varieties. *B. Wiltoniensis* is dwarf in habit, elegant in point of foliage, and a free-flowering kind.

These are among the finest for most purposes, but especially so where variety is considered a desideratum. There are numbers of others, many of which are also well worth attention. For example, there are the tuberous-rooted deciduous kinds, such as *Boliviensis*, a charming plant, with very large bright glossy red flowers, *B. rosacea*, *B. discolor*, and others. These should be gradually dried off in winter, and stored away in precisely the same manner as *Gloxinias*.

When neatly grown, Begonias make useful adornments for the dinner-table, and those possessing a drooping habit are admirably adapted for suspended basket-work. They are valuable, too, for window-decoration, and several of them, such as *floridula*, *Wiltoniensis*, &c., do well when bedded out. They flower freely, and are very desirable in mixed arrangements.

Witley Court.

GEO. WESTLAND.

Single and Double Chinese Primroses in Winter.—Take care of the crowns of these, and the leaves and flowers will take care of themselves. No drip must hit the eye of growth. Though dull, sunless winter is their summer, nothing is easier than to keep their crowns dry, and to have them beautifully in flower when we most want them. Water under—not over—the leaves, and see that the water never floods the axils of the lowermost ones. The roots are greedy of water, and must not be stinted; as the season advances, and

the new year's sun acquires power, they may need two or three drinks a day. But at all seasons keep the leaves dry, especially in the dead of winter. The single varieties suffer more from water on the head than the double sorts. Their leaves are larger and more succulent, and their mode of growth is somewhat different. The double sorts have smaller crowns, and more of them. The most effective single plants have but one crown, deeper and more easily hurt. But, the safest course is not to wet a single leaf of any of them. Few things vex one more than to see the glorious bunches of flowers and foliage of these fine plants suddenly damp-off. With careful watering and judicious ventilation, however, this may be wholly avoided. Next to keeping water out of the crowns, dry them, after watering, with a current of air as speedily as possible; and should perverse, artful drip choose the eye of a primrose as its mark, move the plant instantly and place it beyond the reach of such mischief.—D. T. F.

ANECTOCHILUS CULTURE.

THESE small but exquisite plants rank amongst the most precious jewels of the vegetable kingdom, and few can without the deepest admiration behold the delicate tracery and inimitable markings of their leaves, where the gem-like hues seem to vie with each other in producing the most charming effects of liquid colour. The great object of the cultivator should be the production of fine foliage, and the development of the fine gold and silver veins which are so characteristic of this genus. The only way to accomplish this is to take advantage of the growing season, and to encourage by every possible means a strong, vigorous, and rapid growth. They are not like some plants, which will grow from a foot to a yard in one season, and soon become unwieldy and unmanageable by reason of their bulk. Anectochilus are small, compact-growing plants, averaging from two to five inches in height; and it is simply impossible to grow them too large, provided this is not accomplished at the expense of an enfeebled constitution. Some have indulged their plants with bottom heat, thinking that by so doing they would have increased root action, and consequently more vigorous growth. But this has proved a mistake. The plants have progressed favourably for a time, but the excitement has induced weakness of constitution, and death has been the result in many instances. The pots in which they grow being generally small, the compost in them is sure to be of the same average temperature as the air of the house in which they stand, and this is found by experience to be all that is required in the way of root warmth or bottom heat. Shade they must have; to stand them in the sun is simply folly. The bright glare of light will soon marr all their beauty and stop their growth, even if it does not kill them altogether. In their native habitats they grow in forests under the shade of trees, where none of the direct rays of the sun can reach them. These conditions must be observed and continued, or all our efforts will be in vain. Bearing this in mind, look round the house or stove, and select a spot where the rays of the sun never penetrate—at least during the greater part of the day. An easterly aspect, with a point or two to the north, I have found to be the best for them, where the first gentle beams of the rising sun call forth the active energies of vegetable life. But by the time the sun has been up an hour or two it acquires too much power to allow it to shine upon the beautiful leaves of these delicate plants. Consequently, if the structure does not of itself afford the means of breaking the force of its rays, the *desirous* cultivator will soon discover some means of *achieving* it by artificial means; and here there must be a word of caution. The place they occupy must *not* be a dark corner. They want light, but it must be a subdued light, softened and toned down, and adapted to the delicate structure of the plants. Comparative stillness in the atmosphere is another essential to their well-being and well-doing. The open, airy condition of a house in which other plants are grown will not answer for Anectochilus. Growing as they do in the forest, all currents of air are broken by the surrounding trees; and the plants being of such diminutive size, the coarser kinds of vegetation, grasses, &c., effectually shelter them from anything like a draught. Nestling as they do low down, near to the surface of the soil, the little world in which they live is one of unbroken calm and quiet. To imitate this it is found necessary to cover the plants growing in our houses with bell glasses, or, what is still better, a small box or frame with a glass top,

This should be about two feet or two feet six inches from back to front, and a yard in length. It is better to increase the number than the size of the boxes. Eight inches deep in front and twelve at the back will be very useful and satisfactory proportions. These boxes should never be shut close. It is a good plan to have ribs nailed on the under side of the sheet or cover, to prevent it fitting close to the box or frame. And then a gentle current of air will at all times be passing over the top of the plants, not through or among them, and thus as nearly as possible imitate their natural conditions. If shut close and the atmosphere becomes stagnant, they are almost sure to damp off.

They do not seem to be very particular about the kind of soil they have to grow in. I have grown them in rough, lumpy peat alone, and in this they sent down their roots and did very well. I have also grown them in chopped sphagnum mixed with sand; but this did not seem to afford them sufficient nutriment, so I adopted a compost between these two extremes. Peat is the principal ingredient, but a little leaf mould is advantageous, as it enriches the compost without making it rank: say, as a guide, two parts peat and one part leaf mould, with silver sand equal in bulk to the other two. Then, in addition to this, I add pounded sandstone, made about the size of peas. It is astonishing how the roots will cling to these pieces of soft stone, which absorb moisture and help to keep the soil in a uniform state of dampness, and at the same time secure a free passage for the escape of superfluous water.

Drainage must be on the most ample scale; anything like stagnation is ruin and death. If the compost becomes in the least sour, it is vain to look for success. These plants do not root deeply, therefore it is not necessary to have a great depth of soil. This affords opportunity for securing a very considerable amount of drainage. The pots should be quite clean, well washed inside and out, and then half filled with crocks, the rougher ones being placed at the bottom, and the finer ones on the surface. A little moss on the top of these will prevent the compost finding its way down and blocking up the drainage. If this is carefully and properly done, the pots may be filled with the compost, and little fear need be entertained of its becoming waterlogged. But in addition to this the pots should stand upon two or three inches of pebbles, or some other open material, so that the water can soon get away, and at the same time this material being thoroughly wet, it will constantly and gradually give off moisture to the air in the case.

The pots being prepared as above, the creeping stems of the Anectochilus should be laid upon the surface. If there are any roots proper, they may be left into the compost a little; but by no means bury the stem. This naturally runs upon the surface of the soil, and the growing plant stands erect, showing its beautiful foliage and developing its tiny flowers. To bury these stems is a sure way to bring on decay; while on the other hand to leave them exposed is to get them consolidated, hardened, and ripened, and thus they are enabled to bear the application of water throughout the year, more especially so during the dark days of winter. If these precautions are attended to, water may be freely given without the slightest fear, especially during the growing season, from the end of March to the beginning of October; they revel in a full supply. They may be freely watered overhead with a very fine rose-can or a syringe every afternoon, with water about milk warm. Don't fear wetting the leaves or the stems; they delight in plenty of water, and it is a mistake to keep them merely damp only; it leads to weakness and feebleness of constitution, and causes many to pine away and die. Even during the winter season they must not be allowed to get dry, and a good sprinkling overhead occasionally at that season of the year will be beneficial to them. It cleanses them of dirt, dislodges insects, refreshes the plants, and adds to their health and vigour. It is necessary, however, to be cautious that there be no sediment in the water, otherwise it will leave a stain upon the foliage and disfigure the plants. The flowers they produce are very inconspicuous and unattractive, and as they help to exhaust the plants, it is better to remove the flower-stems as soon as they make their appearance. By this means additional vigour is thrown into the foliage. Being natives of Borneo, Java, and other hot parts of the globe, they require a high temperature to grow them well.

—indeed, I may say to grow them at all; and unless there is the convenience of a stove, it is useless to attempt it. Fifty degrees may be set down as the minimum, and 65° or 70° on a sunny day as the maximum, during the winter months. But through the summer, while they are growing, they may have 65° or 70° through the night, with a rise up to 85° or even 90° in the daytime. This, with the directions given in this paper, will grow them to the greatest perfection; and those who have them will have the pleasure of looking upon the richest markings and most glorious tints of colour that are to be found in leaves.

The Gardens, Didsbury, near Manchester. Thos. Jones.

A CHRISTMAS VASE.

ONE of the most effective vases with which we are acquainted was arranged as shown in the accompanying illustration. In the centre was a good plant of *Epiphyllum truncatum*, surrounded by a ring of large houseleek (*Sempervivum tabuleiforme*) alternated with the common *Pteris serrulata*. We did not see the vase till the *Epiphyllum* had passed out of flower, but even then the effect was very pretty.

Plants of the *Epiphyllum* trained as low pyramids are peculiarly suitable for vase decoration—indeed, it is doubtful if anything that blooms in summer would form so lovely a subject for a sitting-room or conservatory vase as this, which blooms so freely in mid-winter. We had the pleasure of seeing it in Mr. Flowers' handsome conservatory at Furzedown, Streatham, which is usually so well arranged by his gardener, Mr. Laing, and where our sketch was taken.

PALMS FOR THE GARDEN.

(Continued from page 73.)

BACTRIS FLAVISPINA (Brazil).—Fronds from four to six feet long, irregularly pinnate; petiole furnished with yellowish sharp spines, and there are small ones on the margin of the pinnae; erect, dark green. All the species of this genus are dwarf, forming bushes by pushing up shoots from the base; they are fond of heat and water. Though ornamental when young, when old they get lax, and are apt to scratch everything with which they may be associated, thus unfitting them for many purposes to which palms are applied. Many species of *Bactris* enumerated in books are not yet introduced.

B. baculifera, *liboniana*, and *setosa*.—For purposes of decoration these are not better than *flavispina*.

B. maraja (Brazil).—Fronds, two feet broad, abrupt; throws up shoots from the base. This, the best and most compact of the species; runs up with a slender stem, which, however, may be cut down when too high, when a young stem will take its place; must have plenty of heat.

Bentinekia coddapanna (India).—Plant, smooth, pale green; fronds pinnate, spreading; petiole, round; stiff in habit, and a bad grower. *Calamus*.—A very extensive genus, consisting of from eighty to ninety species.

Daemonerops, forty species.

These two genera having got much mixed together in gardens, and their decorative character being similar, I shall speak of them together, denoting the species that belong to *Daemonerops* by the letter D. The only difference between the two consists in the flower spathe of *Calamus* being persistent and that of *Daemonerops* deciduous. The albumen in *Daemonerops* is ruminated; while that in *Calamus* is not—points valueless as far as purposes of decoration are concerned; but they may serve as a test in the case of imported seeds. Both genera are fond of heat and water, and, in a young state, many of the species possess a charming, light, feathery habit, which makes them universal favourites. Though many of them grow more than a hundred feet in height, and become rough in appearance, a few are dwarf, and remain suitable for ordinary purposes of decoration for years. If watered freely, they may be kept in small pots.

C. australis (Fitroy River).—Plant, erect; stem, slender; frond, one foot long; pinnae, three inches; spines, pale brown, fine. All the species have three veins on each of the pinnae, the outer two being furnished with small spines on the upper side. This, the smallest of the genus, grows only from four to five feet high; and, being very graceful in habit, is suitable for a small house or Wardian case. Altogether an elegant palm, and one which has the advantage of being harder than the other species.

C. D. accidens (Java).—Fronds, spreading, dark green; leaf-stalk, brown; spines, irregular. In a young state this is a beautiful plant for stove decoration, possessing, as it does, an elegant plume of foliage.

(To be continued.)

J. CROUCHER.

THE FLOWER-GARDEN.

HARDY TREES IN THE "SUBTROPICAL" GARDEN.

We wish particularly to call attention to the fine effects which may be secured, from the simplest and most easily obtained materials, by using some of our hardy trees and shrubs in the picturesque garden. Our object generally is to secure large and handsome types of leaves; and for this purpose we usually place in the open air young plants of exotic

Atlantis and Cannas.

trees, taking them in again in autumn; and, perhaps, as we never see them but in a diminutive state, we often forget that, when branched into a large head in their native countries, they are not a whit more remarkable in point of foliage than very many of the trees of our pleasure-grounds.

Thus, if the well-known *Paulownia imperialis* were too tender to stand our winters, and if we were accustomed to see it only in a young and simple-stemmed condition and with large leaves, we should doubtless plant it out every summer as we do the *Ferdinandia*. There is no occasion whatever to resort to exotic subjects while we can so easily obtain fine hardy plants—which, moreover, may be grown by anybody and everywhere. By annually cutting down young plants of various hardy trees and shrubs, and letting them make a clean, simple-stemmed growth every year, we will, as a rule, obtain finer effects than can be got from tender ones. The *Aitansia*, for example, treated in this way gives us as fine a type of pinnate leaf as can be desired. Nobody need place *Astrapea Wallichii* in the open air, so long as a simple-stemmed young plant of the *Paulownia* makes such a column of magnificent leaves.

The delicately-cut leaves of the *Gleditschias*, borne on strong young stems, would be as pretty as those of any fern; and so in the case of various other hardy trees and shrubs. Persons in the coldest and least favourable parts of the country need not doubt of being able to obtain as fine types of foliage as they can desire, by selecting a dozen kinds of hardy trees, and treating them in this way. What may be done it this way, in one case, is shown in the foregoing illustration, representing a young plant of *Aitansia*, with its current year's shoot and leaves, standing gracefully in the midst of a bed of *Cannas*.

FAGRANT FLOWERS.

WHAT is a garden without these? Yet we have seen hundreds of gardens without a single sweet-breathing flower except the rose. But even the ever-satisfying and popular rose does not receive half the attention that it ought, in consequence of the all-absorbing attention required for geraniums, calceolarias, verbenas, &c., which are scentless; not remarkable for great individual beauty of flower, like lilies or irises; devoid of any pleasing association, and perishing during the first frost that comes in autumn. We therefore propose to indicate the various ways in which numbers of sweet-smelling hardy flowers may be grown without interfering with the arrangements for "bedding-out plants."

Supposing a little bed or two to be devoted to pinks, carnations, &c., on a warm border in the vegetable department, or anywhere else away from the flower-garden proper, there are not a few other things which might be advantageously associated with them, and among these none more conspicuous than the rather numerous kinds of German stocks, so sweetly scented and so varied; while near at hand might be beds of violets of various kinds, and also a collection of everlasting and ornamental grasses, not to mention other little specialties of that sort; and the whole might be arranged so as to prove a source of ceaseless interest to the lover of a garden. However, enough of suggestion; let us at once proceed with our enumeration of such sweet-scented flowers as we can obtain cheaply, and grow in the open air.

To begin with an annual flower, the finest of all, perhaps, not only in point of perfume, but in point of size and exquisite delicacy of colour, is a species of *Datura*, *D. ceratocalon*. It grows a couple of feet high or more when well tended, and has flowers of enormous size and of a divine sweetness, especially in the evenings, when the large blossoms open after the fashion of the evening primrose. Sow in gentle heat in March or April, and plant out in rich soil in May; if possible, in an isolated spot, so that the plant may not be found what is called an "eyesore" among the bedding plants, for it closes during the day, and looks remarkably like the common thorn-apple when in that state. With it might be associated other sweet plants, such as the mignonette; the new annual night-scented stock (*Matthiola bicornis*); the large, fragrant, and showy yellow *Cnethera Lamarckiana*, very fine and sweet; and particularly so in the evenings, when people most enjoy the garden during hot weather. *Cnethera odorata*, stocks, sweet peas, musk, if you like it, in tufts round the edge, clove carnations, &c. Of such goodly-sized bed a charming feature might be made in some quiet nook; and charming indeed it would prove on the summer evenings, between fragrant flowers and those that open in the evening and close as the rising sun laps up the crystal drops of dew that bead round

the margin of their petals during the nights. Wallflowers, too, might be represented, and fragrant shrubs, such as sweet gale, lavender, &c., might be used; in fact, any person who endeavours to glance through the sweetly-smelling host, from roses to rosemary, and from primroses and cowslips to the Persian lilac and the sweetbriar, cannot fail to remember suitable things to form such an arrangement with. The beautiful snowy-white and cheap *Lilium longiflorum* is also worth growing for its exquisite sweetness alone; and on all fair, light garden soils it appears to us about as easily grown as a potato.

Whatever may be selected, do not forget the mixed kinds of polyanthus, which are so very sweet, and even beautiful in point of colour, for the spring garden. They may be raised from seed in abundance. The sweet Alyssum, low white sweet candytuft (*Iberis odorata*), the fragrant honesty (a biennial), the night-scented stock (*Matthiola tristis*), all come from the same order as the wallflowers, and are worthy of remembrance in a collection of this sort. Sweet sultans, too, with the Moldavian balm, sweet but not showy; the balm of Gillead (*Dracocephalum canariense*), peculiar, best fitted for the greenhouse in winter, though it will grow well against a wall in summer; and the common balm of the herb ground, which is to us always a pleasing perfume, are all worth growing. Not a few people gather lavender for homely perfumery; indeed, we have never seen this done to such an extent in any garden as in those at Frogmore, for her Majesty's use; but there is a sweet little herb equally well adapted for such purposes, which is not at all so much used as it ought to be, and that is the little British woodruff (*Asperula odorata*), which is so common in many woods, its green mass of leaves powdered over with small white flowers. It grows as freely as grass in any shady spot of the garden, or indeed anywhere, and should be pulled and left to dry in a drawer. The leaves furnish the fragrance. When growing or culled they do not smell, but a few hours afterwards the aroma begins to develop itself; the dried foliage and stems of this little herb retain their sweetness for years in a drawer.

As to hardy shrubs and things of that kind, the common jasmine—common, but unsurpassed for sweetness—flourishes anywhere on a wall, and is entitled to the gratitude of all for being obliging enough to flourish in the very heart of all our great wildernesses of bricks, even down in the areas and the backyards of those parts of our cities where the truth of Cowper's line, that "God made the country and man made the town," is forced upon us in all its reality. Another climbing shrub of priceless value, and perfectly hardy and cheap, is *Clematis Flammula*, which makes the garden or the grove as sweet in the golden days of autumn, and rather late on towards winter, as the hawthorn does in spring. Employ it as a trellis plant, or in any position where you would employ a climber; but to thoroughly enjoy it, plant it in your shrubbery, near some old stump of a tree, some old specimen that was cut down; or anything that it can crawl over, and then it will give no trouble, but the highest satisfaction. It is very useful for cutting for in-door decoration, and a few sprays of the flowers among the autumnal blooming roses (now so common) look very well, as they do indeed in any group of cut flowers. Then there is the early spring-flowering *Daphne Mezereum*, the low and charmingly-coloured *D. Oneuron*; the extremely disagreeable, when broken, but deliciously sweet-flowered spurge laurel; not to mention the bay, the various kinds of lilac, and the myrtles and sweet verbena, which make large shrubs in the south of England and Ireland; the great flowered American *Magnolia*, the fragrance of which is as powerful as its flowers are large and nobly formed. In the south this plant makes a fine plant for walls, as indeed it does on favourable soils in the midland counties of England and Ireland. At Bicton there was a wall of this which, previous to the scathing frost of 1860, used to scent the whole place; and though the plant does get cut down now and then in very hard winters, it is well worth planting again, if indeed that be required, for the old plants shoot up afresh. Then there is another fine wall shrub to which far more attention should be directed than has yet been the case. We allude to the deliciously sweet *Chimonanthus grandiflorus* the most worthy of all shrubs to be placed in a warm corner against a wall, let that belong to terrace, house, outhouse, or cottage. It has the distinguishing peculiarity of flowering in

winter, when sweet flowers are scarce; and a few sprigs of it, gathered and placed in a vase of flowers in the drawing-room, distil an almost matchless odour without being observed by those who know not the plant; for the flowers, though not small, are singularly inconspicuous. Finally, do not forget our old friend the winter heliotrope (*Tussilago fragrans*) which flowers so sweetly about Christmas, and may be culled for mixing among cut flowers at that period, its unobtrusive blossoms scenting the room. But do not admit it into the garden, or it may become a contumacious weed. Some "out-of-the-way place" is its home. An old lane, bank of rubbish, hedge bank, or any such wild or half-wild spot, will suit it to perfection; and, besides, the wild latitude it will have to run about in, will insure a plentiful supply of flowers, which could not be had from a small garden patch.

V. E. R.

PINKS, CARNATIONS, AND PICOTEES.

It was perhaps no wonder that, before the glare of colour which adapted itself to the wants of those who had but little taste in gardening, a great number of second-rate plants were driven out from cultivation and forgotten; but that such richly-coloured, often elegantly-laced and tinted, and always gratefully odorous subjects as picotees, carnations, and pinks, should almost disappear from cultivation under its auspices, is truly a marvel. Here we have a rare combination—beauty of colour, dwarfness and neatness of habit, perfect hardiness, capability of growing in almost any soil and in any part of the country, aromatic and delightful fragrance, and, in a word, the highest beauties of any flowers we know. And yet what is the practice? Why, there are many gardens where such a bunch of the clove carnation, or common pink as you may buy in London for a mere trifle from the flower-hawkers could not be culled. Now there is no reason whatever why we should not have a moderate and tasteful display of what is called "bedding-out," and enjoy the peerless beauty and grateful fragrance of this fine tribe of hardy and essentially English flowers. There is no reason whatever why we should sacrifice all beauty and interest to the display of a few things which merely attract by their colour, but produce such a monotony in gardens generally, that we are quite surprised that educated people do not cease to take an interest in gardens at all. Why not have your beds of carnations richly striped and fine in form, your elegant picotees laced with the most refined elegance of colour, and your sweet and abundantly blooming pinks, from the common pink of the London flower market to large and rich Anna Boleyn? Suppose you cannot, in your narrowness of heart, afford them a bed in the flower-garden, why not devote a few yards of a snug border in the kitchen-garden to them, even if there be no space wherewith to put them round the borders? For their value for cutting alone, for bouquet making, and in-door floral decorations, these flowers would be well worth cultivating, even if they had not attractions enough to entice anybody with a particle of love for flowers to their quarters to see them open their beautiful petals. We know one large place in which the demand for cut flowers is very great, and it is well met by devoting a portion of ground in the reserve garden to pinks and carnations; they supply a great want, and are cut in quantity. Great is the amount of variety in the three sections, and many of the charms that may be added to a garden by a selection of the best of each. Each may be raised from seed without much trouble, though of course in that way you cannot expect to get the choice varieties which you may obtain by buying young plants of a nurseryman.

V.

Golden-Edged Lemon Thyme.—(*Thymus citriodorus aureo marginatus*.)—This golden-edged variety of the old lemon thyme is about as superior to the so-called silver variegated form of the common thyme as genuine claret is to gooseberry wine. In habit it is equally dwarf, dense, and compact as our old familiar garden favourite, and it retains its variegation so perfectly and evenly distributed, that out of some thousands of plants not a single one showed any tendency to revert to the normal state, nor was a green leaf to be seen. As a variegated plant it possesses these qualities: a deep green and bright shining leaf, which contrasts with and sets off to the best advantage its golden variegation, the latter monopolising fully one half of the leaf's surface. In fact, I can compare it to nothing but

a perfect miniature of the lovely variegated *Coprosma*, which will soon claim high rank amongst bedding plants. What a charming marginal zone it will make by itself! or, perhaps, better still, alternated in tufts with the denser forms of the *Aubrieta*, whose purplish-blue flowers would contrast—each borrowing intensity from its neighbour—as markedly as the habit of the two would be in harmony and accord! Add, if you like, an interior circle of *Altemanthera*, and thus complete a girdle of beauty such as even Flora herself might rejoice to wear. No flourish of trumpets has announced its advent, but quietly and unobtrusively will it take its well-defined position in the flower garden, and I am no prophet if it does not keep the same through a long series of years. Everyone to whom I have shown the plant gives utterance to but one exclamation—charming!—JAS. C. NIVEN, Botanic Gardens, Hull.

NOTES AND QUESTIONS ON FLOWER-GARDENING.

Crocus-Ground.—What is best to do with a recently turfed crocus-ground, and on a sandy subsoil?—B.R.A.—[Top dress with half-inch finely sifted fresh loam, and sow with a mixture of good grass-seeds suitable for light soil.]

The Maiden-Hair Meadow Rue.—Can I find this charming plant wild? and how shall I treat it?—S.—[*Hedlundium minus* is abundant in various parts of the country, but in many districts you will find it easier to obtain plants from nurseries. As to treatment, it only requires to be planted. The wild plants should be taken up carefully, and must be well established, and not disturbed, before they show their full beauty.]

Millettia.—I have seen a specimen of this (p. 50) it is said, "In the open air we have not noticed it in flower in this country." I have seen it here both in flower and seed more than once. But to produce flowers, it is not the right course with the plant to treat it as a hardy herbaceous one. It must not be cut down, for the flowers are produced on the wood of last year. In mild winters its fine foliage is very striking; nor do I agree that its bloom is not ornamental. As a large, well-grown plant it is certainly ornamental, and the flowers are very sweet.—HENRY W. ELLACARRE, Bitton Vicarage, Gloucestershire.

Moss on Lawns.—Will you kindly tell me how to remove moss from my lawn? It almost destroys the grass.—R. H., Portman.—It is better not to disturb it in the early spring, as even the most violent treatment will do a ministerial damage. If you take a top-dress of the ground with long-toothed rakes; and this should be done twice, allowing an interval of a week to elapse between the raking. In the early part of March the ground should be dressed with fine rich loam, with about a sixth part of lime added. It should be fine, so as to save the trouble of stone-picking, and then sow with a mixture of fine lawn grasses. If lime is cheap in your neighbourhood, give the lawn a liberal dressing of it as soon as you may venture to disfigure it in the autumn. That may do without the raking up.]

The Mole Tree.—The Copper Spurge (*Euphorbia Lathyris*) is known as the mole tree in parts of Pennsylvania from a popular notion that it keeps moles out of gardens. Those of our readers who have sufficient faith may perhaps feel inclined to try the experiment. A yet more remarkable protector of gardens is found in *Canavalia gladiata*, a twining leguminous plant, which, according to Dr. MacFadyen, is called "Overlook" by the negroes of Jamaica, who plant it along their provision-grounds, from a superstitious notion that it fulfills the part of a watchman, and, from some mysterious power ascribed to it, prevents the thefts of their plunder. Even this belief may influence the practice, although they themselves may not place confidence in any particular influence which the plant can exercise, either in preventing theft or in punishing them when committed.—B.

Sub-Tropical Plants Without Glass.—I have little or no glass, but should like some of these in my garden. Can I get a frame or small pit, if necessary. AN AMATEUR, Torquay, Devon.—[Your best plan will be, to select all the beautiful hardy plants of picturesque habit which you can get, such as the Bamboo, Pampas Grass, Yuccas, &c. These, with graceful young conifers, &c., will go far to give a picture-like effect to your garden. You will also want several delicate trees without them, you could grow *Ganna*, perhaps the most valuable of all fine-leaved flower-garden plants. Some, like the Castor-oil plant, may be raised in a warm pit or frame, and some plants of much value, when properly placed in the flower-garden, may be raised with hardy and half-hardy annuals. Among these may be named *Artemisia annua* and the common hempe.]

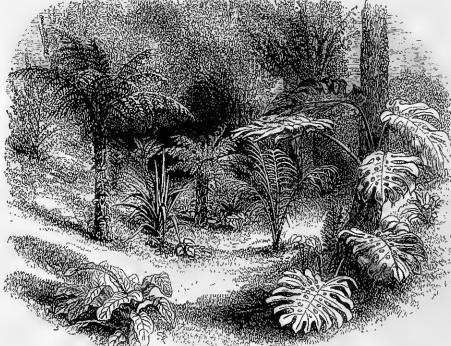

Tall Border Plants.—Can you furnish me with the names of a few plants of this description which would look well in front of shrubberies, or at the back of mixed borders?—A. S.—[*Acmonia sternbergiana*; *A. variifolia*; *Daphne gnidium*; tall varieties; *Baptisia exaltata*; *Lathyrus latifolius*; *L. latifolius albus*; *L. grandiflorus*; *Entothroa Lamariacea*; (*E. Jamesii*); *Epilobium angustifolium*, *E. a. album*; *Lithrum Salicaria rosea*; *Echinops exaltatus*; *E. ruthenicus*; *Galega officinalis*; *G. o. alba*; *Aster Novae-Angliae*; *A. Novi-Belgii*, a elegans; *A. ericoides*, and many others; *Achillea Eupatorium*; *Campanula latifolia*; *C. pyramidalis*; *Asclepias Cornuta*; *Verbascum Chaixii*; *Phlomis*; *Polygonum perfoliatum*; *Polygonum* in variety; *Dianthus barbatus*; *Lilium tigrinum*; *Fortunei*; *Polygonum* in variety; *Anemone*; *Douglasii*; *Pampas grass*; *Anchusa italicica*; *Arundo conspicua*; *Eupatorium ageratum*; *E. purpureum*; *Helianthus argyralis*; *H. multiflorus*; *H. speciosus*; *H. annuus*; *H. tuberosus*; *H. miltaris*; *Chrysanthemums*; *Dahlias*; *Pyrrethrum uliginosum*; *Crambe cordifolia*; *Phytolacca decandria*; *Lupinus polyphyllus*; and *Macleaya cordata*

Yuccas.—Perhaps no class of hardy plants deserve more encouragement than *Yuccas*, of which several very interesting species are now growing in English gardens, viz., *Yucca gloriosa*, *revoluta*, *superba*, *filamentosa*, *filamentacea*. Notwithstanding the stately habits of these plants, it is surprising to find them not more generally cultivated. *Yuccas* are plants of easy propagation, and advantage should be taken of this circumstance to have them more generally diffused. They succeed best in a rich, loamy soil, and, when in flower, amply repay any trouble taken to bring them to maturity. A good flowering spike, independent of its leafy stem, often attains the height of four or five feet, and measures from three to four feet in circumference, each spike producing several hundred cream-coloured star-shaped blooms. After flowering, the stems of the large varieties generally divide into two or more leaders, and, if well cared for, a succession of flower-spikes will in time be produced

from them, the strongest stem flowering first. In Scottish gardens, the variety most commonly grown is *Y. gloriosa*; but in Ireland, more particularly near Dublin, *Y. recurva* appears to be most prevalent, and it is, without exception, the most graceful of the two. The effect of this variety in Merrion Square, Dublin, is quite remarkable. Their prevalence in that locality is due to the energetic efforts of Mr. Adair, who has done much to extend the cultivation of many new and half hardy plants in Ireland. Although *Y. superba* and *recurva* are most abundant near London, yet a large proportion of *Y. gloriosa* is also to be met with, while *fascicula* and *filamentosa* are common both in the London gardens and throughout the country, both species being frequently found under the same name. *Yucca* may be considered by many as rather stiff and formal in habit; but a method of growing them which does not take off the stiff appearance, while it preserves their original character and outline, has recently been adopted here. This method is to grow them in raised stone compartments, or in rustic stone stumps, as we call them, a description of which will be found at pp. 70, 71 (No. 4) of THE GARDEN. It is desirable that the soil should be made good considerably below the base of the stones, so as to induce the roots to go down. It will be found that the roots of the *Yucca* take freely to the stone, and that the stems will be well supported. The rockery cultivation of *Yuccas* is intended to stand on extensive rockworks or grass lawns. Their effect on grass lawns is considerably improved by having them raised on circular rockwork mounds standing two or three feet above the surface. This raised portion should be formed into rockwork compartments, and filled with dwarf Alpine, or with such plants as *sedums*, *sempervivums*, and *saxifrages*, the spaces between the buttresses being admirably adapted for them.—*J. McNab, in "Villa Gardener."*

A TROPICAL DELL IN THE GARDEN.

ONE of the boldest and most charming little pictures formed by Mr. Gibson, when superintendent of Battersea Park, was the placing in a shady and thoroughly sheltered nook stove and greenhouse plants and ferns that will not suffer from exposure to our summer climate. The plan, so happily shown in our illustration, is well worthy of imitation in the southern and milder parts of the country. Our illustration shows a scene somewhat more free in its disposition than, Mr. Gibson's admired nook at Battersea.

Shady and sheltered Dell, with Tree Ferns and other Stove Plants placed out for the Summer.

Some palms, like *Seaforthia*, may be used with the best effect for the winter decoration of the conservatory, and be placed out with a good result, and without danger, in the summer. Many fine kinds of *Dracaenas*, *Agaves*, *Yuccas*, &c., which have been seen to some perfection at our shows of late, are eminently adapted for standing out in summer, and are in fact benefited by it. Among the noblest ornaments of a good conservatory are the Norfolk Island and other tender *Araucarias*; and these may be placed out for the summer, much to their advantage, because the rains will thoroughly clean and freshen them for winter storing. So with some Cycads and other plants of distinct habit—the very things best fitted to add to the attractions of such a nook as the above. Besides, there are tall hardy ferns, and other picturesque hardy plants with a tropical aspect, which might be planted out in such a dell. They would make the furnishing of it an easier matter. In fact, there is no moderately-large gardening establishment which ought not, between tender and hardy plants, to embellish such a dell in the most graceful manner. There are, however, many districts in which it would be unwise to place the stove plants in the open air; and even in the warmest, it would be necessary to secure the most perfect shelter and as warm a position as possible.

THE WILD-GARDEN.

DITCHES, NARROW SHADY LANES, ETC.

MEN usually seek sunny and favourable positions for their gardens, so that even those who are obliged to be contented with the north side of the hill would consider my present fancy (the ditch) the whim of a lunatic. What, the gloomy and weedy dyke as a garden! Yes, there are thousands of ditches in every county in England that may readily be made more beautiful than the most finished and expensive "modern flower-garden." But what would grow in them? Many of the most beautiful wood and shade loving plants of our own and similar latitudes—things that love not the open sunny hillsides or wide plains of grass, but take shelter in the stillness of deep woods, hide in dark valleys, are happy deep between riven rocks, and gaily occupy the little dark caves beneath the great boulders on many a horror-stricken mountain gorge, and which garland with inimitable grace the vast flanks of rock that guard the dark or noisy course of the rivers on their paths through the hills. And as these dark walls, ruined by ceaseless pulses of wintry tide, are beautiful exceedingly, how much more may we make all the shady dykes and narrow lanes that occur everywhere! For while the nymph-gardener of the ditch may depend for her novelties on the stray grains of seeds brought in the moss by the robin when building her nest, and the nymph-gardener of the river wall on the mercy of the hurrying wave, we may place side by side the snowy white wood lily (*Trillium grandiflorum*), whose home is in the lonely shades of the American woods, with the twin flower of Scotland and northern Europe, and find both thrive on the same spot in happy companionship. And so in innumerable instances. And not only may we be assured of numbers of the most beautiful plants of other countries thriving in deep ditches and in like positions, but also that not a few of them, like the white wood lily, will thrive much better in them than in any position in garden borders. This plant, when in perfection, has a flower as fair as any white lily, while it is seldom a foot high; but, in consequence of being a shade-loving and wood plant, it usually perishes in the ordinary garden bed or border, while in a shady dyke or any like position it will be found to thrive as well as in its native woods; and if in deep, free, sandy, or vegetable soil, to grow into specimens not surpassed in loveliness by anything seen in our stoves or greenhouses.

The following is a large selection of hardy plants well suited for the positions above named. Very considerable difference is among them as regards size; the stronger-growing subjects will take care of themselves among the scrub at the top of lane and ditch banks:—

INSECTS, BIRDS, ETC.

THE MOLE-CRICKET.

(GRYLLOTALPA VULGARIS.)

This insect has the reputation of doing much damage to various roots. It is, however, certain that it is not wholly a vegetable feeder; some say not chiefly one. It eats, and no doubt benefits the gardener by eating, many grubs and worms; but the balance seems to be on the side of injury rather than good. Curtis states that in the south of France farmers and gardeners complain of the damage done to their crops of peas and beans by these crickets, and that in Germany they have been known to destroy one-sixth, and even one-fourth, of a crop of young corn by eating off the roots. He quotes Mr. Brackenridge to the effect that the mole-cricket is the greatest enemy the gardener has to contend with at Berlin, where it appears about the beginning of summer in myriads, and nothing in the herbaceous way is proof against its ravages, adding that he (Mr. Brackenridge) had seen the stem of a Dahlia an inch thick cut through by it in the course of a night with as much precision as if done by a knife. He further mentions that in the Botanic Garden there the devastations of these insects are so extensive that duplicates of the more tender and uncommon species of plants require to be kept in pots to protect them from its ravages. This was many years ago; we do not know how the case may be now. We are, ourselves, sufficiently familiar with the Botanic Garden at Berlin, but we do not remember ever to have heard the insect mentioned by any of the establishment. One thing, however, is certain, and that is that wherever it appears it is greatly dreaded by cultivators; and, as Curtis says, it is scarcely possible that experienced gardeners should have thus unhesitatingly stigmatized it if it had done nothing to deserve its bad name. M. Souchez, the great French Gladiolus-grower, is stated to be in the constant habit of waging war by every means in his power against this cricket, in the belief that if it were allowed its own way for a

Perfect Insect, after fifth and last casting of skin.—Insect after leaving egg.
(After Boisduval.)

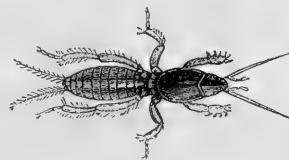

fortnight in his grounds, serious loss would be the result. On the other hand there are some; perhaps many, naturalists who believe that mole-crickets do very little damage, and that the little that they do is not so much by eating as by disturbing the roots in the course of their grubbing and their excavations to form their nests; and the fact that they are certainly carnivorous, so far supports the view that they take. Curtis bears testimony to their carnivorous habits. One that he kept alive with grass turnips in a cage fed upon the caterpillars of the lackey moth, with which he supplied it for some time. Dr. Kidd, in his memoir (quoted by Curtis), says that these insects prefer raw meat, and that they will attack each other, when the victor devours the flesh of the vanquished, which is in accordance with the statement of Bouché, that the mother devours a great number of her offspring, so that out of a hundred not more than eight or ten survive.

The evidence as to its carnivorous habits, therefore, seems strong enough, and no doubt the creature does much good by eating wire-worms and other underground grubs and insects, but the injury it actually does to the objects of the gardeners' solicitude (in whatever way the mischief may be done) is sufficient to warrant us, as horticulturists, in putting it down in the list of our enemies, and waging war against it accordingly.

Before entering on the means of attack we had better reconnoitre and ascertain its habits and history. We shall not occupy the time of the reader by giving a description of the insect, except on one or two points. The figures (all of natural size) which we give are worth pages of description. As to its structure, we shall only say that it is an excellent example of the adaptation of structure to function. The mole's "hand" has often been likened to a shovel. The fore tibia of the mole-cricket is still more like one, or rather a combination of the shovel and rake. Its eyes are small, and adapted for little light, and it has two ocelli on the forehead. The form of the head and thorax, like a

projecting cone, is admirably adapted for pushing their way through the half-opened galleries, and it is so strong that, according to Roessel, it can propel six pounds' weight on a smooth surface. It has two hook-like spines projecting behind like feelers, and which, indeed, serve that purpose *a posteriori*, for, like the mole, it runs backwards and forwards with equal facility. The colour is brown, and the texture (of the head, thorax, and legs more especially) hard and horny, and it is clothed with a rust-brown, silky, short velvety pubescence, which is apparently analogous to the fur of the mole, although why it possess it is one of those points the purpose of which has not yet been made out. The wings do not appear at first; when complete they have a long projecting termination, which will be seen in the largest figure.

These animals usually inhabit a loose, sandy soil, and prefer it dry to moist. In England, indeed, Mr. Curtis says that they are especially found in damp situations, as around the margins of ponds

Larva after third casting of skin.

and along the banks of streams. Curtis is so almost invariably accurate, that one hesitates to dissent from him; but their known habits on the Continent, where they are vastly more common than here, do not allow us to doubt that their proper ground is dry and sandy, and that they are rarely to be met with in rich, heavy earth. They live under ground, and burrow horizontally during the day, but come out at night; and it has been said that they are sometimes luminous at night. The perfect insect flies very freely about at night, and comes into lighted rooms where a window is open. The male makes a chirping noise, which has been compared to the distant whirring of the goat-sucker.

The pairing of the insects takes place about the end of June or beginning of July, or, in some seasons, a little earlier. The female then constructs a nest for her eggs in the vicinity of her burrows. She makes it about four to six inches below the surface of the ground, and in an excavation of the form and size of a hen's egg, to which a number of zig-zag, slightly-inclined paths lead. The walls are moistened with saliva, well smoothed, and built up in such a manner that, with proper care, the whole nest, like an excavated and rounded clod of earth, may be lifted out. A few, more or less straight, flat paths diverge on various sides from it, which are easily recognised by the earth being slightly upheaved for about the breadth of three-quarters of an inch. In addition to this, a few perpendicular openings serve, not only to regulate the moisture of the cell, but also to provide a means of escape to the female watching by the eggs on the approach of danger, of which they are very

Larva after fourth casting of skin.

sensitive and wary. The nest is usually formed on an open unshaded spot, and the ground above it is loosened, and, where it is necessary, the roots of plants are eaten away, in order to admit the full warmth of the sun.

Nothing betrays so surely the existence of a nest as the decay here and there of plants, whose roots may probably not exceed an inch in thickness. The number of eggs in a nest is variable. The average is 200, but more than 300 have been found. At the close of the breeding season, the female does not immediately die off, as is the case with most other insects, but remains as a faithful sentinel in the vicinity of the eggs, and, indeed, in one of the perpendicular openings already mentioned, out of which its head appears. Nevertheless, it does not hatch the eggs, any more than do our other native female insects. It still lives when, three weeks later, the young larvae escape from their eggs, of which, as we have seen, there is reason to believe that it devours many, although it is right to state that the fact is disputed.

The eggs are oval, greenish white, about a line in length and half a line in breadth, and sufficiently firm to withstand slight pressure. The young are hatched in about a month after they are laid. It is thus about the middle of July that the larvæ leave the eggs, although even then newly-laid eggs have been found, and Ratzburg found some as late as the 6th of August. But this, which is the case with all insects, is not to be wondered at, as the female has many eggs to lay, which she does by degrees, and does not immediately afterwards die. At their first appearance, the larvæ are like black ants, about one-eighth of an inch long. During the first three or four weeks the young insects remain together, inactive, and nourishing themselves upon the rich, vegetable earth, or on the more delicate roots in their vicinity, from which we may conclude that freshly-mowned ground would have a special attraction for the female when about to construct her nest. About this time the casting of the skin for the first time takes place, the larvæ then become more lively, and scatter about in various directions. Towards the end of August, consequently from three to four weeks from the time of the first casting of the skin, the second follows, and four weeks later the third, when they are, on an average, one inch in length. They now descend a little deeper into the ground, and begin their winter sleep. It depends greatly upon the weather of the following year at what time they awaken; but when they do, they shortly after cast their skins for the fourth time, and receive wing stumps. The last casting of the skin, before they become perfect insects, follows about the end of May or beginning of June. Of course, these dates do not apply to insects hatched from eggs laid at a later period. As far as has been yet discovered, very dry and very wet summers are alike destructive to the mole-cricket.

Of its natural opponents the most formidable is the mole. Bouché says that a field which contained an infinite number of root-worms and mole-crickets was entirely freed by the moles in two years. Rooks and crows in this country, and choughs (red-legged crows) and hoopoes on the Continent, assist in keeping them under. But we have also very successful artificial means of destroying them. Perhaps the most successful of any is as follows:—

When this strong and well-armed little fellow gets into a bed of choice Gladioli you cannot well dig him out, as you could if he happened to be in an open spot. The way he is killed here (at M. Souchet's gardens at Fontainbleau) is so interesting and effective, that I must relate it. M. Souchet explained it to me; but so many receipts for exterminating vermin are not worth the trouble of trying the second time, that probably I should not have noticed it had he not called a workman and given me an illustration on the spot. When the mole-cricket goes about, he leaves a little loose ridge like the animal after which he is named, and when his presence is detected in a closely-planted bed of Gladioli at Fontainbleau, they generally press the ground quite smooth with the foot, so that his track and halting-place may be more distinctly seen the next time he moves about. This had been done in the present instance in the case of a young bed of seedlings. We saw his track, and a workman, who had brought with him a jar of water and one of common oil, opened a little hole with his finger above the spot where the enemy lay, then he filled it with water twice, and on the top of the water poured a little oil. The water gradually descended and with it the oil, which, closing up the breathing pores of the mischievous little brute, caused it to begin to suffer from asphyxia, and in about twenty seconds we had the pleasure of seeing it put forth its horns from the water, go back a little when it saw us, but again come forth, to die on the surface, hindered for ever from destroying valuable bulbs. Being very strong and well-armed, a single mole-cricket can do a deal of damage in a bed of Gladioli, and therefore the moment the workmen of M. Souchet see a trace of the pest, they take means to catch it as described, jars of water and oil being always kept at hand.

This remedy is not a new one; we know its history. "A simple plan," says Curtis, "of pouring water into their burrows first, and then a few drops of oil which killed the insects, probably by stopping their respiration, was actually purchased by Louis the XV."; and there seems no reason to doubt that the recipe so acquired has continued to be used traditionally in the Royal gardens of France ever since down to the present time. Attempts to improve upon the oil by substituting coal-tar or soap-refuse for it, or by mixing it with turpentine and other ingredients, have been made, but the true rationales of the death of the insect seems obviously to be that the oil closes up its breathing pores, and consequently the simpler method seems also the best. Turpentine has been used to drive the insects away by its smell. Traps, such as jugs buried upright in the places which they frequent, have been found to catch a good many. Fresh sods placed on the borders where they have been observed, have been found to be used as a lurking-place, and many are taken under them on turning

them over in the morning. A more wholesale way, however, is to search for the nests in June or July, before the eggs are hatched, and destroy the whole batch of them; and the best time to seek for them is immediately after rain or a strong morning dew, at least in loose sandy soil, as the openings conducting to the nest are more easily discovered than in dry weather, when they either fall together or are not at all visible. The spots where the plants are withering in patches are recorded as guides to the nests.

The following plan proposed by Kollar, is strongly recommended by Curtis, viz.: to dig three or four pits in September in the infested places two or three feet deep and a foot wide, then fill them with horse dung, and cover them over with earth; attracted by the warmth of the fermenting horse dung, all the mole-crickets about will resort to these pits on the first frost, and may then be easily destroyed.

To the above may be added a precaution mentioned by Taschenberg, which he learned from Richter, formerly gardener to the King of Prussia, in order to protect certain plants from the ravages of the mole-crickets, viz.: to plant them in willow baskets made like pots.

A. M.

NOTES AND QUESTIONS ON INSECTS, VERMIN, ETC.

Wireworms.—I have found these pest attack rape cake placed about an inch underground, and on examining the piece of cake daily have generally discovered them half buried in it. This I have found more effectual as a decoy for wireworm than potato.—W.

Rabbit-proof Plants.—With reference to the list of rabbit-proof plants in my Nos. 1 and 4—why have Goose and Spanish-broom been omitted? A great desideratum for purposes of landscape gardening, is a *cow-proof* plant. Does such a thing exist? It should also be sheep-proof, and rabbit-proof as well. K. O. L.

Ants.—How shall I get rid of these in a small stove? They swarm everywhere. **Larva.**—[Place half-picked bones here and there on the shelves and wherever the ants resort, and when you visit them an hour or two afterwards they will be covered with ants. Have a bucket of scalding water at hand, and drop the swarming bones into it. We have destroyed many thousands in one day by this plan. Pieces of coarse sponge dipped in treacle-water will do as well as the bones.]

Another Insect Destroyer.—M. Cloëz, who is engaged at the Jardin des Plantes of Paris in inventing what he considers a complete inhibitor for plant lice and other small insects. To quote from Quassini's preparation of entomines, it will be sufficiently accurate to say, take $\frac{3}{4}$ ounce of quassia chips, and 5 drams stavesacre seeds, powdered. These are to be put in seven pints of water, and boiled until reduced to five pints. When the liquid is cooled, strain it, and use with a watering-pot or syringe, as may be most convenient. This preparation we are assured has been most efficacious in France. Quassia has long been used as an insect destroyer. The stavesacre seeds are of a species of larkspur, or delphinium, and are kept in a dry place. The seeds contain a doctrine which is one of the most active known, and when it is dissolved in a very small share of it would prove fatal to insects.—*American Agriculturist.* [The stavesacre is rarely now seen except in botanical gardens, and has none of the beauty of the commoner cultivated delphiniums; but seed may be obtained without trouble, and this is well worth a trial].

Remedy for the Apple Maggot.—Two conclusions are inevitable: first, that the fruitous, now so abundant in our cider counties, must inevitably perish were it not for the oak gall and the hosts of apple grubs which have sprung up in the trees; and secondly, that without the assistance of the tomatis the apple crop would be entirely destroyed by this irrepressible insect. Many a proprietor of garden or orchard in Herefordshire, Worcestershire, and Devonshire will contend that the tomatis must be killed, because they peck holes in the apples and pears just above the insertion of the stalk—a fact that cannot be denied, an act which cannot be defended; but the blue titmouse, in particular, is a most useful bird, and indeed greatly to its credit, that gentlemen will find that exactly in the same ratio as they diminish the number of their tomatis so do they increase that of their worm-eaten windfalls. To myself there is no sight more pleasing than a little blue cap searching every crack and cranny in the trunk of an apple-tree for the cocoons of the apple grub; his excessive, his indomitable, industry, the sharpness of his sight, the knowing manner in which he turns his head on one side to peer into the crevices, the drooping of his attitudes, minutely suspicious, thievish, and acrobatic, and his merry, although perhaps somewhat noisy, song, command a hearty sympathy, and indeed to my protection, where I can possibly extend it; but almost every apple-grower of my acquaintance prefers worm-eaten apples to blue-headed tomatis, and I find it impossible to overcome this preference. Supposing, however, that our little chrysalis escapes the prying eyes of the bluecap; supposing no such ill-fortune befall him as to be transferred from his carefully selected retreat to the crown of a little bush, or to the middle of June, the circumstances are much, and is again on the wing, and hovering round the young apples on a midsummer evening as before. "Is there no remedy but the tomatis?" asks some devoted enemy of the titmouse race. Yes, a partial one. By burning weeds in your gardens at this time of year you may drive away this little moth. If you have trees the crops of which you value, make a smoking (mind, not a blazing) fire under each, and a few rods from the smoke, select a green sprig of a little herb, and the apples that have been saved will repel you for that. There again, you may pick every apple that the grub has attacked. This is indeed a radical cure, but who can accomplish it? After all, Nature's remedy is by far the best; for the tomatis will serve you without giving you any trouble, and simply for their own gratification. And then, again, supposing you are possessed of an orchard (mind, this remedy will not do for a garden), turn in your pigs, and let them have a good feeding. Pigs are natural enemies of the tomatis. It is proverbial that a pig always delights in going the wrong way, and I verily believe they like those windfalls all the better from a conviction that they are taking what they ought not. Thus the pigs are fed, and the grubs are destroyed before they have left the stall where they were fattened.—*Ed. Newman, in Field.*

THE ARBORETUM.

DECIDUOUS versus EVERGREEN TREES.

DURING the planting season it may be well to remind the many who are continually planting coniferous and other evergreen trees, without knowing how long they may endure the climate, how futile their efforts are likely to be, and how poor the result they will produce compared with what might be expected if they worked with permanent materials, so to speak. Judging by the scant attention now paid to the planting and grouping of deciduous trees, one would suppose them lower in the scale of attractions than the Conifera, which are planted everywhere. Deciduous trees are really by far the most valuable in this country. There are three weighty reasons why conifers should not be planted so extensively as they are, viz., first, their short-lived character with us; secondly, their inferiority in beauty to deciduous trees; thirdly, their smaller size and inferior majesty of port. A great number of species described as hardy are, for the most part, not really so. They endure the climate for a while, sheltered in sunny nooks here and there, but a severe winter comes and nips them, or an easterly breeze comes and half burns off all the leaves. Unproved exotics, that thrive for a little while, but succumb to some unusually bitter spell of weather, we have given them everywhere places of honour that should be filled by subjects more congenial to our clime, and as a consequence we often find disease or a vacant place where we looked for a long life of dignified beauty.

Not a few are really hardy, and it is impossible to embellish our gardens and country seats without their aid; but none the less is it a mistake to depend wholly, or almost wholly, on them, as many do nowadays. Then as to beauty, they are wholly inferior to our finest deciduous trees—inferior inasmuch as they are changeless, and without the supreme charm of fair blossoms. No pine that ever grew equals in beauty a well-developed horse-chestnut. The different varieties of the common hawthorn also yield more beauty than any pine. Nobody can dispute our classing the Conifera as inferior in beauty to flowering trees. Then as to size and port—on the whole deciduous trees are the largest. On the sierras of California the trees are indeed magnificent, and here and there in Canada you meet with a white pine, the leaves of which rustle plaintively more than a hundred feet above one's head; but in the West the whole size of the tree is concentrated in the trunk, and in Canada and other pine countries you may travel for days without seeing any but small crowded trees. The common deciduous trees of the parks of Europe, with their massive trunks, majestic limbs, and picturesque ramifications, are grander than any pines. Nor in this connection must we compare the giant pines of the West with what we can grow in England. It is a delusion to think that our climate will ever permit the Sequoias and the other great pines to live for anything like the time they have existed in their native homes, the long and brilliant summer of which is certainly necessary to their making a robust growth and perfecting it thoroughly.

In connection with this subject, the utter neglect of deciduous trees should be taken into consideration. Very few seem to take any interest in any of them but the common kinds; and they are hardly ever grouped so that their beauty may be set off to advantage, few developing the handsomest-flowering kinds into good specimens, isolated in open groups, or forming pictures by their aid—which it is very easy to do. But, badly as they are treated, they generally live, even in crowded cities and their suburbs, where conifers and most other evergreens perish annually in thousands; and those who plant them usually have the reward of planting something a little more enduring than themselves. The millions of evergreens planted to perish in the smoke-fog of London were not so worthy of a place as the few young planes once placed in Mecklenburg Square, which are now more majestic objects than one could find in many a wild forest country. Those who plant in all but the most favourable districts will find nearly as much difference in the result of planting deciduous and evergreen trees as the Londoners have experienced; though in every case away from towns a sufficient number of the really hardy kinds should be planted.

L OF C.

The Yellow Pine (*Pinus ponderosa*) and Douglas Fir.—I can remember seeing ponderosa and *Abies Douglasii* growing side by side near the Flower Garden at Scone in 1839, the positions being no great distance from Douglas's native village, in the churchyard of which is erected a monument to his memory. On one side of this is a list of a few of the trees and shrubs introduced by him, the spelling and pronunciation of which greatly puzzle the village rustics. Instead of such names, if a few of the many charming shrubs or trees which he introduced had been planted at the base of the monument, they would have deprived it of the cold bleak look which it now has. My employer has just had a fine specimen of ponderosa cut down, in order to give more space to a splendid tree of Douglas fir, which has reached a height of seventy feet, and which is clothed to the ground with beautiful cone-bearing branches. The circumference of the trunk, a foot from the ground, is eleven feet six inches. The height of the ponderosa was fifty-four feet; and the circumference of the trunk a foot from the ground, six feet. In cutting it up into short lengths we found it to be very full of turpentine. We have had several large trees of different species of pinuses cut up that were killed here during the hard winter of 1860-61, but none had such a strong resinous smell as this. I cannot, however, speak of its value as a timber tree. As far as I can learn it was placed here about 1830. Our soil is a good gravelly loam.—J. M. H., *Ledbury, Herefordshire*.

Notes on Smoke-effects in and about Warrington.—In the remarks which I am about to make, I have strictly confined myself to what has come under my personal observation with regard to the destruction of trees, shrubs, and plants by smoke and chemical vapours, and also regard to certain plants that will not grow, I believe from natural causes. Among evergreens that are most severely injured by smoke, &c., are the conifers. The Scotch fir has long since disappeared with us; so has the spruce. About two years ago we planted one hundred young hemlocks; there are only a few now left, and these are sickly and seen to die in other parts of the town gradually every year. The Arborvitae (*Taxus occidentalis* and *T. hupehensis*), the sycamore, lavender, rosemary, laurentius, and Cotoneaster microphylla are among the plants that, fifteen or twenty years ago, flourished well with us, but have now disappeared. Among plants that just exist are the *rev.* several varieties of heaths, the sweet bay, common laurel, and Portugal laurel. The deadar and araucaria we have not tried here, but I have seen in the town very agreeable specimens. The common hornbeam grows very well with us; the hornbeam and the box are the only trees that are now dying. The evergreen oak (*Quercus Ilax latifolia*) has so far stood pretty well; so has the box. Among evergreens that flourish best is the rhododendron, the plants here are healthy, flower freely, and grow to a large size; the only complaint is the foliage is dirty. The azalea is more vigorous than the rhododendron, and grows almost under any treatment, but the very best of all is the ivy, particularly the Irish ivy, this does not appear to be damaged in the least beyond being dirty. Among deciduous trees and shrubs that stand best in this locality, the common ash, birch, beech, lime-tree, &c., &c., and several other large-leaved elms. The common variegated sycamore has suffered very severely the last two or three years. The birch and Normandy poplar are now suffering to some extent in various parts of the town. The ash, till two or three years ago, was among the trees least affected; its having withstood dense smoke for so many years, and its being not so much affected tends to show that though it will not stand chemical vapours yet it stands thick smoke pretty well. The common lime-tree is still in full flower, and is now suffering severely. Some trees that were able to resist the effects of smoke a few years ago are now sinking rapidly, a sign that they dislike chemical vapours more even than dense smoke. While large elms suffer, the common English elm (*Ulmus campestris*) has so far proved to be one of the very best growing trees in a smoky atmosphere, retaining its foliage longer than any other old-established tree with which I am acquainted. We have but two years ago planted several plane trees (*Platanus acerifolia*), and they are far superior to the best trees of this locality. The common oak stands as well here as in the country. We have also two or three Turkish oaks growing well. Among others that stand well are the tulip tree, common laburnum, lilac, and mulberry, which keeps its foliage well. The hawthorn and elder are the very best of all trees or shrubs to withstand deleterious vapours. I do not think it necessary to say much about fruit trees, beyond stating that red and white currants have nearly succeeded. Blackcurrants still grow well, and are growing better, so far as I can see; but gooseberries still grow well, but the fruit is dirty. Among soft-soiled flowering-plants, dahlias, pansies, primulae, mignonette, nasturtium, lobelia, ageratum, pentenostem, antirrhinum, and a few others, flower very well. For the last few years I have paid some attention to variegated, and fine foliage plants in the flower-garden, and have found that to be the best course to take to get a good display of colour, which is a fine substitute for flowers in a town atmosphere. The rose we used to grow well, but now it is very difficult to find a rose that will stand exposed to dense smoke. The yellow geranium and pink balsams in the vicinity of the silverside, and feels the charm and refreshment of its highest life. The trunks of the trees have caught the ripened red of many vanished summers, and are bearded with long streaming tufts of grey lichen, which impart to them a savage appearance; but they are touched with grace by the wild flowers growing at their roots—childhood sporting in unconscious loveliness at the feet of old age. They form long-drawn vistas of vision, and are the true symbols of the forest. The wavy green and golden *Cotoneaster*, which are indescribably attractive, for they appeal to that love of mystery which exists in every mind; they reveal only enough to stimulate the imagination, and lead it onward to lovelier scenes beyond. It is the same vague sentiment of expectation or hope that gives the charm to every natural as well as to every moral landscape. Life itself without these vistas of expectation would not be worth living. When

A Pine Forest.—A pine forest is one of the most beautiful features of nature. All quiet scenes it is surely the quietest. The harsh sounds of the busy human world, and even the dreamy murmurs of summer, are hushed there; no sound of bird or hum of insect disturbs the solemn stillness; and only at rare intervals the mournful coo of a dove, or the sound of the squirrel, is to be found, and then it is as if the voice of the forest were hushed in the quiet of the silence, and feels the charm and refreshment of its highest life. The trunks of the trees have caught the ripened red of many vanished summers, and are bearded with long streaming tufts of grey lichen, which impart to them a savage appearance; but they are touched with grace by the wild flowers growing at their roots—childhood sporting in unconscious loveliness at the feet of old age. They form long-drawn vistas of vision, and are the true symbols of the forest. The wavy green and golden *Cotoneaster*, which are indescribably attractive, for they appeal to that love of mystery which exists in every mind; they reveal only enough to stimulate the imagination, and lead it onward to lovelier scenes beyond. It is the same vague sentiment of expectation or hope that gives the charm to every natural as well as to every moral landscape. Life itself without these vistas of expectation would not be worth living. When

the sun is shining brightly, and pierces here and there through the dusky foliage, the effects of the chequered light and shade, the alternations of green and gold, are very lovely indeed. In the distance, all round, are the fair pale clusters of delicate ferns, stately boughs of Taxus, waxen balls of Pyrola, and green and crimson leaves of the blue-berry, cover every inch of ground not occupied by the boles of the trees, and form mosaics more beautiful than those of the Vatican. The dim, slumberous air is laden with an all-pervading balsamic fragrance, strongly stimulating that sense which is more closely connected with the brain than any other, and suggesting numberless vague but sweet associations and memories of the past; while through the pyramidical shapes of the tall cypresses, the tall pines, and the tall firs, come close to the earth, as if in sympathy, and appears calmer and bluer than elsewhere by contrast with the dark-green motionless foliage. Beautiful, indeed, is the pine forest in all seasons: in the freshness of spring, when the gnarled boughs are penetrated and mollified by the soft wind and the warm sun, and thrilled with new life, burst out into fringes and tassels of the richest green and masses of the tenderest purple; in the sultry summer, when the pine is covered with a thick, clustered boughs, all dry and crisp, while the open landscape is palpitating in the scorching heat; beautiful in the sadness of autumn, when its unfading verdure stands out in striking relief amid clutched shapes that have no sympathy with anything earthly save sorrow and decay, and directs the thoughts to the imperishableness of the heavenly Paradise; beautiful exceedingly in the depth of winter, when the tiers of branches are covetous with pure, unyielded drifts of snow, sculptured by the winds into curtains of white grace, and bending low, like the swallows of the sky, whisper to each other, and the twitter of the golden wings sounds loud in the expectant hush; it is more than beautiful in storm, when the wild fingers of the wind play the most mournful music on its great harpstrings, and its full diapason is sublime as the roar of the ocean on a rock-bound shore. I do not wonder that the Northern imagination in heathen times should have invested it with awe and fear as the favourite haunt of Odin and Thor; or that, in after times, the long rows of them, vanishing in the dim perspective, should have furnished designs to the aisles of Christian temples, and the sunset burning among its branches should have suggested the gorgeous painted window of the cathedral.—*Bible Teachings in Nature.*

THE EVERGREEN CYPRESS.

(*CUPRESSUS SEMPERVIRENS*.)

THE accompanying is an illustration of three well-known Evergreen Cypress trees which are distinguished for their great age, size, and beauty, and—more even than all these—for having been planted by the hand of Michael-Angelo Buonarroti. They stand in the garden of the Convent of the Chartreuse, at Rome, which is said to be situated on the site of the baths of Diocletian. It will be seen that there are four trees in the group, but that one of them is of a smaller size, and, apparently, considerably younger than the others, and that another is fast going to decay, so that these famous Cypresses of Michael-Angelo will soon be reduced to two.

Michael-Angelo was born in 1475 near Florence, and did not come to Rome—at least, did not acquire such celebrity as would have led anyone to ask him to plant memorial trees, until after the year 1500. We shall, therefore, not be far wrong if we estimate the age of these trees at from 360 to 380 years. We have no recent account of their sizes; but they were measured by M. Simond in 1817, who states that the circumference of the largest was then about thirteen feet.

This is a big tree, but it is by no means the largest with which we are acquainted; for that of Somma, in Lombardy, is nearly twice as thick, viz., 23 feet in circumference, and 121 feet high. That is the tree which is said to have been of the age of our Saviour, and, consequently, may be even older than the great Sequoias, about whose longevity so much discussion has at various times taken place. It is certainly noteworthy, although only confirmatory of what we might expect, that this quality of extreme endurance should be found in the two most remarkable species of Cypresses of the Old and New Worlds respectively; and it applies not only to individuals, but also to the life of the species themselves, which extend back into past geological epochs.

The home of the Evergreen Cypress is the south-east of Europe, Turkey, Greece and its Archipelago, Asia Minor, Syria, Persia, Cashmire, and the Himalayas. In fact, its distribution is parallel with that of the Cedar, except that the blanks in the course of its spread are better filled up than in the latter. Both occur on the mountains of Lebanon, and as the Cedar of Lebanon differs from the Cedar of Mount Atlas, so the Evergreen Cypress of Lebanon has sufficient distinctness to have led to its being described as a distinct species (*C. sphaerocarpa*); but it is merely a variety, and occurs mingled with typical specimens. As in the Cedar, too, the Himalayan individuals differ somewhat from the European, and, like the Deodar, have been described as distinct species under the names of *C. indica*, Roylei, and Whitleyanæ. The degree of difference, however, is less than that between the Cedar and the Deodar, and the latter may very well be

regarded as a distinct species even by those who do not so consider the Himalayan Evergreen Cypress. Whether the parallel can be completed by the extension of the Cypress to the western parts of the Mediterranean may be questioned. So far as we know, this Cypress does not occur on Mount Atlas, but is found, both in cultivation and apparently wild, throughout the Mediterranean region generally. The received opinion, however, is, that in all the countries where it now grows to the west of Greece and Turkey it has been introduced. A statement by Pliny, that in his time there were standing at Rome some Cypresses that were more ancient even than the city itself, would seem rather to lead to the inference that our tree must have been aboriginal there; for although there had been some communication and attempts at colonization or settlement between Greece and Italy prior to the arrival of Æneas in Latinum, they do not seem to have been of such a character as would have included arboriculture or horticulture as one of their elements. Still, on the other hand, Pliny tells us, without qualification, that the Cypress was introduced from Greece to Tarcentum.

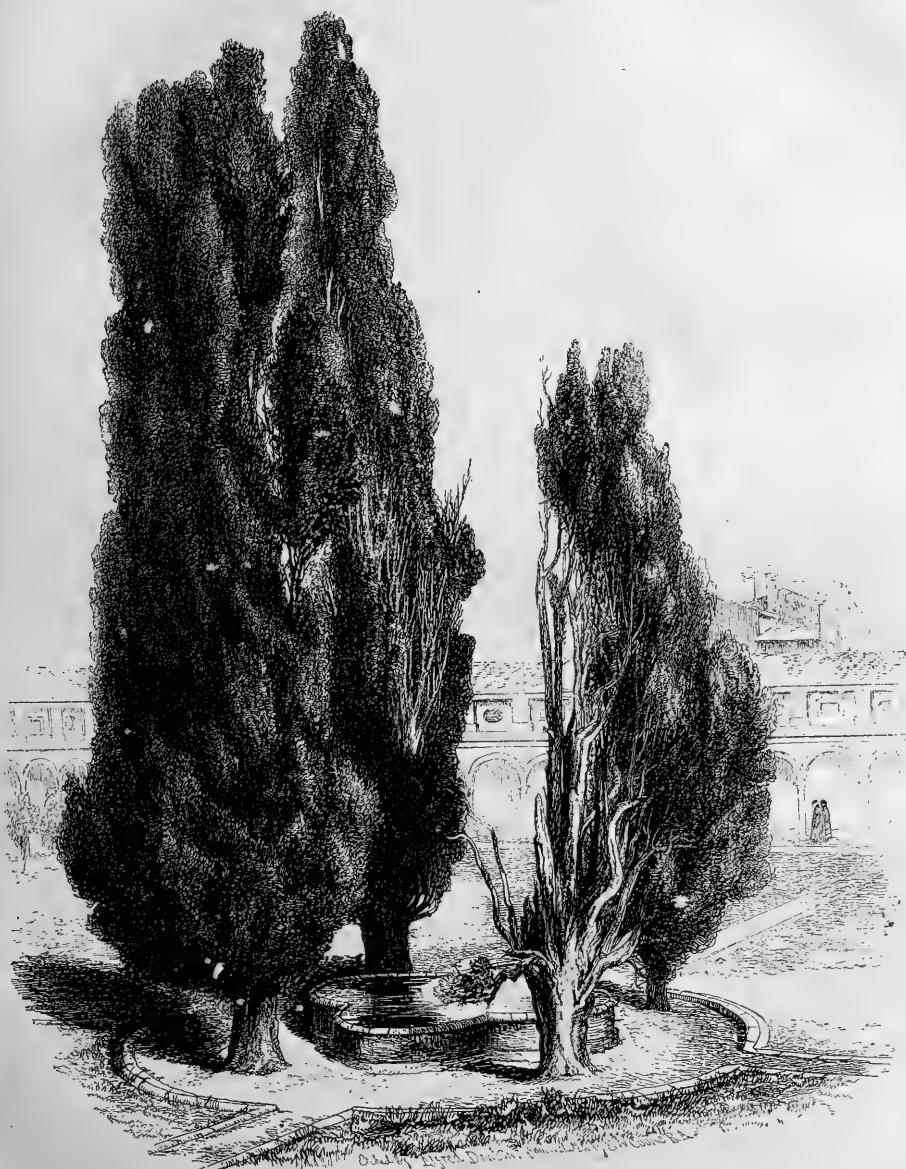

The Cypress has been grown in England for three hundred years at least, but there are no trees anywhere of great age. The climate is scarcely warm enough for Cypresses, and although they withstand ordinary winters, every now and then comes some envious frost which carries them off, so that we have to begin all over again. Mr. Palmer's tables of the effects of the winter of 1860-61 show that out of thirty-seven places indiscriminately reported upon in England there were only eight where the Evergreen Cypress had escaped without injury, while at twenty-two it had been killed. In Scotland, out of seven places it was killed at five, and escaped uninjured at none. There are only two returns from Ireland, at one of which it escaped uninjured and at the other was killed.

There are two very marked varieties of this species distinguished by their habits of growth, which become more especially distinct as the tree gets older—one upright like a Lombardy Poplar, the other spreading and forming, when old, something like a 'head.' The Somma tree, of which Loudon gives a good figure, is of this kind. The upright form is known as *fastigiatæ*, the spreading as *horizontalis*. In former years it used to be a vexed question whether these two were distinct species or only varieties. There is scarcely any question as to this now. We have become more familiar with the vagaries of the Cypress tribe, and we know that similar differences in habit may be observed in almost every species. As a case in point take the Californian *Cupressus macrocarpa* or *Lambertiana*, names respectively given in the supposition that the two trees were distinct varieties; but although the difference in appearance between the two is often as great as that between an umbrella sñut and one open, we have evidence that both have been raised from the same packet of seed. In the same way we have lately had a beautiful fastigiata variety of *Cupressus Lawsoniana* resembling in port and habit the upright variety of *C. macrocarpa*. This variety of form is an advantage to the landscape-gardener, who, with the same species, can thus produce totally dissimilar effects.

The Evergreen Cypress is a tree of easy culture and propagation, and, unlike the Thujas, the seeds begin to germinate in some three or four weeks from the time of sowing. A. M.

HARDY TREES AND SHRUBS.

CONTEMPLATION of the beautiful in nature, not only refines and humanises, but exalts the mind. Who among us does not hail with delight the unfolding of nature's woodland charms in spring? But to appreciate the beauty of such scenery, in its fullest extent, we should possess an intimate knowledge of the materials of which it is composed; for a person who scarcely knows one tree or shrub from another, will derive no more pleasure from a collection of different species of such things than from an assemblage of plants of the same kind. Cowper says there is "No tree in all the grove but has its charms;" nevertheless some species are more effective than others, both in colour and form; and thus when scenery contrived by man is contrasted with that of wild nature, the parts which trees and shrubs play in the way of ornament soon become apparent. What would our landscapes, for instance, be without trees? or where would be the charms of hills, plains, and islands without them? Again, in the case of pleasure-grounds, wrested, as it were, from nature's dominion, the hand of man for purposes for

GROUP OF CYPRESSES PLANTED BY MICHAEL-ANGELO AT ROME.

which nature alone seemed inadequate, we see a farther illustration of the part which a judicious selection and arrangement of trees and shrubs sustain; for the beauties of a pleasure-ground consist in the contrasts which the variety and distinctness of each tree and shrub produce.

The chief interest, therefore, of all gardens necessarily depends on the variety of exotic trees and shrubs with which they are adorned. The different points to which attention should be directed in the study of trees and shrubs are, pictorial form, height, breadth, general magnitude, outline, the mode of growth, spray, and shape and size of leaves. The first qualities, however, in a tree which will strike a general observer, are either its height, width, or the outline which it makes against the sky, or against any object behind it. The characteristic beauty and general forms of trees, I need scarcely say, are infinitely varied, the changes, also, in the foliage at different seasons of the year form never-failing sources of enjoyment to lovers of nature. Trees also furnish shelter and shade, and are the cheapest and least precarious mode of increasing the immediate value, as well as future income, of an estate. To clothe the barren mountain with foliage, is not only a laudable measure with reference to general ornament and shelter, but it is, for the most part, the best purpose to which such wastes can be used. In all cases a more extensive and judicious choice of trees may be made than that which we usually see, and much improvement might be effected in their distribution. In the allocation of different kinds in shrubberies, little interest seems to be taken or knowledge displayed as to the form which the plants will assume at an advanced stage of growth; and thus plantations that have been thickly planted as screens and never thinned, soon defeat the purpose for which they were intended.

Trees and shrubs on lawns should for the most part be disposed in an isolated manner, that is, in such a way that each individual plant may assume its natural shape and habit of growth. When trees and shrubs, however, in a pleasure-ground attain a large size, they very frequently become more or less crowded, and, therefore, destroy the individuality which belongs to each. Therefore, as they advance in growth, they should either be cut in or thinned out, so as to fully develop the nobler individuals and, where possible, to form groups. Half the trees which are planted, whether for ornament or for profit, are either disfigured or rendered comparatively valueless by having been originally planted to closely together, or by being allowed to remain too long without thinning; care should therefore be taken to place them in the first instance at a distance apart sufficient to permit them at a future day to display their individuality. The form and outline of trees and shrubs also vary very much according to the physical circumstances in which they are placed, such as soil, situation, and climate, and we only get the full grandeur of character which an individual tree is capable of expressing when, from its youth up, we save it from being weakened and deprived of light and food by other trees.

In planting trees and shrubs, the first point to be considered is the selection of such kinds as are known to flourish in the particular locality allotted to them, and to thrive in the soil about to be operated upon; the next thing to be determined is the ultimate object in view, viz., whether you wish to create a permanent wood, or to plant merely as a means of reclaiming the land, or for shelter, or for ornament. In the formation of large masses of trees and shrubs, or when trees are introduced into ornamental plantations, they should be kept as much as possible in the background; great care should also be taken that all the taller-growing kinds are placed in the rear of the less vigorous and slow-growing ones; otherwise they will soon overgrow them and, eventually, leave only branchless skeletons, such as we so frequently see disfiguring plantations arid and many country seats. Again, we often find on lawns, groups of trees planted with the full intention on the part of the planter in the outset that the nurses should be timely removed to allow such trees as are intended ultimately to adorn the grounds to assume their natural forms; but these nurses are, in nine cases out of ten, allowed to become robbers, excluding light and air from those trees which they were at first only intended to shelter. Another evil lies in planting trees where they will not thrive, a fact evident in many of our oak plantations, which in numerous cases are curious cradles in which to rear "the wooden walls of Old England." No department of rural economy is so injudiciously practised as the planting of trees, and this is, in a great measure, attributable to an unacquaintance with the forms and sizes which they ultimately attain. Their selection, too often betrays little forethought or reflection on the part of the planter, and consequently the kinds planted are seldom in keeping with the places they occupy. The use of single trees in breaking the formality of an unsightly situation, and in varying an uninteresting surface, is well known. Trees suitable for planting singly should be chosen according to circumstances; such, for instance, as those which

best resist the wind for exposed situations, and those which require moisture for low or damp places. No thick plantations, large clumps, or broad belts of trees and shrubs, should be allowed except in extensive places, or for useful purposes, as timber trees. Where concealment is wanted it can be well enough effected by scattered trees and shrubs, placed so as to form groups; which, moreover, at once convey an idea of extent, by allowing glimpses of open space and glades of turf.

The predilection which different trees and shrubs indicate for different soils may occasionally furnish hints to planters for the selection of species, and prevent that meagre, starved, and poverty-stricken appearance which too often manifests itself, notwithstanding that heavy expenses have been incurred; for trees and shrubs in a state of nature are all indicators of the character of the soil and subsoil where they grow. They also point out its aridity or moisture, a fact which should be kept in mind by the planter for his guidance in the selection of proper and suitable kinds for particular sites, for it is lamentable to see unsuitable trees so frequently planted by persons unacquainted with their nature and habits, in places where they only exist; whereas, if suitable kinds had been selected and properly planted, a very different effect would have been produced. When the planter has only to consider what trees he should like to see growing around him, and not what the land is most suitable for, he can plant what he pleases, as some kinds of trees appear to flourish, and really do so, in most soils for a few years; but, after some ten or twenty years, they become stunted and dwarfed, lose their foliage prematurely, and, either actually die, or survive only to perpetuate the melancholy spectacle of a well-intentioned work injudiciously conducted.

Professor Whitney, in "*The Yosemite Book*"

The Axe Essential.—Most planters about a country home are too much afraid of the axe; yet judicious cutting is of as much importance as ploughing, and it gives charm to scenes of interest, and a fine, bold assemblage of holes of trees without grace or comeliness, for lack of courage to cut trees at the root. For all good effects of foliage in landscape gardening—after the fifth year—the axe is quite as important an implement as the spade.—*Rural Studies*.

GARDEN DESIGN.

GARDEN SCULPTURE.

GARDEN SCULPTURE should, if possible, have an object; and not be dotted here or there with no definite purpose; for, unless this principle be scrupulously observed, detached 'vases,' or other pieces of sculpture, become merely intrusive spots; while, if well placed in suitable situations, as at the principal entrance of a house, or at certain distances apart on the parapet of a terrace, they become very valuable adjuncts to the general effect. It is much easier to regulate the tasteful distribution of such objects near the residence than in the open garden; and consequently lawns and shrubberies are occasionally disfigured with excrescences in the way of vases or statuary in an ignorant and disagreeable manner that seriously offends the trained eye of taste. Statues may, however, be sparingly introduced in the front of dense shrubberies, in which situation they are sometimes very effective; foliage forming a good background; but they should not be placed under the drip of tall trees, both on account of the drip, which would soon discolor them, and because statuary should have a direct vertical light to secure

A decorative screen of garden sculpture.

that brightness of effect which is its principle charm. In certain situations where a solid screen is deemed desirable, a low wall, architecturally embellished so as to form a base for vases or groups of figures, may be resorted to with good effect. For instance, let it be supposed that a broad walk connecting ornamental grounds with a fruit and vegetable garden is left open for the purpose of preserving the effect of distance; the merely utilitarian features of the latter being tolerably well screened to the right and left of the walk by a deep flower border. Still it may be desirable to terminate the view along the walk at a certain distance; in which case a screen formed by a group of sculpture similar to that represented above, would effectively complete the purpose in view, and form a very agreeable object for the eye to rest upon as the closing feature of the vista. But this device could only be resorted to with good effect, and full advantage, in gardens where similar kinds of sculptural features are adopted in the pleasure-gardens; in which case the effect of such a group as that in our engraving would be perfectly consistent in the situation proposed, and would have the additional advantage of seeming to extend the area of the ornamental grounds to some distance beyond their real limits. This last advantage is far from being either an illegitimate or unimportant one, as the restricted space of most of our gardens renders it necessary that, in the art of laying them out, the smallness of their extent should be concealed by skilful arrangements.

H. N. H.

LANDSCAPE TREATMENT OF RAILWAYS.

I know that it is the habit of many who control large estates adjoining railways to ignore, so far as possible, this iron neighbour, and to make all their plans of improvement with a contemptuous disregard of the travelling observers, who count by thousands, considering only the few who look on from the old high-road, or those, still fewer, who have the privilege of the grounds. It is his duty so to illustrate them as to make them command the acceptance of the multitude. He has no right to ignore the onlook of the world, and be careless if the world condemns or approves.

A high railway embankment traversing the low lands of a country estate, if at a good remove from the homestead, is not so awkward a matter to deal with as might at first be supposed. A few years of well-tended growth in a forest screen may be made to exclude it altogether; but care should be taken lest such screen, by its uniformity, should present the same tame outlines with the embankment itself. To avoid this the woody plantation should flow down in little promontories of shrubbery upon the flat; it should have its open bays upon the embankment itself, disclosing at intervals a glimpse of the passing trains; and, above all, the bridge or culvert, which keeps good the water-courses of the land, should be distinctly indicated, and might have its simple decorative features.

All this, if picturesque effect only is aimed at; but if it be desirable to utilize such a monster embankment, it may be remembered that its shelter, if looking to the south, would almost create a summer climate of its own, and would make admirable lee for the forcing-houses of the gardeners, and for the growth of whatever plants or vegetables crave the first heats of the spring sun.

If, on the other hand, such embankment flank the north, its shadow will offer capital nursery ground for the rhododendrons, ivies, and all such plants as are impatient of the free blast of the sun.

And, after all, if these happy accidents of position and opportunity did not favour such special culture, it should be the duty and the pride of the true artist in land-work to ascertain what other growths would be promoted by exceptional disturbances of surface. The finest and highest triumphs in landscape art are wrought out in dealing with portentous features of ugliness; and so unleashing them with the harmonies of a given plan as to extort admiration.

The railway, with its present bald embankments and its baldness of all sorts, is a prominent feature in many of our suburban landscapes. It cannot be ignored, and the study must be to harmonize its sweep of level line, its barren slopes, its ugly scars, its deep cuttings, with the order and grace of our fields and homes. Rains and weather stains and wild growths are doing somewhat to mend the harshness; but a little artistic handling of its screening foliage, and adroit seizure of the opportunities furnished for special culture, will quicken the work. And it is to this end that I have thrown out these hints upon so novel a subject as that of railway landscape gardening.

D. G. Mitchell.

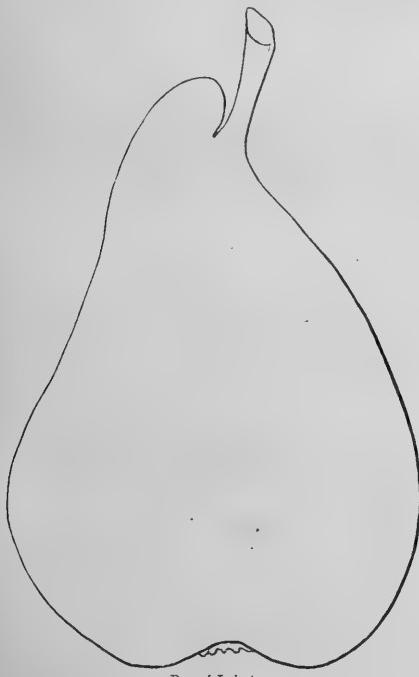

Water.—If the improver will recur to the most beautiful small natural lake within his reach, he will have a subject to study, and an example to copy well worthy of imitation. If he examines minutely and carefully such a body of water, with all its accompaniments, he will find that it is not only delightfully wooded and overshadowed by a variety of vegetation of all heights, from the low sedge that grows on its margin to the tall tree that bends its branches over its limpid wave, but he will also perceive a striking peculiarity in its irregular outline. This, he will observe, is neither round, square, oblong, nor any modification of these regular figures, but full of bays and projections, sinuosities, and recesses of various forms and sizes, sometimes bold, reaching a considerable way out into the body of the lake; at others, smaller and more varied in shape and connection. In the height of the banks, too, he will probably observe considerable variety; at some places the shore will steal gently and gradually away from the level of the water, while at others it will rise suddenly and abruptly in banks more or less steep, irregular, and rugged; rocks and stones, covered with mosses, will here and there jut out from the banks, or lie along the margin of the water, and the whole scene will be full of interest from the variety, intricacy, and beauty of the various parts. If he will

accurately note in his mind all these varied forms, their separate outlines, the way in which they blend into one another, and connect themselves together, and the effect which, surrounding the water they produce as a whole, he will have some tolerably correct idea of the way in which an artificial lake ought to be formed. Let him go still further now in imagination, and suppose the banks of this natural lake, without being otherwise altered, entirely denuded of grass, shrubs, trees, and verdure of every description, remaining characterized only by their original form and outline. This will give him a more complete view of the method in which his labours must commence; for uncoated and apparently misshapen as those banks are, and must be when raw and unclothed, to exhibit all their variety and play of light and shadow when verdant and complete, so also must the original form of the banks and margin of the piece of artificial water—in order finally to assume the beautiful or picturesque—be made to assume outlines equally rough and harsh in their raw and incomplete state.—*A. J. Downing.*

THE FRUIT-GARDEN.

NEW PEAR.—BEURRE LUIZET.

The fruit of which the following is an outline ripened on the 8th of November last year. In shape it may be said to be acute pyriform, somewhat one-sided, rather ventricose at the base, and bent at the top. Skin, clear, greenish-yellow, finely dotted and streaked with russet, with veins and patches of a lighter russet about the stalk, and covered with beautiful vermilion on the sunny side. Stalk, rather long, and swollen at both ends, obliquely set on the

Beurré Luizet.

surface of the fruit. Eye, large and wide open, and set in an even shallow basin. Flesh, compact, white, fine, and melting, without grit at the core. Juice, abundant, sparkling, rich, sugary, and slightly acidulated, with a delicious beurré flavour.

This variety grows freely upon the quince, bears abundantly, and forms very handsome pyramids. It was raised by M. Luizet, a nurseryman at Ecully; bore its first fruit in 1856, and was sent out about 1860. I imported it in 1865, and have found it to be one of our best Christmas pears. It keeps well, and ripens in succession, a

valuable property, as it prolongs the time during which it can be enjoyed.

As with all pears worked upon the quince, the stock should be planted an inch or two under the surface, a practice which will contribute greatly to the health of the trees. The quince stock is exceedingly fond of half-rotted stable manure, a plentiful supply of which should be annually laid over or slightly forked in about the roots. Pears on quinces are, like roses, fond of being occasionally lifted and replanted, an operation which invigorates them.

J. Scott.

ORCHARD HOUSES.

The future of gardening will be more and more under glass. This was the opinion I formed when the duty was first taken off glass. How confirmed one's opinion is now! Is it not ridiculous to suppose that people who can afford to grow fruit at all, that is to say, choice fruit, will be content to pursue plans of culture which must often result in failure? I remember, some thirty years since, walking with an old lady of the old school round her garden in spring, and seeing all her peaches carefully covered up with canvas to protect the blossoms from frost, and hearing her remark, "Is it not absurd to go to all this expense? why, I do not get peaches fit to eat more than once in four or five years." Was it not Dr. Johnson who said he only once had as many peaches as he could eat? There are many favoured places in the south of England where it is worth while to grow peaches on walls; but in the vast majority of places it would be much more sensible to plant pears. Few people know the value of pears. Instead of planting the finest varieties on south and west walls, we find them on north and east aspects, where few can ripen that are worth a wall, whilst the best situations are taken up by unprofitable peaches and nectarines. In our uncertain climate all tender fruit must be grown under glass, if we are to be at all certain of a crop, or care for quality. A rose may be a rose by whatever name you call it, but a peach with about the flavour of a white turnip is not worth calling a peach. If it be determined to build glass houses for fruit culture, the next consideration will be of what form they shall be built. The idea that strikes most persons is to cover their walls by building what are called lean-to houses. For very early vineeries this may be advisable, but not for stone fruit. I never found a house cost less, if you took the number of square feet covered into account, when built against a wall than when erected away from a wall. It is impossible to provide the same ventilation in a lean-to house as you can in a double-roofed house, and trees will fail sometimes against a wall to set their fruit, whilst those planted in the same house in the front of the sashes will be full of fruit. In every respect I prefer a double-roofed house; and if it saves nothing, why spoil your pear walls? Is it advisable to heat orchard houses? After nearly twenty years' experience, I say, yes, if you want a certainty as to a crop, and are anxious for the best quality procurable. At the same time if circumstances forbid the expense, I would still say, to any one south of the Trent at any rate, glass without heat is far better than any wall without glass.

Chilwell.

J. B. PEARSON.

ORANGE CULTURE.

As the cultivation of the orange as a dessert fruit is again exciting some attention, it has occurred to me that the reproduction of the subjoined paper, read before the Horticultural Society of London so long back as March 13, 1820, might not be without interest. For many years I had models of the fruit to which the paper relates, and I have now before me a drawing of two China oranges, girthing thirteen and a half inches, and weighing one pound each. These were grown in 1818, and I have the authority of the late Mr. Donald Munro, so many years curator of the Society's gardens, expressed but a short time before his death, that the collection of the Citrus tribe shown by my late father in that year was the best that had ever been exhibited before the Society. The collection consisted of fourteen species or varieties, a handsome dish of each. These were grown in the garden of J. M. Mundy, Esq., at Shiplake, near Derby, where at that time the regular supply of oranges for dessert was regarded in the same business view as that of peaches, grapes, or pine-apples. For refined and elegant appearance upon the table, nothing can be more desirable than oranges cut with two or three leaves adhering, and sometimes with a spray of bloom.

[DEC. 23, 1871.]

Oranges at Shipley were a speciality: my earliest lessons in the garden being taken in gathering their blossoms for conserves and distillation; and I can confidently affirm that, in a half century's wanderings, I have never seen them nearly so well-grown as they were there. They were managed as follows:— W. P. AYRES.

The greenhouse in which they were grown at Shipley was forty-nine feet long

and seventeen feet wide, with a glazed sashed roof, sloping to the south; the back and sides were solid walls; the front was nine feet and a half high, and had glazed folding doors. The intervals between which were filled with fixed glazed sashes. The front of the house was a single story, built of stone, with arches, and carried under the pavement next to the front glass, the heated air being admitted through ventilators from a narrow air-chamber adjoining the fine. The back wall, on the inside, was eighteen feet high, and that, as well as the sides were covered with a trellis, the openings of which were six inches square. Adjoining the back wall, at even distances from each other, were six trees, covering the wall completely, so that it seemed as if these were growing trees in the following order: 1, a lemon; 2, a Seville orange; 3, a lemon; 4, a Maltese orange; 5, a Seville orange; 6, a lemon. They were planted young, in a border under the pavement, and their branches were trained to the trellis. Citron trees were planted in the same manner against the west side; and these were trained to the trellis at the two sides respectively. Besides the above eight trees, there were twenty-two in tubs, seventeen of which were brought from Malta; they were selected, and when they grew finely, and the fruits they produced were excellent both as regards size and flavor. The remaining five trees in tubs, and all the greenhouse plants in pots were kept in the house in the winter months. The conservatory was some thirty-two feet long; and was divided longitudinally into three borders; the back border was three feet eight inches wide, and its level was elevated three feet above the other part of the house by means of a wall which supported it. A paved walk, some two feet wide, was carried over the border, and a stone curb and root of soil, on which the wall was exposed to view, at the higher, at even distances, which divided one border from another. The lemons were of my own working. The centre border was thirteen feet broad; in it were planted, in a double row, four in each row, at even distances, eight trees, viz.: two standard China oranges, one dwarf China orange, three Seville, and two Maltese oranges; these last were young plants; the other six trees were all in a bearing state. In the front border, which was only four feet wide, were planted, in 1863, six Maltese oranges, and two lemons, and two from the bud, and the other two were lemons. This border was also used for the growth of grapes; vines were planted in the front of it, on the outside, and were introduced through holes in the walls. The trees in each of the tree borders of the conservatory were trained in different ways. Those in the back were fastened to a trellis against the wall. The trees in the centre had their branches in part secured to a row of stakes set along the front and sides of the borders, and the branches were supported by being placed so as to allow the branches to spread evenly over the border, thus exposing the first to sun and light, and also producing a beautiful effect. In the front border the trees were trained flat on a horizontal trellis, after the manner of peach-trees, the trellis being two feet from the ground.

Both in the greenhouse and conservatory the borders were filled at the time the trees were planted with a compost made as follows: To twelve barrowfuls of strong, turf, loam, were added six of good rotten dung, and three of vegetable mould; these were properly incorporated six months previously to being used. This was placed in the bottom of the border, and the top covered with a thin soil of preparing composts in three days, and was described accordingly; but I have reason to know that the compost was used quite fresh, that it fermented moderately, and maintained a gentle bottom heat for several months after the trees were planted. This fact my father, in after life, when bottom heat became better understood, regarded as a potent element of success; and in doubt he was right.) After I had planted both houses, having a few old trees in tubs and pots which were in a good health, I endeavoured to try the effect of a mixture of manure and water on them. I also tried the same waterings of mud, earth, and sand, with the like result. The sickly trees treated in this way were restored to health in twelve months, and as they made fine fruitful wood, I was so satisfied with my new compost and manure water, that I determined to use them in future with all my other plants, whether in borders or in tubs or pots. I have applied them in the manner hereafter detailed, and the beneficial effects resulting from their use have exceeded my expectations, not only in the vigour and richness of the wood and foliage, but in the abundance, size, and quality of the fruit. The compost in question was formed of two parts (a wheelbarrowful) of manure, mineral manure, and two parts of manure water, the mixture being frequently stirred for a week or ten days before it was used, and then applied to the plants owing to the heat of the sun, and the action of pigeons' dung, seven of garbage from the dog kennel or butcher's yard, seven of sheep dung, seven of horse-dung, and ten of vegetable mould; these were mixed together twelve months previous to use. The manure water consisted of three wheelbarrowfuls of cow droppings fresh from the pasture field, two of fresh sheep's dung, and two pecks of quicklime thrown into a hogshead of soft water, the mixture being frequently stirred for a week or ten days before it was used, and then applied to the plants owing to the heat of the sun, and the action of pigeons' dung, seven of garbage from the dog kennel or butcher's yard, seven of sheep dung, seven of horse-dung, and ten of vegetable mould; these were mixed together twelve months previous to use. By the usual mode of manuring and similar trees in greenhouses, however fine the plants, they only serve the purpose of ornament, and are otherwise useless, never producing fruit fit for the table. This arises from gardeners taking these trees out of the house when they put out their greenhouse plants for the summer; whereas they ought to keep them under cover the whole season, availing themselves of the removal of the other plants to give them the peculiar treatment necessary to bring them into bearing. Oranges and similar tropical fruits, I will now, however, defer to the time of February, and the beginning of March, when the trees, if in good health, will begin to show blossom; fire heat should then be increased, say to 55 degs., but the houses ought not to be warmed above 65 degs. at this time even by sun heat, the excess of which must be checked by the admission of air; and indeed the more air the trees have during the time of blossoming, the more certain will be the crop of fruit. Advantage was taken, in cold weather, of the middle of the day for daily work, and the trees were syringed in the morning every day, and when in blossom a rose was used having holes so small that they would not admit a fine needle to pass through them. As soon as the fruit was set I began to water at the roots with the manure water above described, giving more or less according to discretion, and they had no other water during summer, except what little fell from their leaves after syringing.

Early in June the greenhouse plants were set out of doors for the summer, and I then began to force the orange trees, by keeping the heat up as near as possible to 75 degrees, for I do not consider that either citron, oranges, lemons, or limes can be grown fine and good with less heat. Whilst this forcing was going on, particular attention was paid to watering. In June I also gave the trees, whether in borders or in pots of earth, top dressing of cow manure, dried blood, and superphosphate, an application which is of the greatest benefit in causing them to swell their fruit. The surface soil was worked with a small hand fork, taking care not to disturb the roots, all the loose earth was then rammed down to the roots and

replaced with the compost, an operation to which I attributed much of my success in producing such fine and abundant crops.

With respect to pruning, early in February the more unpromising branches can be away taken, room for young trees is more productive, and the trees after a few green shoots are the shoots were more numerous according to their strength in the same way as peach-trees are shortened. Some nicety is required in thinning and arranging the crop. When the fruits are about the size of green-gages it is proper to thin them, so no fruits should never be left together, for they will not grow well with each other. The thinning is to be done according to the condition on the age and strength of the tree. The thinnings being without pulp, when of the size mentioned above, are much esteemed by confectioners and make excellent preserves.

The fruit which I exhibited to the Society was part of the produce of 1818, which was particularly great; that year, nineteen of the older trees yielding two hundred and twenty-eight bushels of ripe fruit, being nearly all oranges, and the largest bore half dozen each, in circumference, from fourteen inches and a half to sixteen inches and a half in circumference; three China orange trees, viz., one in the greenhouse and two in the conservatory; half dozen of fruit, some of which measured thirteen inches round. Six Seville orange trees, viz., one in the greenhouse, three in the conservatory, and two in tubs, bore one hundred and forty dozen of fruit, and the largest were six inches round. The fruit, as it was in the conservatory, three in the greenhouse, and two in tubs, weighed in all, one hundred and fifty-four bushels, and the fruit obtained in a tub, had fifteen dozen of fruit, and from two large trees, in tubs, twenty-four bushels of fruit, were obtained.

NOTES AND QUESTIONS ON THE FRUIT-GARDEN.

Peach Trade in America.—The transmission of peaches over the Delaware Railroad, in a single day, amounted to ninety-eight car-loads for New York, and twenty-four for this city.—*Philadelphia Paper*. [The car-load alluded to is a large railway waggon].

Apricot Disease.—Is the Moor Park more liable to this than any other kind? and is there any remedy? My trees of the Moor Park have suffered much.
Recro.—[It is an unfortunate disease, for which no reason nor remedy has yet been found. The Moor Park is the kind most subject to it. At Frogmore they have removed many trees and planted seedlings in their stead, and as yet the result is satisfactory.]

Remarkably Prolific Apricot Tree.—A Breda apricot tree, growing in the
Baldwin Dell Creek valley, in the year 1888, covering about one-third acre of land,
fructified a wall which had been covered about 1875 by vines, and the following
year produced a crop of 2,000 lbs., and the following
year a crop of 10,000 lbs., Ripe fruit gathered, August 15th, 240; 20th, 600; 24th, 240
29th, 744; 30th, 900; Sept. 1st, 168; destroyed by wasps, &c.,
648. Ripe fruit, 3,852. Thinned for tarts, &c., when unripe, 13,885. Total,
17,707.

Vertical Cordon Pears.—Will you kindly tell me how to form these, comprising a "maiden tree"? *NORTH WALES.*—Nothing is simpler. The leading shoot is cut back to a few buds; the side shoots are left unpruned; the side shoots in summer, at five or six joints from the base of the current year's growth, there is scarcely anything more to be done. Cutting back the shoot annually is usually practised; but it is not really necessary, except when the leading shoot is a weak or mutilated one.]

Fruit-Trees for growing against an Oak Fence.—What fruits would you recommend for growing against an oak fence seven feet high, the fence one hundred and thirty feet each of east and west aspect, and one hundred for fruit trees? I am on the flat, in Gloucester in S. England. The south aspect plant a pear tree; 6 Pears, viz., 2 Queen Louise, 2 Grouville, 2 Beurre Rance; 2 Moorpark or Peach Apricots; 1 Maydulce and 1 Elton Cherry. On the east aspect put 6 pears; 1 Fondante d'Automne, 2 Louise Bonne of Jersey.

2 William's Bon Chrétien, 1 Beurré Ripe; 4 Plums: 1 Denyer's Victoria, 1 Prince Engleborough, 1 Autumn Compôte, 1 Jefferson. Against the north aspect plant Morello Cherries and Red and Black Currants.—Ed.

keep them; birds are on the wing with sharp, hungry beaks, intent on devouring those of geeseberries and plums chiefly, but also any other plumy sorts sold there. The best remedy against any such depreciation is picking without the scot. This acts as a deterrent; after a day or two of frost, they turn up again, and will eat nothing but what you have left over; and if you have any, you ever will,² and at once take wing in search of something else. The eight and a half small of scot ever afterwards is enough, and it is a remedy which is cheap, and easily applied. On one of those foggy mornings, when Queen Gossamer reigns in structures beauty over everything, out with dry soil, and dust each drooping branch and bush, and the soil will stick, and the work is done. If heavy rain dashes the dry dust weather off again, sweep the buds clean, renew the picking, &c. It does the trees or bushes no harm. On the contrary, it is good manure for the roots, and it saves the buds.—D. T. F.

Strawberries in Autumn.—The best strawberry for autumn fruiting with me is PATRIOT'S Seedling, which produces a good crop, and the flavour and appearance are both good. The next best as to productivity is one of which I have lost the name; it is a very distinct variety, but not so hardy as the former, and cannot be relied on after the end of September, except Walter Scott, which is hardy and productive, but it is not so good a crop, though quite good in flavour. It is a small plant, and not very strong, but has a good crop, and pale pink flowers. Blush Prince is in colour, and not very strong. The most hardy of all is May Queen, I have had this within a week of Christmas, but unless thoroughly ripe it is acid, and it is, moreover, small compared with others. The time to keep them in a cool frame as a period of rest must be regulated according to the time they are required in fruit—from one month to four, or nearly as much; but it is not practicable to keep them in a cool frame or under glass for so long a time. They will bear fruit five months (1½ lbs. to the quart) since about the third week in August. Bistro, however, is thought to bear a regular crop until November, and a few of

protection from rain and frost in October and November, such as that afforded by spare lights. It is not absolutely necessary to have forced strawberry plants for securing this autumn crop of fruit. It may be done in the following way:—Having the borders some four feet or five feet wide, about the proper fruiting time, or sooner if the season is more than ordinarily wet, place some spare lights over the plants, and, by this means, and by removing all the fruit before it is ripe, give them their period of rest. Do not keep the lights over them except the time of fruiting (which also ought to have been stated above), for then they will call a current of air over the plants, and, if the plants are crowded, they are destined to be started into growth, except they should be actually dying for want of it. Or some may be grown in pots, as for early forcing, and these are much more manageable, as they can be removed from place to place as desired, and in autumn can be carried to an orchard-house, or even the back or front of a greenhouse, where they will get abundance of light and air. It will be found that forced plants will not do for pots, as they will give but a very poor crop. Since November I have gathered some twenty-five quarts, and there are still fruits in all parts of the bush, but the frost has affected those not covered.—George Lee, Clevedon, "Flower and Garden."

The Cherry Plum (*Prunus myrobalana*).—With such a pretty homely name, one would be justified in supposing this a common plant, whereas it is not by any means so, though it deserves universal cultivation, for two reasons: 1st. It is the earliest of ornamental flowering trees. Before a single tree in the orchard or garden shows a flower, it is a snowy mass, looking as conspicuous in its lonely beauty as a white-sailed clipper on a dark sea. The flowers are sweet-scented, a little more than three-quarters of an inch across, white, with a pink tinge at the base, and a few small red spots on the petals near the tree. 2ndly. Its fruit is edible, and it is worthy of cultivation for that alone. On this point Mr. A. P. Barron says: "When at Burghley Park Gardens, Stamford, I observed several good-sized trees of this pretty little plum, quite heavily laden with fruit. I was informed that it was very much used by the Marquis of Exeter's family, when quite ripe, for dessert, but principally for the purpose of preserving, greatly esteemed and more relished than the Morello cherry, with which it somewhat resembles. The fruit is well suited for bottling and for preserving, like other plums and cherries. Through its habit of early flowering, however, we generally lose the fruit by frosts, except in unusually open seasons, and in some favoured situations, as at Burghley, which is high and dry. The tree is of slender growth, but attains a great size—from thirty to forty feet; the leaves are very small and rounded; fruit, medium sized, of a slightly oval shape, its colour pale red, with a long slender stalk like a cherry-stem. In taste it resembles the Morello cherry, but is not so acid, nor so sour as that of plum. The flesh is yellowish, sweet with a slight acidity, and juicy. Ripe early in July, but will hang on the tree a long time. It has many synonymous names, as Early Scarlet, Miser Plum, Virginian Cherry, Roblet, &c." Enough has been said, we trust, to show that it ought to be made as common in our gardens and pleasure-grounds as the red Hawthorn. If in some low situations it fails to set its fruit, its early bloom will please, even if the cold rains whitewash it with the winter-beaten grass.

PUBLIC GARDENS.

PARKS AND PUBLIC GARDENS IN AMERICA.

(Continued from page 46.)

I WAS much disappointed with Philadelphia, which, though a large, wealthy, and, in many respects, a very interesting city, is very oppressive in the monotony of its long, straight streets. In many of the streets here, too, the house-sewage passes to the gutters through little channels cut in the footway. In hot weather this is anything but a satisfactory arrangement, and it looks more like what one would find in an Irish town awakening to a sense of improvement than in the city of brotherly love. There is a square here planted with the native trees of America, many of them old specimens; but, as usual, they were planted just as if in a dense wood, and with the usual result. They did not add much beauty to the place, nor fully develop their own; nor could they be advantageously seen. But here, again, once out of the town, and in the magnificent Fairmount Park, the visitor is at once struck with the splendid and spirited way in which public parks are made in America. Imagine a piece of ground, stretching back from the margin of a broad winding river with picturesque and rocky banks, 3,000 acres in extent, and boldly and beautifully diversified, in all parts! If this park be wisely treated in the natural manner, and all the money and thought spent upon it devoted to embellishing it with hardy trees and other subjects that thrive in the region, it will surpass anything we know of; but if it falls into the hands of those who, instead of enriching it with natural beauty, go far to remove all traces of that by making the beautiful surface geometrical here and there; by constructing expensive fountains and costly bridges; by statutory, &c.—in a word, by denaturalising it—it will be a great misfortune for public gardening. Here, too, there is a wonderful cemetery, hundreds of acres in extent, on beautifully diversified ground; and clean, well kept, and well planted. In this cemetery I gathered specimens of a beautiful *Gordonia*, a shrub with fragrant white flowers, something like those of *Magnolia glauca*; and the whole was in effect a vast and well-kept garden.

Of Baltimore I have the same story to tell: a vast public park, as sweetly diversified as a bit of Switzerland, and commanding noble views of the surrounding country. Here, too,

saw the trail of the serpent just alluded to, in the shape of two long lines of ponderous vases, ranged along a short drive near the entrance, all of the same pattern, looking like stone sentries keeping the streets. If the Baltimoreans let that sort of thing go on, Nature will soon become quite subordinate to the stone-cutter or the stucco-moulder in their beautiful park.

Boston is, to my mind, more agreeably laid out than any other large American city. The streets are not rigidly rectangular, as is generally the case, but are more like those of an English city, and certainly cleaner than those of any of the other large eastern cities. It has an immense advantage, too, in being cut up by very broad salt-water boulevards. Boston Common, which all have heard of, does not, to the stranger, seem an attractive spot, and a public garden formed on one part of it is, to our mind, as ill-looking a pattern as man ever designed for his delight. There is no breadth and no repose in it, and a dotting-about of beds and borders everywhere, and a piece of water in the centre appears to have been designed from the pattern that would result from placing three fiddles with their necks together, and then tracing a mark around them. It will be apparent what I mean—a hybrid between the geometrical and the natural form of fountain basin; the whole surrounded by a vertical margin of stone. But I hear Boston, like many other cities in the States, is thinking of a new park, and I doubt not that it will be worthy of her status among American cities. Here I noticed a very desirable kind of wide street between two rows of houses having a belt of grass in the centre, with trees and shrubs and flowers, the roads passing on each side of this and between the central strips of grass and garden and the houses. Here, too, is a beautiful cemetery—Mount Auburn. In this, as in other large American cemeteries, a pleasing and, to a stranger, a novel way of naming the paths, walks, and rides through the cemetery, is in use. Thus, we see "Cowslip Path," "Lavender Path," "Primrose Walk," "Oak Avenue," and so on through quite a catalogue of names—mostly pretty English names. Some of the paths, however, are unfortunate in their names, *Pelargonium*, *Craëgus*, &c.; but let us hope that these dreadful ones were only discovered after all the English names of flowers and trees had been exhausted.

Unfortunate Chicago, before the fire one of America's great cities, and in Europe reputed to be the great city of the West, by some unhappy mistake often called the "garden city," is not a nice place. It is large and thriving, but the situation is very low, and its surface not broken up by the grand rivers and estuaries that sweep through the great cities of the eastern coast. Looking over its surface from a high building, it is more suggestive of Chelsea or the flats of Rotherhithe than of Manhattan or Boston Harbour. There are a few fine streets, and some hundreds not fine; and there is a tremendous population of rats that hive under the wooden footways. Here, too, the sweet practice of leaving the garbage in the gutter for many days prevails, and some of the streets are long enough for a pilgrimage. The city is on the margin of the great sea-like and clear Lake Michigan. One would think they would welcome its glassy surface and sweet air, as in no other part near does Nature come to speak to them, so to say. Not so: they throw their rubbish into it, and drive dirty railway waggons along its shores, and in various similar ways shut it out from the view of the town. Here at least two parks are in course of construction by, we believe, Mr. Olmsted, the designer of the Central Park at New York, a gentleman excellently qualified for the work, and who has the broadest and truest notions of the most essential things in public gardening. In connection with these parks, fine tree-planted boulevards are being made to connect one park with another, and to open up, in an effective manner, parts of the suburbs which will one day, no doubt, be densely covered with houses.

Washington, the capital, is well and boldly laid out; the streets magnificent in breadth, and frequently well planted with trees, though much remains to be done in this way. With streets 160 feet wide, you may plant trees without darkening the windows. The situation of and the views from the city are very fine, and there is not a little interest for the horticulturist here, in consequence of this being the head-quarters of the Agricultural Department.

THE SQUARES OF LONDON.

(Continued from page 85.)

The gardening in our squares is of a peculiarly lugubrious description, and of a style quite apart. Hardy subjects are not made a study of, and the bedding plants with which the country is ablaze in many parts are rarely seen. Year after year the same tone of slimy melancholiness is assiduously preserved. The trees crowd upon each other, and only those that tower above all, and assert their beauty and dignity in spite of the gardener, are seen to advantage. Any flowers planted usually soon perish in the solemn shade. The walks, generally designed so as to cut through and destroy the prettiest spots in the square, appear to receive most attention, but it is sometimes shared by the ugly, high, and elaborate seats piled round the bases of the beautiful trees so as to interfere with the effect of their stems as seen across the lawn. All the necessary seats, as well as tool-houses and arbours, should be placed near or towards the sides, where they would be useful without being obtrusive. It is quite easy to place all such objectionable features so that while as convenient as if piled up in the centre, they shall not be objectionable from any point of view.

The gardeners of the squares are a mysterious, not at all understood race. Occasionally, an individual may be seen emerging from a public-house in the near neighbourhood, pipe in mouth, and presently, gaoler-like, unlocking the gates of his gloomy retreat and disappearing within its shade. That is all we know of him, save we will pass him by for the present. Any beauty our squares possess is independent of their designers or care-takers. All present nearly the same dead level of feeble monotony. An idea, however, has been carried out in Golden Square, so original that it deserves an illustration, which will also save verbal description. The materials employed have all the merit of simplicity—earth, old drain-tiles, and a chopping-block! If it be too much to hope for a system which would beautify our squares, may we not pray for a public inspector with power to remove any objects that make them resemble the playgrounds of lunatic asylums?

The best feature of the London squares are their noble trees. Driving or walking through the north-western districts you frequently come upon Planes which would command admiration in the

Bed in Golden Square, July 13, 1870.

largest forests. Huddled together, at first, with a number of miscellaneous trees, these, thanks to their splendid constitutions and noble stature, towered above the masses of overcrowded shrubs around them, and spread forth their grand old boughs so freely that each tree seemed as if it wished to fill up the square. Free from disease, regardless of dust, asleep, but how very beautiful in sleep! When the multitudinous fires are active around them in winter, these glorious trees give us in our dreary waste a glimpse of the beauty of the grand wild woods. And let it not be thought that the Plane is the only tree that would thrive perfectly in our squares, even in the most smoky and crowded parts. It would take a list longer than this article to enumerate all the beautiful deciduous trees and shrubs that grow in the temperate and colder regions of the world, and the great majority of which would do perfectly well in our London squares, if properly planted and attended to. It would be perfectly easy, even with our present knowledge, to select as many beautiful trees that would thrive in the squares of London, as would represent in them the brake and forest beauty of every important cold region in America, Europe, or Asia. To select such trees and shrubs, and plant them so as to secure to each a due amount of light and air for its development, would prove a very desirable occupation for those interested in our squares.

The few kinds that have raised their heads above their fellows eloquently tell the advantage of paying chief attention to the planting of hardy trees. Here, for instance, is a peep into Lincoln's Inn Fields, which may help to show some of their beauty. This square, fortunately, is not cut off from public view on all sides by miserable masses of Privet and crowded Lilacs, and here and there isolated trees are seen that would be remarkable around our finest and oldest country seats.

It is utterly impossible to give an idea of the islets of lovely and brilliant flowers into which our squares could be made by this plan,

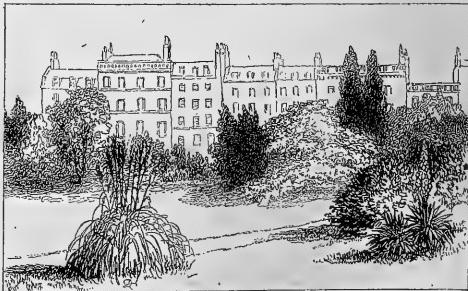

The system of planting evergreens should, on the other hand, be discontinued, except in the case of a few kinds in suburban and open squares. The best plan would be, with all the evergreens annually purchased for London planting, to make a gigantic bonfire on the 5th of November every year. Many of them being of a resinous nature, would afford the boys a very satisfactory blaze. We should in this way effect two objects—save our squares from being defiled by the soot begrimed dying evergreens, and quickly spend at the same time the

View in Lincoln's Inn Fields, June 1870.

large sum of money which people will persist in throwing away on evergreens every year.

One noteworthy way of producing variety would be the devoting of one square to the trees and shrubs of particular country; one, for example, might have British trees and shrubs alone, another American trees, another Chinese and Japanese trees and shrubs, and so on. The greatest improvement that could be effected in the London squares would be the intelligent planting of hardy trees and shrubs; an improvement, moreover, which could be carried out at a comparatively small cost. It would be permanent, too; and permanence in these matters simply means saving of constant trouble and expense. But there is no reason whatever why the squares should be devoted to hardy trees and shrubs alone. On the contrary, the best way would be to allow much latitude, so as to secure variety. When our municipal bodies begin to understand the management of city gardens, one of the first principles they will discover is that each square and small garden should differ as much as possible from

View into a properly arranged Square.

its neighbours. Some of the suburban squares might be devoted to that evergreen vegetation which cannot be grown in the central parts; some in all parts might be gaily decorated with bedding and fine-foliaged plants; others chiefly with hardy border and spring flowers; one might even be devoted chiefly to rock plants, and so on. But nothing of this kind could be attempted unless all or most of the squares were under one responsible head, who could determine what was best to do in each case, and select a man acquainted with the

spécial branch to carry it out as well as possible. As arranged at present, all the squares are managed almost exactly alike. How to unite them under one responsible and efficient chief or department, it is not my object to point out; at present it may be impossible to do so; but assuredly we shall never know how much our squares are capable of pleasing and instructing us till a reform of this kind is effected.

Of the opening of most of our squares to the public I have said little, but those who have seen the happy crowds who frequent the sparkling little squares in Paris, will probably consider this an important aspect of the question. Private interests and public prejudice may be against it now, and may long continue so, but I have no doubt that in the interest of all it is the true plan. It will yet, I trust, be adopted in all parts of London, as the advantages enjoyed by those who "possess keys" are surely not such as need prevent their offering the boon in question to the poorer inhabitants, many of whom, perhaps, seldom have an opportunity of seeing more of nature than is visible in the streets of London. Once devoted to public use, and under intelligent supervision, a modest allowance from the public purse would suffice to convert the squares into some of the most beautiful gardens that ever refreshed the spirits of man. They would save many from the attractions of the public-houses, which are now permitted to flaunt their destructive allurements at every corner. No part of a city should be without places where persons might meet and talk and rest in the open air. In Continental cities, what with the seats along the tree-planted boulevards and squares, this is quite possible; but how very different in London! With us men are literally driven to the public-house; and public-houses necessarily with us assume an importance unexampled in any other country—forming, indeed, the chief feature in our street scenery. The squares would also, even if they did nothing else, help to save the nation of London children from the gutter. An important subject in connection, with squares and city gardens is that of playgrounds. No system of city gardening can be good which does not meet this want. It is not enough to have open spaces or beautiful little gardens; we should keep the children from the filth and dangers of the crowded streets. The best way, in the case of all large cities, is to have, as far as possible, squares or open spaces arranged as playgrounds alone. These should, as a rule, be planted with large trees, so that nothing could interfere with the sport below. This plan would have the effect of drawing off the most frolicsome and noisy elements from the garden squares, leaving them quiet, and almost free from danger of damage. As a rule, no playground should be made in a garden square. The smaller class of square would do best as playgrounds, and there are not unfrequently in large cities open spaces which, by a trifling expense, might be made into recreation grounds of this kind.

The numerous old cemeteries in all parts of London would, if properly embellished, prove as useful as any squares of similar size; and some of the large suburban cemeteries, now so much surrounded by London that they must soon be closed, would make excellent public gardens. To no other use should they be put, and it is in nearly all cases quite practicable to make old cemeteries into pleasant city gardens without displacing the monuments, and thereby destroying the associations of the spot. All such places should be religiously preserved for ever to the public.

Since writing the above, I have visited most of the great cities in the United States. They have few squares, and those very badly arranged, and I am more than ever convinced of several things—first, that London is even now better provided with squares than any other large city; secondly, that these squares are managed so as to conceal any beauty of which they are capable; thirdly, that, by a system, some of the main features of which I have endeavoured to indicate, these squares might be made beautiful in themselves, and have the most beneficial effects on the aspect of many parts of London.—*British Almanack and Companion.*

A Winter Garden in Rome.—Among the various improvements likely to take place in the Eternal City as a consequence of the cessation of sacerdotal rule is the creation of a winter-garden in its centre. Attached to the garden there is to be a magnificent theatre, and also a *café* and a grand arena for open-air performances and concerts. It is somewhat strange (though some may think otherwise) that no recent improvements of this kind have been originated in Rome by the Papal Government; the creation of the noble Piazza del Popolo and the beautiful promenades of the Pincian Hill having been suggested and carried into execution during the French occupation at the beginning of the present century. As Palms, Camellias, Agaves, and other beautiful plants which cannot contend with the severity of our British frosts, will bear the comparatively mild winter of Rome with little injury, the projected winter-garden may be made highly picturesque and attractive. A December walk in the Villa Borghesi, which is one of the pleasures of Rome, is

sufficient evidence of the fine effects that may be produced by judicious plantings. The groves of evergreens, and the early springing up of Cyclamens on the grassy slopes of the Villa Borghesi, render that promenade a very delightful one to strangers, who, in such places fully realise all those dreams of the beauty of Italian scenery and the softness of the Italian climate which are, in too many respects, so sadly disappointing.

H. N. H.

NOTES AND QUESTIONS ON PUBLIC GARDENS.

Want of Plan in London.—Mr. Lowe has been thrashing another department. East London has got a park—Victoria Park—and wants to enlarge it. London, however, had advanced the money for the park on condition of being recouped out of the sale of certain reserved lots, and is accordingly selling them for building purposes. A deputation of East Londoners, headed by Mr. Reed, on Saturday fortnight waited on Mr. Lowe, asking him to suspend the sales, but he said that it was his duty to fulfil the contract, and that the lots were the property of East London, and East London must pay for it. The statue was clear, and England cannot pay for East London. "The argument is unanswerable; but Mr. Lowe forgets that it is not the fault of London, but of the country at large, that it is without the institutions which every other city enjoys, which create municipal feeling and elicit local liberality. Nobody does or can bequeath a fortior to East London, as he might to any city with a decent constitution. We believe the failure of successive Cabinets to organise London costs the metropolis half a million a year."

Hampstead Heath.—Mr. Le Breton, the chairman of the Parks and Open Spaces Committee of the Metropolitan Board of Works, writes to *The Times* that the brief report of his speech at the meeting of the Board which appeared in that paper of Saturday week does not convey the full effect of the remarks which he made with regard to Hampstead Heath. What he then stated was that the Act of Parliament for the preservation of the heath required the Board to maintain that open space as nearly as possible in its original state and in its aspect, and to drain, level, and improve where wanted. He said that it was the duty of the body to repair the mischief which had been done by digging and removing sand and turf, to restore the herbage, fern, gorse, heather, and broom, to plant judiciously, and generally to endeavour to bring back the heath to the beautiful wild condition in which it was some years since. Mr. Le Breton adds that persons unacquainted with the provisions of the Act desire that the heath should be laid out as a park, and even that were allowable under the statute, it would be a foolish waste of time and of general appeal. The protection of the heath, owing to some legal difficulties, was only completed at the end of last month, and no time has been lost by its present owners in taking measures for the protection of the trees, some of which are in danger of falling, obtaining plans for drainage where wanted, and generally doing all that is necessary for restoring the heath to its former state, and for improving and preserving it.

Desecration of City Graveyards.—Are we not becoming too much accustomed to the idea that anything which is sacred may be treated in a肆ious manner? That such a large sum and the labour of so many after the Great Fire of London appears to have been taken in rebuilding the City to reserve in the main the burial-ground of the parishes in which the churches themselves were not rebuilt. They are dotted as green spots all over the City, as many must often have observed. When the present extensive buildings of the Bank of England were erected, one whole parish was swallowed up. It was generally understood that its churchyard was not, and is represented by the modern church of St. Clement Danes, which gives such character to the old church and its site. St. Clement Danes' parish appears to view the subject in another light, and makes short work of the matter. Some years ago one of its burial-grounds, situate in Portion Street, was disposed of for the site of part of King's College Hospital, and all trace of its former use has now disappeared. We have just heard that it has parted with another of its burial-grounds, adjoining Clement's Inn, for the site of a portion of Newgate. One burial-ground is its present one, the middle of which is the church of St. Clement Danes, and still remains to the parish. An effort is being made, in connection with the Law Courts, to induce the parishioners to sell this also. Can we hope, after what has been done, that they will be proof against it? I trust we may. Sites can be got without invading these small churchyards, which may have been bought over and over again by those who lie in them.—*W. Butterfield*, in "*Times*."

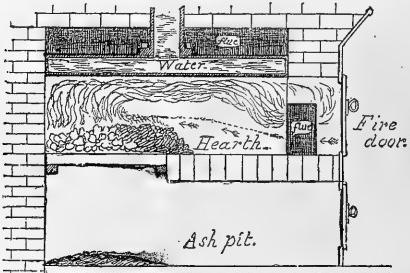

Watering Roads.—Some idea of what might be done by improved management is given in a report drawn up by the chief surveyor of St. Pancras, and laid before the vestry of that parish. The report is a subject of interest watering. In 1867, says Mr. Scott, had a diary of a water-cart kept during a week in the height of the watering season, and he found that through an average working day of 10½ hours (exclusive of the intervals for breakfast and dinner) the time of the cart was thus occupied:—Filling at the stand-post, 1 hour 20 minutes; distributing water on the roads, 50 minutes; travelling to spread the water and back to the stand-post, to and fro, 8 hours 7 minutes. Since that year additional stand-posts have been established, and from observations taken at the stand-posts the following results followed:—Filling, 2 hours; distributing, 1 hour and 30 minutes; travelling to and fro, 6 hours 30 minutes. This, however, is a favourable average; as, where only one cart works from a stand-post, so that there is no loss of time by waiting, the maximum time occupied in filling is but 2 hours 10 minutes. As the distributing will occupy only about 1 hour 36 minutes, the time occupied in travelling to and fro is 6 hours 14 minutes under the most favourable circumstances. It may, therefore, be taken that only about one-third of the time is occupied in filling, about one-twelfth in spreading the water, and about two-thirds of the day in travelling to and fro. By additional water-posts it has been reduced nearly to the minimum under the existing arrangements, and no further economy can be effected without a complete alteration of the system. A change proposed by Mr. Scott is the adoption of a water-van that will hold 450 gallons, instead of the ordinary water-cart, which holds about 220 gallons. This water-van, he alleges, will be in every way an improvement upon the water-cart, which will distribute the water evenly over the surface, and by reason of the height of the distribution from the ground causes a cloud of dust to arise (whatever the weather is hot and the surface dry) from the force with which the water falls upon the road. The van, holding 450 gallons of water, will occupy nine minutes in filling and six minutes in spreading the water, but will only occupy three hours and fifteen minutes in travelling to and fro, so that in seven hours it will accomplish as much work as the present water-cart effect in ten hours. By substituting 50 of these vans for the 71 water-carts which during the watering season are employed in St. Pancras, Mr. Scott estimates that a total saving of nearly £1,000 a year will be the result, and that a great improvement will be effected in the method by which the roads are at present watered.

A Warning.—God grant that the very sight of the calamity with which we have stood face to face may fall out in some valiant, practical resolve, which may benefit this whole nation, and join all hearts as the heart of one man to do that which is pointed to by plain and terrible facts—that, as far as we have power, no man, woman, or child in Britain, be he prince or be he beggar, shall die henceforth of preventable disease. Let us repeat, or amend that general neglect of the well-known laws of health and cleanliness which destroys thousands of lives yearly in this kingdom, without any regard to the knowledge of science, of humanity, and of our Christian profession. Two hundred thousand persons, I am told, have died of preventable fever since the Prince Consort's death a few years ago. Is that not a national sin to baffle all our hearts as the heart of one man? Oh! if his Royal Highness's foul and needless disease, by striking once at the very highest, shall bring home to us the often-told, seldom-heard fact, that this same disease is striking periodically and unmercifully among the very lowest classes, let us do our duty to our fellow-men, and to our dogs—if this illness shall awaken all loyal citizens to demand, and to enforce, as a duty to their Sovereign, their country, and their God, a sanitary reform in town and country, immediate, wholesale, imperative—if it shall awaken the ministers of religion to preach that, till there is not a fever alley or a malarious ditch left in any British city—then indeed has fair and precious life will not have been impeded in vain; and generations yet unborn will bless the memory of a Prince who sickened a poor man, then sicken, and all but died as poor men die, that his example—and it may be heretofore his exertions—might deliver the poor from dirt, disease, and death.—*Canon Kingsley.*

GARDEN STRUCTURES.

A NEW MODE OF SETTING THE SADDLE BOILER.

As saddle boilers are usually set they require attention every two or three hours, and, indeed, the length of time during which boilers generally will last without fuel is a point on which too little thought has hitherto been bestowed. In my case my aim has been to set my saddle boiler so as to lose as little heat as possible. As it is usually fixed the flames rush out at the further end, curl round the flues, and avoid the sides of the boiler. My plan has been to distribute the flames as is done in warming a brick oven, and to place the fuel in such a way that any cold air which might find its way through the bare grate should not reach the sides of the boiler. This is effected by lowering the flue opening, a principle always observed in the construction of the splendid furnaces which may be seen in the manufacturing districts. When the flue opening is thus lowered, the hottest air cannot escape until it has parted with its heat. But the great point is to have the flue to come out at the door end, thus completely avoiding that through rush of air so universally experienced in the old way of setting this boiler; while

in my plan the cold air, running over the fuel, assists in its combustion, after which it rises and floats thoroughly heated under the boiler top.

My saddle boiler, set in the old way, produced feeble results on account of the defects just pointed out, and the constant influx of cold air through the door, which cannot be kept out however well the door is fitted; but when I altered the setting of it I had no further trouble. The pipes under the new arrangement always remain hot for ten or twelve hours together. The accompanying woodcut will illustrate what I have been doing. It will be seen that the grate is made smaller, and that it is confined to the back end, while the dark aperture close to the door will be recognized as the outlet of the flue; the further end being bricked up so as to leave the boiler space like a small oven. Under such circumstances the flue may go down the sides and over the top of the boiler in the usual manner; but, let it be observed, that the top never heats; therefore the flue may as well go right away and leave the top uncovered.

In stoking, let the hot fuel be at the back and the cool in front, as seen in the representation. Below the dotted line the air is cold, and the direction it takes is shown by little arrows; the directions of the flames will indicate the hot air currents.

If I were setting a saddle boiler, I should carry the flues straight

back to the right and left of the boiler, then unite them at the further end, and put a damper vertically down into the flue. This would retain the hot air completely, but if the damper is up the chimney, the heat will accumulate there also. Fire ascends, and therefore your boiler ought to be higher than the flue and damper.

The Cedars, Chiswick.

A. DAWSON.

NOTES AND QUESTIONS ON GARDEN STRUCTURES.

Hot-Water Apparatus.—Now that so many buildings are heated by hot-water apparatus I beg to offer a few remarks upon their preservation. 1. The water used for filling them should be only rain water, which will prevent the boilers fuming for many years. 2. The water should be changed each year, it being run off quickly as possible, so as to carry all sediment with it. 3. Never boil water in the apparatus, as the iron soon softens, and becomes open until having nearly closed the damper in the chimney, so as to prevent any sudden rush of cold air into the furnace. A sudden rush of cold air in severe frosty weather across a hot cast-iron boiler is very likely to crack it—particularly the bottom ring of a tubular boiler: and although a hot-water engineer and boiler-maker, I like to see all work last out its fair time.—*Dwight Campbell*, in "Builder."

How to Heat a Small Conservatory Free of Cost.—A few years ago a friend of mine bought a house, one of a row; it contained two sitting-rooms on the ground floor—one to the front, the other to the back. In summer the back room was for the conservatory, a close range the wall which separated it from the kitchen of the adjoining house. This suggested to me an idea which has been carried out successfully. In planning a new villa, I placed the kitchen fireplace in the west gable; the space behind the range was left open, and against this was built a conservatory, 14 feet by 8 feet. The open space behind the range is furnished with a wooden door over which, in the thickness of the wall, is formed an air-flue, having a damper. By shutting the damper, the heat from the range is carried off, and the conservatory is in a state of temperature in the conservatory during winter, but has sufficient to protect plants from frost, and to cause some to flower during that season, can be maintained free of cost.—S., in "Builder."—Another correspondent of the same paper says (assuming the kitchen fire to be out at ten o'clock at night) that by this plan the conservatory would be found to be quite cold in the morning, when a little warmth would be most desirable, and suggests the following as a more effective method of heating such structures:—The system here is to have the kitchen during the day full of water, say forty to one hundred gallons. This can be raised to boiling point in about two hours, and all the ordinary kitchen operations going on just the same; then pass the air over the reservoir and out to the conservatory. The mass of water will retain its heat nearly intact until morning, and thus do effectually what is attempted.

Roof Gardens.—But where is the space? may be asked. So may be asked, where is the space for a garden in an uncleared forest? The space for gardens in a city is equal to that of the whole city, less the streets and passages; in short, it is the whole space occupied by the buildings. So then the buildings are to be pulled down, converted into flats, and given up. Not so, for the roofs of the buildings are permanent. It is impossible to make flat and permanent roofs—roofs permanent as a foot-pavement? I think not. I'm sure it is not a difficult operation, if set about with common sense. We have for ages made flat roofs to ships at sea—I mean the decks. Planks nailed down side by side are caulked with tarred or pitched hemp. The planks are wet naturally in some climates and artificially in others, and their constant swelling stretches the joints tight, and makes them water-tight. The same is true of wine-skins, where the liquor does not run out. We put the skins and liquors in stone bottles, and we cork the openings with an elastic cork—the corks swell and the liquor does not run out. The difference between these arrangements and that of the flat roofs that let in water is, that in the one case the materials are elastic, in the others brittle. For many years past a valuable building material has been in use, slate, sawn or cut into large tables of any required size, from four to eight or thirteen feet in diameter. If we suppose iron walls to be built up in a square, and overlaid with a solid table of slate, projecting a foot beyond the walls, and with a descending edge to prevent water running underneath to the walls, it is evident that nothing short of a Swiss flood descending the Rhine, and rising upwards, could get access by way of the roof. But we can't get slate so large. No; but we can get very large slates, and we can put them together so as to be water-tight. How? As we joint wine-bottles with corks, cork the edges of the slate plates. These roofs will be very light, will be dry, will be very efficient, and will last a very long time, and can be very easily replaced if needed, without the slightest difficulty of access, and at a very trifling cost. So now we have got a really flat roof with a slope, say of half an inch to the yard, to lead away the rain water, and over-hanging the wall, with a cornice all round and a parapet six inches in height, to prevent rain from falling over or into the street. On this parapet is an ornamental railing to prevent accidents, and a paved walk on the top, paved on the house-top, as well as on the roof, in the street below. The slates are laid on layers of iron or wood—or iron and wood, the edges being kept together by iron dogs. But the slates are only an inch in thickness, and are exposed to heat and cold. Well, the rain and the snow will not affect them, for the cork provides against that. . . . And now as to the cost. This kind of roof, once in demand, would cheaper than ordinary roofs in first cost, and immeasurably cheaper in maintenance. The roof would be at a much lower price than walls. The system available for the reduction of smoke for open-air purposes, but for greenhouses perhaps it might be accomplished to-morrow. Every separate house or room might at once possess what is at present the peculiar luxury of people who happen to possess corner houses. If a London builder about to erect a row of four-roomed cottages were to adopt such a system, it would be equivalent to adding another story as a garden to each house, with the same outlay and without increasing ground-rent. The system will be of great service to put out growing smokes and carry water on the roof, in addition to provide for the operation of washing and drying without slops in the houses. But we must get the Legislature at work to compel smokeless arrangements in dwellings as well as in factories. Looking back in these pages, they seem so unusual as to read like a romance. Gardens on our house-tops! Babylonian luxuries! But I am nothing if not practical. And, for my own part, I shall feel greatly obliged to any critic who will demonstrate to me that any part of this proposition is either not practical, or not practicable; in short, not a matter of pounds, shillings, and pence, by which landlords may reap profits and tenants reap a large amount of comfort and health.—*All the Year Round*.

THE PROPAGATOR.

THE ART OF GRAFTING.

"You see, sweet maid, we marry
A gentle scion to the wildest stock;
And make conceive a bark of baser kind
By bud of nobler race; this is an art
Which does mend nature: changes it rather: but
The art is nature.—SHAKESPEARE.

DEFINITION OF GRAFTING.—Grafting is an operation which consists in uniting a plant, or a portion of a plant, to another which will support it, and furnish it with a part of the nutriment necessary for its growth. The plant which receives the graft should be furnished with roots; it is destined to draw nutriment from the soil, and transmit it to the part grafted. It is called the stock. We shall mention a few exceptions where the stock is a simple cutting without roots; but it is planted in such a manner as to be soon furnished with them. The other plant, or portion of plant, which is grafted on the stock should have at least one shoot or eye, and be in good condition—that is, neither withered, nor mouldy, nor decayed, nor wet. It is called the graft or scion; it is analogous to a cutting in communication with the soil, and continues its normal growth through the intervention of the stock. Notwithstanding the intimate union of the stock and the graft, they preserve their individual character and constitution distinct: their layers of wood and bark continue to be developed without the fibres and vessels of one converging with those of the other. It is, as it were, a federative union which leaves to the interested parties their independence. Not unfrequently the union of the grafted pieces suffers a clean severance at the point of contact, either in consequence of the weight of the branches, the violence of the wind, or some other casualty. However, the parts thus broken may be used again, either as stocks or grafts, just as before. Almost all dicotyledonous plants may be grafted. Up to the present the monocotyledonous plants have been tried without success. Their structure does not present the least capacity for the adhesion of the parts when put together; and without this intimate union, grafting is impossible.

OBJECT OF GRAFTING.—The object of grafting is—1st. To change the character of a plant, by modifying the wood, the foliage, or the fruit which it was required to produce. 2nd. To excite the development of branches, flowers, or fruit on the parts of a tree where they were deficient. 3rd. To restore a defective or exhausted tree by the transfusion of the fresh sap of a vigorous kind. 4th. To bring together on the same stem the two sexes of monoecious plants, in order to facilitate their reproduction. 5th. To preserve and propagate a great number of woody or herbaceous plants for use or ornament, which could not be reproduced by any other means of multiplication. Without grafting, our orchards would not contain such rich collections of fruits for all seasons; our forests would be without a large number of important kinds of trees; and we should not experience the pleasure of seeing in our parks such a brilliant array of native and exotic shrubs. There remains one more observation to be made in favour of grafting, that is that the plant, or rather fragment of plant, grafted on another preserves its original qualities and characteristic properties. It will produce branches close or spreading, leaves purple or silvery, flowers white or rose-coloured, fruit large or small, early or late, exactly resembling the variety from which it was taken, and without being influenced by the neighbourhood of, or contact with, several similar kinds grouped on the same stock. We could also quote instances of plants which, when grafted, grow more vigorously than when on their own roots. If it is considered that grafting is easy to be practised, that it involves only a trifling degree of bodily exertion, and develops a love for gardening, it will be allowed that it is both a useful and an agreeable operation.

CONDITIONS OF SUCCESS.—In grafting, a great deal of the success depends on the skill of the operator. The other conditions essential to success are affinity in the species, vigour of stock and graft, the condition of their sap, their intimate union, the season and temperature.

C. BALLET.

(To be continued.)

THE KITCHEN-GARDEN.

POT CULTURE OF THE TOMATO.

MANY objections have been urged against this mode of growing tomatoes; but owing to the changeableness of our climate, uniform success need not be expected out of doors. It has been asserted that plants in pots would be infested with red spider, but with plenty of water applied to both root and top, that little pest may be kept from ever getting a footing.

Ripe fruits may be had by the end of April by sowing in the previous autumn, and keeping the plants growing on steadily in a pine-stove or cucumber-house, allowing a rather limited quantity of fruit to remain on each plant. To have them by the end of May, seeds should be sown in the beginning of January. The young plants soon come up in a genial temperature, like that of a cucumber-house, and a six-inch pot will be large enough to admit of a good many being raised; a friable loam is a good soil for them during their earlier stages, afterwards they may have a compost consisting of four parts loam and one part stable manure with a few quarter-inch bones incorporated with them. Tomatoes require to be potted very firmly, burying from a quarter to half an inch of the stem at each repotting. But little drainage is needed, and three, five, nine, and eleven, or thirteen-inch pots are the sizes required for the different shiftings. The pots get filled with roots very quickly, from nine days to three weeks at the most being long enough between the shifts. When put into their fruiting-pots leave a space of one-and-a-half or two inches at top for surface dressings of equal parts loam and dung, to which may be added a little bone dust. Liquid manure should be given as soon as the roots find their way out of the bottom of the pots; watering with it every time the plants are dry, until the fruit begins to ripen, when it should be exchanged for clear water. If grown in melon-houses under as much light as can be given them, the plants make rapid progress, and when the fruit begins to change colour they may be removed to a cool-house. It is necessary to pinch the shoots just above the fruit, so as to keep the plants "stocky" and dwarf. About thirty tomatoes is a plentiful crop for one plant; nothing is gained by leaving too many. After the early fruit has been gathered the plants may be placed in a cold frame, keeping up a genial temperature by husbanding sun heat, and paying attention as before to stopping the shoots; remove also all decaying leaves, and water constantly with liquid manure, giving a slight top dressing about once a fortnight. When the soil gets higher than the rim of the pot, arrange it so as to form a sort of basin for the reception of water. Under this treatment, a large quantity of fine tomatoes may be had from a dozen plants in eleven or thirteen-inch pots. In warm seasons, they would doubtless do well plunged at the foot of a south wall, where they should be mulched and kept well watered. I find the Improved Dwarf Orangefield best for pot culture. Goliath produces large and handsome fruit, but it is too robust for pots. Of Defiance I have no personal experience, but it is said to be very suitable for this purpose, being dwarf and remarkably prolific.

R. P. B.

PROTECTION OF BROCCOLI.

Though broccolis vary very considerably in their powers of resisting cold, but few or any of them can be warranted zero-proof or anything like it. Already the frost has nearly reached that point in some localities, and but for its night-cap of snow, much broccoli would have been wrecked. As it happens, I believe most of it has escaped. But frosts equally or more severe are probably in store for us, and as we cannot command the snow to come to our aid, it will be wise to be well provided with protecting material. True, it is almost impossible to find one to equal snow in potency and efficiency. But that is no reason why we should not use the best materials within our reach. Among these may be enumerated asparagus tops, dry bracken, and clean straw. The first are the best. If cut before they are dead-ripe and kept in a dry place until wanted, and then laid lightly over the crowns of the broccoli, it is astonishing how much frost they will keep off. Each delicate spray shuts two doors against the loss of heat, and the material is so light that it cannot injure the plants protected. The common bracken is almost equally good as a protection, possessing the characteristics of lightness in an almost equal degree. Both these protectors are likewise difficult of displacement by winds. So much cannot be said of straw—the first wind is almost sure to displace it. Being composed of single rods, as it were, it has likewise a great tendency to drop between the plants. For these reasons it should only be employed when the others cannot be had. Some use boughs of Spruce Fir or branches of evergreen shrubs. They will keep off frost, but they bring other evils, such as the dropping of the needle-like leaves of the former into the broccoli, and the flavouring of it with laurel or other leaves. Still, with these

drawbacks, boughs are good protection against frost. But every gardener grows asparagus, and if the tops are carefully preserved, enough will mostly be found to shelter the whole stock of broccoli from the rigours of winter to such a degree as to carry this most valuable crop safely through.

D. T. F.

NOTES AND QUESTIONS ON KITCHEN-GARDENING.

Fennel.—The common Fennel of our gardens (*Foeniculum vulgare*) was formerly much cultivated in America; and in the early days of New England it was the custom of the settlers to carry sprigs of it to meetings, to keep them away from long sermons. The plant is not yet entirely obsolete; and, in the more primitive portions of the country, the bunch of fennel is still to be seen, and the meeting-house is redolent of its odour. Another use for the plant was found by those who kept bees, who were in the habit of rubbing the inside of the hive with it at swarming-time, under the impression that the odour would attach them to their new domicile. It is sometimes smoked like tobacco, as a remedy for colds. In classic times the plant was held in great esteem. Pliny tells us that it was much used in kitchens, that fennel roots were seasoned, or dishes served up, without it. The modern Italian cook uses it as a salad herb; but it has not found much favour in England in this capacity. Phillips, however, states that it eats very tender and crisp when earched up as celery, which should be done at least fourteen days before it is used. The same author, referring to the old superstition that snakes were very fond of fennel, and cleared their eyes with its juice, says that he planted it on a bank in his garden, where he had frequently seen snakes, and frequently found the stalks wounded and eaten nearly half through, although the replies whom he supposed to have been the offenders, were never caught in *Agraria delicto*. The evidence seems to us scarcely strong enough to convict the snakes of culprits.

How to Grow Good Horse-Radish.—Any out-of-the-way corner it is generally safe to grow Horse-Radish, but my plan is to put it in one of the best quarters of the garden. Planting is the way in which I place it every year, and for four years in succession on the same piece of ground. I turn the ground two feet deep, giving it at the same time plenty of rotten stable manure. I then form some four-feet beds, like those for onions, slightly treading them. Between the beds I make alleys about eighteen inches wide and four inches deep. Then I go to my old Horse-Radish bed and take the roots all up. The thickest ones I save for present use; the next size I score for plants for my new beds, selecting the straightest, as long and straight as possible. With the back of my pruning-knife I clear the soil around each root with a long smooth planting-stick made holes sideways in the beds in such a way as to leave the ends of the roots under ground the same depth as the tops, say three inches, planting about one foot apart. This should be done in November, and in spring all the tops will break out from the sides of the beds; the roots will be found free of space to grow in, and by planting sideways plants for another year can be readily raised. They may have grown in one year a single stick of Horse-radish twenty inches long and six inches thick from a very slender root.—*TRUSTON SOUTHWORTH, Castle Head Gardens, Great North Lancashire.*—[We have never seen Horse-Radish grown in the way just described; but straight clean sticks of it have been produced as follows.—The ground, a light black sandy soil, was manured and deeply trenched. Dibbles in rows were then made in it, some fifteen inches deep, and into these were dropped crowns of old roots, the holes being left open. Thus treated, we have seen sticks produced in one season as thick, but, if we recollect rightly, scarcely so long, as that named by our correspondent.]

THE AMATEUR'S REMEMBRANCER.

In-Door Department.—However winterly the weather may be it is surprising how much floral beauty may be had in doors even at this season, if, in addition to a little conservatory or greenhouse, there is a forcing-pit, heated by hot water and furnished with a bark bed in which to plunge the pots. In this, bulbous plants may be brought into flower at any time, and among these may not be forgotten that sweet-scented, beautiful little plant, the Roman Hyacinth. Of that universal favourite, too, the Lily of the Valley, there can scarcely be too many. Another charming plant that will stand gentle forcing well is *Luculia gratissima*, the great Hydrangea-like clusters of blossoms of which rank among the most fragrant of Christmas flowers. Roses and similar shrubs should also be brought forward in succession. Start some Vines in pots, in order to get a few bunches of early Grapes. For cumbrous maidens a moist, growing temperature of from 60 degrees to 70 degrees, or even a little more in the middle of the day, and water occasionally with weak liquid manure. Seakale and Rhubarb may now be pushed slowly into growth; but do not follow the old-fashioned way of covering them with heaps of leaves and manure out of doors. Take up the roots, place them in a covered box for example, and bring them forward in a little warmth. Both Seakale, Rhubarb, and Chicory may be forced and blanched in this way.

Flower-Garden and Shrubberies.—Where the latter are so planted that the shrubs flow over on to the turf, little attention in the way of cleaning will be required, and this is the way all shrubberies should be arranged. Shrubs encroaching too much on one another, or running out too far over the grass, may now be pruned in. Keep walks clean and neat. Choice beds of Tulips and other bulbs should be protected with mats or other means from frost. For the coral garnished branches and spray of Hollies there is now great demand for weaving into wreaths and other tasteful devices for house decoration, and those who keep a few evergreens in pots, plunged in some out-of-the-way corner, for the ornamentation of entrance-halls, windows, &c., will be busy getting them up and dressed for that purpose. Among these should be some of the gold and silver Hollies, which are very effective by gaslight. Little groups of Holly, with different coloured leaves, intermixed with dwarf Firs, Laurustinus, Skimmias, Aucubas, especially such as have been induced to bear fruit, Laurels and Box associate nicely with statuary, and add life and interest to niches, recesses, and other places in which they may be placed. In warmer positions such beautiful berry-bearing plants as the different varieties of Solanum

Capsicum, Ardisias, some of the new Japanese Aucubas, and dwarf Orange trees might be used with advantage, especially if intermixed with bright-leaved Dracemas, and such plants as Poimstis pulcherrima, the great scarlet bracts of which are very brilliant and striking. With materials such as these, and cut flowers for table ornament arranged according to the directions given by our tasteful correspondent, "W. T." our houses need require little more in the way of Christmas decoration.

Fruit and Kitchen Garden.—Pruning and mailing must be proceeded with whenever the weather is very favourable for such work. Finish up planting of all kinds, and throw up vacant ground rough, to be acted on by frost. If not already done, lay down broccolis with their heads to the north, or take them up wholly with balls, and replant thickly in some sheltered place, covering, during severe weather, with light, dry peat, haulm, fern, or boughs of evergreens, a protection which should also be applied to such as have been left in their growing quarters. Give air on all favourable occasions to young cauliflowers in shallow frames, or under hand-glasses or cloches, to stand the winter. Carrots sown late, to draw young, should receive some slight protection on the occurrence of frost. Lettuce and Endive should also be protected under temporary frames. Clear autumn-sown onions some dry day from weeds, and sift some dry earth amongst them. In frosty weather, wheel out manure to quarters where it will hereafter be wanted.

J. M.

OBITUARY.

DR. BERTHOLD SEEMANN.

This distinguished botanist and traveller died at the Javali Mine, Nicaragua, on the 10th of October last, at the early age of forty-seven. He was an intrepid traveller, and had assisted in explorations in many parts of the world. Although lately much engaged with important mining concerns in Central America, he was none the less enthusiastic botanist and collector, and quite recently our gardens have been greatly enriched through his efforts. Dr. Seemann was born at Hanover, in the year 1825. After receiving an excellent education in the Lyceum of his native city, he obtained the degree of Doctor of Philosophy at the University of Göttingen, and was appointed, in 1846, naturalist on board her Majesty's ship *Herald*, in which capacity he made a voyage round the world, and three cruises to the Arctic regions in search of Sir John Franklin. He next dared to face—and faced with success—the perils of scientific investigation in the South Sea Islands and in the dismal swamps of Central America, while at the same time he edited the solitary English scientific "Journal of Botany" and the "Flora Vitiensis," which latter he just lived to complete. As a scientific writer Dr. Seemann was widely known by his "Narrative of the Voyage of H.M.S. *Herald*," published in 1853; "A Popular History of Palms," in 1855; "The Botany of the Voyage of H.M.S. *Herald*," in 1857; "Viti—an Account of Government Mission to the Fiji, Fiji Islands," in 1862; "Popular Nomenclature of the American Flora," "Paradise Vividominoensis;" "Twenty-Four Views of the Coast and Islands of the Pacific;" and "Dottings on the Roadside in Panama, Nicaragua, and Mosquito," written in collaboration with Captain Bedford Pim, and published in 1869. Dr. Seemann was also a frequent contributor to the leading scientific journals of London and editor of the "Bonplandia." He was likewise a Fellow of the Linnean Society of London and Vice-President of the Imperial German Academy Nature Curiosorum. We deeply regret the loss, in the prime of his life, of such an energetic and accomplished naturalist.

The French Horticultural Relief Fund.—It has been determined to transmit all the monies collected for this fund to M. Rivière and some of his colleagues, for distribution as they may think best. This suits us to the best advantage under the circumstances, as persons solicited to receive the money can alleviate but a few of the many pressing cases, and these are best known to the French gentlemen entrusted with the distribution of the fund. The losses are estimated at something like £105,000; let us, therefore, hope that British sympathy will be exerted more heartily in behalf of the sufferers before the subscription list is finally closed.

Crystal Palace Company.—At the annual meeting which took place the other day, it was stated that the past year had been a satisfactory one. The average daily attendance during the last twelve months, it was said, amounted to 1,600,000 persons, and the number was not less than 2,150,000, or the highest number that had ever visited the Palace in any one year. The total earnings for the year amounted to £139,330, and the expenditure to £65,023. After providing for debentures and preference stocks the balance would be sufficient to pay 2 per cent., and still leave a margin; but, upon maturely considering the subject, the directors felt it to be their duty strongly to advise the meeting to accept the smallest rate of 1½ per cent. The Crystal Palace had already been heavily taxed for the past year, alone, not less than £15,000 was so expended, or an increase of £3,324. And they had been advised by their engineer that there were other repairs, especially the renewal of the roof, which would not bear delay, and must be done if the company would keep the building in a safe and sound condition. The expense on that account, therefore, in the coming year was not likely to be less than in the past. The aquarium, it was mentioned, paid a small rent. Since its opening it had been visited by more than 40,000 persons, and the average daily attendance was 2,000, which gave a promise of greater success in the future. Another new source of revenue was the establishment of a curling pond, the entire expense of making which was borne by the Curling Club. It was suggested that some restriction should be placed upon the issue of free passes, which last year reached the enormous number of 100,000.

THE GARDEN.

"This is an art

Which does mend nature : changes it rather : but
THE ART IS NATURE."—*Shakespeare*.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER.

Readers who may find it difficult to procure the numbers regularly through the newsagents or booksellers, may have them sent direct from the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance. "THE GARDEN" is sent to subscribers by Friday evening's post.

EVERLASTING FLOWERS.

(THE RHODANTHES.)

THESE interesting subjects deserve a better fate than usually befalls them. Many lovely things deserve the name, but they are so badly grown or so badly selected and arranged that the very name must be offensive to many sensitive persons. The close-fitting bundles sent from Germany are cases in point. They often contain flowers, too, that have no real claim to the term "everlasting." The most evident mistake made by those who gather and preserve everlasting flowers is their neglect either to gather or properly preserve the loveliest of all everlasting flowers—the different varieties of Rhodanthem.

If cut at the right time, the whole plant retains its fulness and beauty, and the flowers that pure but delicate rosy tint, till Rhodanthes are fit to gather again the following autumn. By that time, if not protected by a glass, the flowers are often obscured by dust. All the Rhodanthes are what is called "half-hardy annuals," requiring some such treatment as follows: Sow in March or April on a gentle hot-bed, or in a close frame without bottom heat, the latter mode succeeding perfectly, unless the seeds are sown too early in the season; they may even be sown in the open borders at the end of April or beginning of May, but will not then flower so early. It matters very little about the Rhodanthem flowering early, but it is of the greatest importance that it should flower well; and this may be as well attained by sowing it on a warm light and sandy border the first week in May as by any other means. Cover the seeds with about one-eighth of an inch of fine sandy soil, and take a little more pains with the sowing than is usual or necessary with annual flowers. But, to make sure of a crop, sow also some seed on a gentle hot-bed or common cold frame, to be planted out when an inch high. There are two or three beautiful congeners of this exquisite plant, all worth growing, though it can hardly be said that any of them is more beautiful than the old one; but if they only approached it, they would be valuable. One is called maculata, and is more robust, with larger flowers having a dark crimson ring round the centre; there is a pure white variety of this. Another is atrosanguinea, a new and distinct species, with dark eye. The most vigorous and beautiful plants are, however, raised under glass for greenhouse decoration, as described in THE GARDEN of December 16th, p. 73. If when they flower they are not cut, but allowed to seed away like the other annuals, they will, of course, soon perish; but if on any fine day about ten days after the first flowers begin to open, and when some are fully expanded—colour a lovely rose, with the back or outer portion of the drooping, bell-like flower gradually shaded off to silvery pink, through the little scales which make it look like the neck of a dove; some opening, and numerous pretty buds around those—they cut as much as you want (cut them off near the ground), and place them on a shelf in a dry room—a darkish room for choice. They will prove ornaments for "in-door decoration" which the artificial florist can never approach.

As to arrangement: well preserved Rhodanthem blooms with a few graceful ornamental grasses make a lovely composition, and far superior to any of the ugly hay-like bundles so much sold now, with dozens of kinds of flowers dyed and otherwise

jammed into them. The colour of the flowers of Rhodanthem is so exquisitely delicate and pretty, and so likely to invite close inspection, that it is desirable to place them under close bell-glasses, where they may remain unsoldied by dust. We know one little tuft of Rhodanthem garnished with a spray of most graceful grass (*Bromus briziformis*) which was placed under a glass shade in 1865, and which now looks almost as well as ever.

PLANT LIFE IN TOWNS.

THE health of towns has become a hackneyed subject, but we seldom hear about the health of plants in towns. Yet the two are not only nearly correlated, but well-nigh identical. Were plants healthy, the inhabitants would probably be so likewise, and the reverse is true. Towns in or near to which plants refuse to thrive are also those most fatal to man. The primary foundations of health in both are heat, light, food, cleanliness, pure air, and suitable water. With the single exception of heat, which in the open air may be assumed to be nearly equal in town and country, it must be admitted that large towns imperil the purity, lessen the quantity, and interrupt the constancy of most if not all the other essentials of health. In many large towns the light of the sun is obscured for more than one-half its shining hours. Therefore, who can wonder at the pale faces which one finds among men, women, and children, and the shabby aspect of plants in towns? Heat is the great quickener, light the chief strengthener, of plants. They ever turn towards the light. The reason why so many die in dwelling-houses is that they have so little light. They linger, pine, and refuse to grow in many towns for the same reason. The pestilence that kills plants by thousands is bred of that semi-darkness which hangs as a death pall over so many of our smoke-capped cities. When that darkness flies before the rigid enforcement of a Smoke Prevention Act applied to every fire, then indeed will plants in towns rejoice, be clothed with new strength and adorned with fresh beauty.

Of the importance of food in sufficient quantity and of congenial quality little need be said. It is alike essential to plant life whether in town or country. Short rations mean weakness; unsuitable food breeds disease. The earth in its natural condition is one great storehouse of plant food. Not such earth, however, as is common to most towns—an "omnium gatherum" of all kinds of refuse. In such unsuitable root-rooms, nevertheless, many town plants are expected to find their food. Is it any wonder that they fail? Plants in towns have many special trials to endure which we have little power to abate. But we can provide good earth, fully stocked with food, for their roots. Whether planted on the sides of our streets, in town squares, or in the open parks, every tree should have a space of the following dimensions wholly for its own use: It should measure ten or twelve feet across and four feet deep, and be stocked with the best maiden loam within reach; smaller shrubs and flowers to have provision made for their wants on the same liberal scale. Were this done at first planting we should have fewer complaints of town plants refusing to grow, becoming unhealthy, or actually perishing in so many instances.

Cleanliness is another grand essential to health—it is its parent, alike in the vegetable world and the animal kingdom. The best cure for dirt on plants is the water-hose overhead. Daily, or rather nightly sounings will keep them, in the dirtiest towns, tolerably clean. In public parks and town squares the whole of the gravel, even more than the grass, should be kept thoroughly watered, if plants are to be kept clean. Prevention is better, as well as much easier, than cure. The dust is laid on with more ease than washed off plants after it has been sown broadcast over them by the wind. If the streets and all paths are kept thoroughly watered, the great pest of dust, which works such disfigurement and injury among plants in towns, will be well-nigh abolished; and when that happy day arrives—as come it must, in the interests of plant life, if not in our own—when every chimney consumes its own smoke, town plants may remain as clean, or cleaner, than those in the country: for in the latter we cannot afford to water dusty roads, as is done in all large towns.

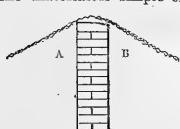

Finally, plants in towns suffer from lack of water. The air is fire-parched and smoke-dried, and the earth is often riddled like a sieve below, and made waterproof on the surface. Town trees are not only starved for lack of food, but literally shrivelled up for the want of suitable water. Drought above and below kills more plants in towns than all the other evils I have specified. The mischief is great; but the remedy is at hand. Water-pipes and sewers run full past the parched plants. Turn a stream of both on to these, and their health and strength will be established. If sewage is not accessible, clean water always is. It will be observed I use

the term "suitable water." All water is suitable but such as is very hard, or poisoned with mineral or chemical substances. Scop-suds is one of the best of applications to almost all plants; rain, or river water, is much better than that of springs. The secret of success in watering is thoroughness. To the roots, much and seldom must be our motto; to the tops, every day, or rather, every evening, if practicable, during dry weather. But these overhead showers must not be trusted to for watering the roots. The latter must have enough to drench them through to their lowest depths.

D. T. F.

Suburban Trees and their Destroyers.—Nothing has appeared in your columns in which I take more hearty interest than in your efforts to arouse public attention to the wretched condition of our London squares, and to what they might be made if properly managed, and also to the want of more trees for both shade and ornament on the principal thoroughfares leading from town to suburban districts. But there is another matter of even more importance than the planting and proper management of such trees as it is desirable to have, and that is, the preservation of those that already exist. London is rapidly absorbing on all sides what a few years ago were outlying districts. If its present rate of progress is continued, this generation will see many of the villages that are now situated half-a-dozen miles from the town properly so called, united to it by interminable lines of bricks and mortar, and, unless an effort is made to preserve the few trees that at present flank the main roads, the suburbs will soon be as leafless as the heart of the city. The road to Southgate is pronounced by all acquainted with it to be one of the prettiest round London. Many of the houses that fringe it are large and substantial, and are inhabited by well-to-do people. Such cottages as still remain are neat in themselves, and possess nice little well-kept front gardens, in which may be found, along with a host of other appropriate things, those universal favourites, the rose and the honeysuckle, revelling in luxuriant growth. Our local horticultural society has done much to stimulate small holders in this direction by offering prizes for the best kept gardens. The roadway is divided from the ample footpath by a broad margin of grass, on which stood a beautiful row of lime trees, which, judging from their appearance, must have been planted some fifty or sixty years ago. Apart from their stately look, these afforded a grateful shade to pedestrians. But now, I am sorry to say, they must be numbered with things of the past, the local board having within the last few weeks employed men to behead the whole of them some ten feet from the ground, leaving them hideous monuments of district mismanagement. After such vandalism as this, surely London wants a Haussmann, not only to rectify the blunders and shortcomings of times gone by, but to prevent such atrocities as that to which I have just alluded.—T. BAINES, *Southgate*.

How to keep Cats out of Town-Gardens.—Has anyone with a small garden in a densely-populated neighbourhood ever been troubled with cats? Has anyone had reason to observe that natural curiosity, that incarnate love of knowledge, which impels the feline race to search for it round the roots of freshly-planted specimens? Have finished beds borne witness to the infernal gambols *en clair de la lune?* I present a "perfect cure," or, what is better, prevention. The material is simple enough, and obtainable everywhere; it is wire-netting. But how to apply it? At first I had it fixed on the tops of the walls and fences, thus raising them four feet all round the premises. Well, this answered for about an hour and a half, after which interval it was of no service whatever, apparently an attraction. Tabbies and tortoiseshells, tailed and tailless alike, seemed to approve of and fall

into the arrangement readily. They also brought friends to see the novelty. Now, the grandest discoveries have ever been of the simplest character. By simply taking down the wire-netting and fastening it flat on the top of the wall or fence, like a coping, projecting two feet on each side—if it bend down by its own weight and form an angle so much the better—I have for now six months been able to defy all the assaults of the enemy. I have seen many a grimalkin, perched in a tree, with wistful eyes "view the landscape o'er," but never yet has one managed to cross. It might be asked, Why have the wire on your own side too? Stop a bit; the foe may get in through a gate or window carelessly left open, and then, if anyone is fond of what our neighbours call *le sport*, if he admires feats of agility, he will wish to keep the intruder from getting out immediately. Let him close the gate and begin. To watch the pursued puss run or rather fly along up in the angle A, is a delight hardly to be surpassed, except by watching two! To see "the affrighted foe race round the walls and run to each avenue," will be vengeance enough without the whip,

with which, however, it is well to be armed, as I have found a cat in despair face about and attack dogs and children. Let this simple remedy be tried. I will answer for it that the angle B will keep any cat from getting in, and the angle A from getting out, until you choose to let it.—*Penumbra*, in "*Journal of Horticulture*".

TOWN TREES.

The trees best fitted for street and square planting about large towns, where smoke and dust abound, are such as will look clean, shining, fresh, and flourishing, after every shower of rain. Their foliage, too, should be of beautiful shape, and change to various tints in autumn, mostly falling off all at once, instead of causing a continual litter on the occurrence of every puff of wind for weeks. They should, moreover, be such as will form a nice, pleasant, and variable summer shade, admitting freely light and air in winter. Nothing adds so much to the adornment of towns or villages as judicious tree planting by the side-walks of streets, waste corners, village greens, &c. Such embellishments give to cities an air of verdant beauty, which never fails to interest the casual visitor, and they comfort the inhabitants by their welcome shade during the heat of summer. But independently of the interest which they excite when budding out in the spring, in blossom, or in fruit, they soften and, in a measure, regulate the atmosphere, abating its excessive heat in summer and partially breaking heavy gales and storms.

The following, to some extent, embody these desiderata, and are well-fitted for planting in large towns where much smoke, dust, fog, and darkness prevail, viz.:—*Platanus orientalis*, *P. acerifolia*, *P. hispanica*, *P. occidentalis*, *P. pyramidalis*, and *P. laciniata*; *Liquidambar*; *Saisburya*; *Populus alba* and *P. canadensis*; *Weeping Willow*; *Horse-Chestnut*; *Scarlet-Chestnut*; variegated *Sycamore*; *Acer macrophyllum*, *A. platanoides*; and *A. barbatum*; *Lilacs*, on account of their early buds and blossoms; *Laburnums*; double and single scarlet and white Thorns; and *Syringas*. The common *Robinia* and its varieties also make good town trees.

JAMES BARNES.

SOILS, MANURES, &c.

SOIL FOR POTTING.

ONE of the most common and fatal errors into which the inexperienced fall is that of making choice of inert and finely pulverised soil for potting with. This and insufficient drainage are more disastrous to pot plants than any other two points of culture that can be named. To pot plants in common garden soil which is generally destitute of fibrous matter, and at the same time to neglect thorough drainage, is the shortest and surest way of reducing a plant, however hardy and vigorous, to a state of inaction and premature decline. Such soil is destitute to a great extent of what forms the food of plants. Were this its only fault, it might be remedied by the application of stimulants in a liquid form; but the principal want or error lies in its mechanical condition being at variance with the requirements of a healthy pot plant. What is required is organic or turfey matter, which in its gradual decomposition affords food to the plant, and at the same time forms a root medium, which freely admits the wholesome influence of the atmosphere, and has the power of absorbing therefrom the essential gases so necessary to the well-being of plant life. A plant potted in finely pulverised soil, or rather dust, entirely destitute of fibrous particles, finds itself, especially after frequent waterings, in a close hardened medium. If young roots are ever formed in a healthy condition they are most difficult to be kept alive, if that be at all possible under such circumstances. Such a body of soil, especially if watered with water in which there is a sediment, soon becomes solid, and no tender plant can thrive in it. The soil most suitable for the growth of plants in pots should contain a large proportion of decomposing fibrous matter, such as the roots and herbage which are common to the surface of old pastures. The fibrous matter which such soil contains not only presents in its gradual decomposition the constituent elements which form the chief food of plants, but prevents at the same time the soil from becoming compressed and soured. Such soil should be chopped up or teased with the hand without removing the fibre. Sifting should never be had recourse to, except when it is to be used for potting young things in very small pots; and even then, instead of separating the fibre from

the finer soil, it should be all passed through the sieve, simply for the purpose of breaking it up and making it fit for going into small pots without taking the fibre out of it. Soil of this fibry description—fresh and open—should form the chief of mixtures for potting with, and is in itself very nutritious. Manorial substances, such as leaf mould and rotten dung, can be added to such a staple with safety in the case of gross-feeding plants. The amount of sand added to it must be decided by the character of the roots which various plants make. Heaths, azaleas, and the generality of New Holland plants, which make fine hair-like roots, require a more sandy soil than others; while such as oranges and camellias, which make strong crow-quill like roots, demand a very moderate admixture of sand. The former plants, too, require more of a peaty than a loamy or calcareous soil; but in all cases there should be a large amount of fibrous material. In using such soil, it should always be inclined to the dry side, as, when used wet, it is apt to become compressed and ill-conditioned. A.

House Sewerage.—The distressing illness of his Royal Highness the Prince of Wales has aroused the public to a sense of the danger of having their houses provided with fever-traps. I will explain how I turn the fever-trap into a harmless, useful adjunct to my garden. I have the cesspool, or dead-well, dug as far from the house and well as the limits of my garden will allow; the top of the cesspool is covered loosely with a stone, leaving space for any gas there may be to escape. As soon as the gardener comes to his work, he sprinkles earth upon the previous twenty-four hours' accumulation, sometimes adding a little lime. When he requires any manure for the garden, he goes to the dead-well and takes from thence a highly fertilizing and inodorous compound, equal in every way and similar to the A B C, containing, indeed, some accessories of fertilization that are eliminated in the A B C process. I utilized the sewage from the house and stable in the manner I have described for three years whilst in Hampshire, and am doing the same now in Surrey. The top of the well being pretty open, no gas can accumulate. The application of earth and lime entirely deodorises the matter, by the aid of which I grow roots and cattle-melons of enormous size.—*Auticus.*

Earth-Closets for the Garden.—Ten years ago, and during the time of the formation of the new gardens here, no expense whatever was spared with a view to make, everything as complete and comfortable for the work people as it could possibly be made; and the accommodation then provided leads me to speak of the water-closets. On account of these being used by a number of people, say from thirty to fifty, for a period of ten years, they were a continual source of annoyance, being every now and then out of order, and they emptied themselves into a cesspool, which overflowed in a disagreeable way in the sunk fence which cut off the gardens from the park. About twelve months ago, therefore, when, from the severity of the winter, pipes were bursting in all directions, I resolved to try the dry-earth closet-system, as we had come to a complete breakdown with our water-closet plan. The site chosen for our new earth-closet was in our rubbish-yard, where there always abundance of earth thrown out from the potting-shed, and here we erected our closet, or I should rather say, closet and shed combined; the dimensions of which are thirty feet long, eight feet wide, and eight feet high; at one end we fixed the closet, which occupies six feet, the remaining twenty-four forming an open shed for the storage of deodorised faeces when mixed with earth. The closet is entirely shut off from the mixing or storage department; the faeces bin being curtained over by a wooden flap, which is hooked up every morning by the person whose duty it is to cover with earth the soil which has been deposited during the previous night and day. Once a week the bin is cleared out and thrown back to the end of the shed, where it remains until wanted for manorial purposes. The system has now been used for nearly a year, and the quantity of fertilised earth thrown back to the end of the shed does not yet exceed two ordinary cartloads; and this, I believe, might again be used as a deodoriser in cases where earth was not so conveniently to be had as it is with us. This closet, although situated within twelve feet of a much frequented walk, hidden only by a few bushes, gives as little indication of its presence as though it were a hundred miles away. Having no machinery, it does not require the earth, to be either dry or sifted, but used just as it comes from the potting shed. In this case earth has most advantageously superseded water, and peat-charcoal will doubtless soon effectually supersede earth for deodorising purposes, not only for closets generally, but also for the sewage of large towns. Hitherto, even our best engineers seem to have but one idea with regard to the treatment of the sewage question, viz., the erection of enormously expensive steam-engines,

and the purchase of hundreds of acres of land upon which to pump the sewage. For this purpose a town near to where I am now writing was advised by its engineer to spend over £200,000, but the authorities, before committing themselves, asked what this £200,000 would give them? “Only an experiment,” was all the answer which could be obtained. Therefore, until something more tangible shall have been fixed upon, better perhaps let the pestiferous ammonia continue to flow into our rivers as it has hitherto done. Must another Watt or another Stephenson be created before the sewage difficulty can be solved?—WILLIAM MILLER, *Combe Abbey Gardens, near Coventry.*—[The dry-earth system deserves adoption in every garden.—ED.]

PLANT MATERIAL FOR PAPER.

At a late meeting of the Society of Arts a paper was read by Mr. R. Johnson, on “Esparto,” including practical remarks on the nature, cultivation, past history, and future prospects of the plant; also, a demonstration of the importance to the paper-making trade of prompt and vigorous measures for its preservation. Mr. Johnson commenced by remarking that esparto, or Spanish grass, was at present almost universally used in the paper trade; that most of our leading journals and periodicals were printed on paper made from this material; the imports into this country having increased from 50 tons in 1856, to over 100,000 tons in 1870, and exceeded 130,000 tons in eleven months of the present year: the value having also advanced from £4 a ton in 1858 to the sum of £10, the current price last year. After alluding to the knowledge possessed by the ancients of the value of the plant, its botanical classification, and its appearance and growth, Mr. Johnson said that the best climate for its production was on the sea-coast at moderate altitudes. Here it was fine, short, even esparto, so much prized by paper-makers. In the interior this prime sort will form one-half and sometimes no more than one-fifth of the whole. A sandy or thinly-coated stony soil is suitable, but the grass never reaches perfection in clay. The most suitable zone runs from 32° to 41°, including the southern part of Spain and northern rivers of Africa. When fully ripe in the autumn the leaf or annual growth is pulled off the perennial stock, or *atoccha*, which is left uninjured in the ground, ready to send forth shoots in November or December. The operation of harvesting should always take place in dry weather. Immense waste has taken place owing to want of care in managing the crop. It is estimated that at the time it was first used for paper-making the quantity in Spain amounted to about 220,000 tons; but since then large quantities have been allowed to rot in the ground, or have been grubbed up to make room for cereals or to serve as thatch. When the sudden demand took place, instead of going back to dormant lands in the interior, the collectors called on the coast for double crops, which had a most deteriorating influence on the crop, and insomuch districts led to the complete extinction of the plant, not that double cropping in itself was injurious, if carefully and judiciously done, but the harm was caused by the host of careless harvesters. Careful cultivation is essentially necessary for the growth and preservation of the plant, which otherwise will vanish away. Mr. Johnson then gave some practical suggestions on the best mode of preserving and propagating esparto from personal experience, including observations on raising the plant from the seed, the time of sowing, mode of transplanting, and the method of burning. The latter mode consisted in firing the old *atocchas* or roots, by which means the soil is cleansed, and stimulating the plant, it being believed that the *atocchas* so produced are quite as healthy and long-lived as the seedlings. This mode can only be applied to old lands; and with reference to new lands, the sowing process is to be preferred to transplanting. The process of burning has several advantages: it destroys the old worn-out *atochas*, it cleans the roots of the young plant, and leaves in the soil an efficient manure to sustain and stimulate the young plant. As previously stated, the amount of esparto formerly grown was estimated at 220,000 tons, but at present it is doubtful whether more than 150,000 tons could be mustered.

Mr. Hyde Clarke suggested that the growth of esparto grass should be encouraged in Asia Minor, where the climate was suitable, and no doubt every facility would be afforded by the Ottoman Government, as it had already done for cotton, and suggested that the Council of the Society of Arts should take the matter up as one of great importance.

Other speakers followed, and from the general observations made it appeared that as it took about fifteen years to bring the plant to maturity, the establishment of new esparto growing districts would not bring the relief to the paper trade which was required in providing an immediate supply of some cheap and good material. The fibro of wood had been tried, but had proved a failure, and it was added that it must be regarded simply in the light of adulteration.

THE HOUSEHOLD.

The Egg Plant.—In America the fruit of the egg plant grows as large as a moderate-sized gourd, and it is there a delicious vegetable. We might try them in pits and frames in summer, planting them out on a gentle hotbed, and giving them a very sunny position. Many say they do not understand how others can like the egg plant. We can: cooking is everything. The best directions are given in the *American Agriculturist* by one of its house-keeping readers. Cut the fruit across into thin slices, say a quarter of an inch thick; salt and lay these together over-night; in the morning take them from the brine, and sprinkle finely-powdered cracker over both sides of the slices; then fry brown (not black), in just enough fat to keep them from sticking to the griddle. Some use Indian meal, instead of cracker, but the cracker is best. We eat them thus cooked, and esteem them a really cheap delicacy, though we once thought them poor stuff. A subscriber at our elbow says:—"Cut them into slices nearly half an inch thick; sprinkle on salt; lay them together with a light weight on the top; in the morning drain from the brine, roll in flour, and fry in butter, and they can't be beat."

Russian way of Dressing Cucumbers.—The cucumber is sliced in the usual way. A few celery leaves must be previously chopped very fine, and mixed with a good quantity of the best oil, sufficient vinegar, pepper, and salt being added to give it the proper piquancy. This mode of dressing cucumber makes an agreeable change in summer to many plates. As the flavour of celery is very powerful, it is not required in great quantity.

The Miniature Savoy Cabbage.—This has been one of the most useful of our green vegetables during the recent severe frost. The seed was sown March 24th, and the plants were put out in the usual way when forward enough. They have formed compact hearts the size of a tea-cup to that of a breakfast-cup. Those who doat on solid savoysas big as drums would despise these little things; but they suit our taste well, because elegant, tender, and delicate; whereas gigantic savoys are inelegant, tough, and coarse, no matter how skilfully they may be cooked. The miniature savoy bears all the same relation to the giant proper as the elegant and delicate does to the coarse "colossal," bears to the cabbage proper; and these two little treasures of the kitchen are equally unprofitable if judged by mere dead weight or bulk of produce. We have received the miniature savoy under a variety of names, such as "Tom Thumb," "Little Pixie," and "New Early Green Dwarf," but there appears to be only one stock of it; all events, we can find no difference in our several samples to justify difference of name.—S. H., in "*Gardener's Magazine*."

Colorado Produce.—Grace Greenwood, in a letter to the *New York Times*, giving account of her autumn fare, writes:—"The buildings devoted to farm-witches and mineral waters are well filled, and were to me by far the most interesting departments. I had seen elsewhere some Brothbergian vegetables. Think of early potatoes, sound and sweet to the core, weighing 6 lbs. apiece! Consider a turnip weighing 22 lbs! Bring your mind up to a cabbage of 50 lbs! Shudder before an awful blood-beet of 16 lbs., and make obeisance before a pumpkin actually weighing 130 lbs.! I really reverence that power which can contrive such a profusion of sunshine. I would make a pulpit of it, or the platform of Women's Rights. One could hardly conceive of another sacred or dignified use. Think of Spanish cucumbers by the yard, and other sacred or dignified use. Think of Spanish cucumbers by the yard, and wheat, oats, and barley more than six feet tall. You need not be surprised to have a Colorado friend write to you from his ranch in this wise:—sitting in the cool shade of a stalk of barley growing by my door!"

To Peel Potatoes.—One party argues that it is necessary to remove the skins before boiling, to permit hurtful gases to escape, and to allow the water to enter the potato and cool it down. At the gases, there need be no fear. Good sound potatoes contain no gas that is not easily released, or opening a way for the water to readily enter the potato, when it is desired to keep it out as much as practicable. Potatoes contain water enough in their composition to answer all purposes for cooking, as is seen in the moist substance of a baked potato, which is generally conceded by almost everybody to be better than the dried article. It is stated that a pound of the substance of this vegetable contains more than a quart of a pound of watery juice, to two or two and a half ounces of starch. In cooking the water is absorbed by the starch grains, which swell and often burst the cells. The albumen congeals and forms irregular fibres. There is, then, no necessity for letting water enter the potato through openings made in the skin. Even if potatoes boiled whole were no better than those peeled before cooking, economy would decide in favor of the former practice. Part of the substance is necessarily wasted by peeling, and it takes more time than after cooking. They will keep hot much longer if the skins are left until used at the table; but it is generally thought preferable to wash and otherwise prepare them before placing them before guests.—*American Paper*.

Vegetables in London Dining-Rooms.—It is my fortune to dine occasionally in what are considered the best London dining-rooms, in which the meat is generally irreproachable, the wines drinkable, the beer perfection; but I hardly ever get any vegetable that is edible. Nothing but an extreme weakness for vegetable could have induced me to face it as served at Simpson's, the Rainbow, and the like, during the past year. Truly it is sometimes—though it is sometimes very small—not only the size, but the quality of what is served up to an adult Christian, do I complain of, nor its price, but the way in which decimated and blackened and dirty "sticks" are served up among the better ones. It is bad enough to have it poor and thin; it is bad enough to have but very little of it even in that state; but it is intolerable that the cook should not bestow on the removal of the decay that arises in the conveyance of this vegetable from the market to the dining-room. Paris is the only place where I am lying in state in Covent Garden, as much attention is taken here in assuring him that he is fit for the lettuces—leathery, hard, and dirty even in the month of May—they are only fit to throw to rabbits that have good teeth and get plenty of exercise. There is no more reason why they should be so than that we should have crab apples instead of Ribston pippins. But the radishes, the radishes! Unless you readers are all unhappy wreaths who had run short of provisions in traversing some of the most crowded and tried many a bitterly-disappointing root, I could hope to give them an idea of what a long, spongy, fibrous, acrid, stinging root that do duty for radishes in London dining-rooms. These have no more in

common with the delicate little masses of crisp succulence which well-grown and timely-gathered radishes present, than a wiry old swede turnip, ready to start for seed, with a tender garden turnip gathered a few months after its birth. No doubt the majority of persons who frequent such places have no idea of a better radish, or we should not have these rats-tails disgracing the civilization and culture of the British Empire. A knight may be bitten in the nose by the creatures one piles as they munch these masses of thready and bitter tissue, but it is all the time very bad for their digestion and teeth, as well as offensive to the eyes and ears of sensitive person.—V., in "*Field*."

Frijoles.—From the town of Taos, in the extreme north, to the Isthmus of Tehuantepec in the south, there is not a Mexican cottage, however humble, without frijoles are not cooked and eaten at least once, and often twice, during every day—for hours, and that not without there are plenty of other edible substances to be had, such as, for instance, beans, yams, the sweet potato, the manioc root, and an endless list of other roots and fruits, available for food. The frijol is nothing more than what we are accustomed to call a "kidney bean," and known to our French neighbours as the "haricot." It is true, the kidney eaten in Mexico are somewhat different from either our scarlet-rummers or dwarfs. But they are only varieties of the same plant; differing with the French having more of the colour of their outside, and differing in their respective substance of flavour. The frijol is eaten in Mexico—that mostly met with on the *table-lands*—is a small black bean (*phaseolus Hermannii*)—while another sort of a brownish-red colour is cultivated on low-lying tropical lands of the coast. The latter has the reputation of being a superior kind—considered as an article of food. Frijoles in Mexico are not eaten, as with us, pods and all, in their green unripe state. Before coming into the kitchen they are ripe, and shelled clean of their capsules. Short, they are said to be Mexican beans, and are first boiled, then broken, and then boiled again soft. To effect this a little lye is sometimes thrown into the earthen pot in which the boiling is done—just as in preparing Indian corn for *farritas*. When well boiled the beans are next submitted to a simmering process, being mixed with a little lard and some chili pepper—not the dry, pulverised dust, known to us as "cayenne," but the green, pulpy pod of the capsicum, crushed between the two beans. This is the *lado de frijol*. In addition to the lard and capsicum, frijoles are sometimes served with just a touch of oil, which is to be parboiled, thus producing a dish that, for piquancy, is not easily excelled, and all things considered, can scarcely be equalled in cheapness. If introduced into England, and *naturalised* in our cottage homes, it would prove a real blessing—cheaper than even dry bread and cheese, and far more palatable than a scrap of badly-cured American bacon—the only article of so-called flesh-meat which labourers have usually the privilege of tasting. The frijol is well known in the climate of England, as well as in that of Mexico; indeed, it is grown here, thrice as luxuriantly as in the midland of England, and is here called *lado*—or, or the still more prolific "dwarf." And capsicums can also be cultivated in any quantity, while onions are grown everywhere. Lard is not dear—at all events, it is the cheapest of culinary aids—and in the cooking of frijoles only a very small quantity is required. This dish, of course, calls for an accompaniment of bread, just as any other stevy soup; and in Mexico it is eaten with an *unhewn* *cuenco*—the latter, as is well known, being torn into pieces, and employed as a scoop or spoon, that is swallowed with each mouthful of the stew. *Food Journal*.

Salads and Salad Making.—The art of making a salad is one of those attributes with which every person credits himself, whereas in truth it is possessed by a very small number of the gifted few. The English, as a rule, are crude and coarse in their salads as in their cooking. A hard, overgrown, coarse lettuce, some tough, pungent, fibrous or woolly radishes, a few onions, and a bunch of turnips, plus a dash of mustard, with some mayonnaise, pepper-mustard, and a few drops of oil, and you have the *salad* of a schoolboy. We would as soon groan with *Nichchabazeeza* or turn ruminant at once. There are salads and salmades, graduating from the simple repast to the most elaborately prepared viands, culminating in the glories of delicious lobster salad. Even the simplest form of salad admits of preparation on several different principles. Our own method is diametrically opposed to the common method, which our founders give it a trial; they can return to the system if they do not like it; but we will now give the system exemplified by the following directions for a lettuce salad: Wash and pick two or three well-blended lettuces, taking off the outer leaves; then dry them well in an open wicker-work basket made with a handle, swinging it to and fro at arm's length to get rid of the water, and cut them across a few times (not very small); mix a saltspoonful of vinegar into a tablespoonful of vinegar until dissolved, and pour it over the salad, adding half a saltspoonful more vinegar to suit the palate if desired; then add a few drops of oil, and mix well; then add a few drops of pepper-mustard, and mix again; then add a few drops of English pepper, the *pepper* of a schoolboy. We would as soon groan with *Nichchabazeeza* or turn ruminant at once. Lettuce flowers are often added, which give a far more pleasant zest than cayenne pepper; watercress, purslane, or mustard-and-cress may be introduced if agreeable. In this plan the vinegar is first added to the washed salad, and a large amount of stirring is required to diffuse the oil, so that the salad should not taste oily. The system is the same, and the results the same, as that adopted by all the rest of Europe. *Neapolitan* is the system that is appreciated by few *cognoscenti* in this country)—the lettuce, we say again, should not be washed if the process can be dispensed with, but if necessary each leaf should be separately wiped, cut up, and put in the bowl. If you must wash your salad, you cannot be too careful in draining all the water from it, for every drop of water left in a salad tends to spoil it, and the loss of a large amount of water is a loss of a large part of the salad. *French* oil is also necessary in taking the salad, so as to exclude every heat that is the least tainted or discoloured. It is a great mistake to cut up lettuces and endives into fine threads; this operation at once destroys the freshness, taste, and character of the dish. Of course I do not mean that coles lettuces simply split in two should be made into a salad; but there is a happy medium, which is always best in most things. Besides, it is by no means necessary to wash the heads of the best salads; the coarsest lettuce, which is all we have in winter, is well suited to the coarsest lettuce—the *laitue romaine*, which is well *pommée*—is by far preferable. This should be cut into quarters like an orange, and no more. Now add the oil, and stir until each portion is covered with a thin film; then stir together in the salad-spoon the salt, vinegar (which should be real French), pepper, and a little powdered white sugar, without which no good salad was ever made. Add these to the salad, and mix well, and add the sides of the salad, and the oil, with or instead of common pepper. The remotest suspicion of scalded onion or shallot may be added—not large slices, which will make you odorous for a week—and other vegetables, as beetroot, cresses, lamb's lettuce, &c., may be introduced; but let the grand principle still remain, namely, that the salad be dry, and that the oil be universally diffused before the vinegar is added. By so doing salad is never greasy, and the pepper and other adjuncts preserve their true flavor, not being obscured by the vinegar. So much for the preparation of a simple salad.—*The G. C.*, in "*Queen*."

THE FLOWER-GARDEN.

HERBACEOUS PLANTS FOR EXHIBITION.

ABOUT two years ago the Royal Botanic Society judiciously offered a prize for twenty-four hardy herbaceous plants, and fearing that there might be little or no competition for it, I did my best to back the Society's efforts, in what I thought to be a good direction, by sending a group, as I was anxious the class should not fail to the ground. I am, therefore, pleased to find that the Royal Horticultural Society has taken the same matter in hand, and that they offer many prizes for plants of this kind, viz.:—

May 15th. 12 Hardy Perennials in 12-inch pots.
June 10th. 6 Peonies in pots.
July 17th. 12 Hardy Perennials in 12-inch pots.
" " 6 Phloxes in 12-inch pots.
" " 6 Penstemons in 8-inch pots.
" " 6 Phloxes in 10-inch pots.
" " 6 Lobelia in 8-inch pots.

Aug. 21st. 12 Hardy Perennials in 12-inch pots.

Besides cut blooms of Peonies, Phloxes, Pyrethrums, &c.

In order, therefore, that these prizes may be well contested, I have made out a list of such plants as will constitute the basis of a good collection, from which specimens for exhibition may be selected. The names are those under which they are generally known, and they represent plants which flower from April to September, and which are suitable for pots, viz.:—

<i>Alyssum orientale</i>	<i>Hesperis matronalis</i>	<i>P. Bonheur</i>
<i>A. saxatile compactum</i>	<i>purpureo-plena</i>	<i>P. Princess Troubetzkoy</i>
<i>Anemone alba</i>	<i>Iberis correaefolia</i>	<i>P. Purple Prince</i>
<i>Anthemis Liliastrium</i>	<i>I. Garrettiana</i>	<i>P. Roi des Roses</i>
<i>Aquilegia carulea</i>	<i>Iris nudicaulis</i>	<i>P. Roi des Bianche</i>
<i>Asteria cephaea</i>	<i>I. germanica</i>	<i>P. Roi des Feuilles</i>
<i>Aubrieta deltoidea</i>	<i>I. g. Purpurea</i>	<i>P. Amabile</i>
<i>A. grandiflora</i>	<i>I. g. grandiflora</i>	<i>P. Dame Blanche</i>
<i>Aethionema mem-branaceum</i>	<i>I. g. jacquensis</i>	<i>P. Ninon</i>
<i>Betonica grandiflora</i>	<i>I. g. Duchesne de Nemours</i>	<i>P. Virgo Marie</i>
<i>stricta</i>	<i>I. g. Lilianae</i>	<i>P. Mons. Ingres</i>
<i>Calystegia pubescens</i>	<i>I. g. pallida</i>	<i>P. Souvenir de Soltzmont</i>
<i>dore pleno</i>	<i>I. g. Versailles</i>	<i>Polygonatum multiflorum</i>
<i>Campanula carpatica</i>	<i>Liatris spicata</i>	<i>Polygonatia virginiana</i>
<i>C. carpathica alba</i>	<i>Lupinus polyphyllus</i>	<i>Potentilla Louis Van Houtte</i>
<i>C. coronata</i>	<i>L. polyphyllus albus</i>	<i>P. Phœbe</i>
<i>C. coronata cerulea</i>	<i>Linum flavum</i>	<i>P. Le Danté</i>
<i>C. grandis</i>	<i>L. campanulatum</i>	<i>P. D. Amy</i>
<i>C. petraea</i>	<i>Nierembergia rivilaris</i>	<i>Primula coriifolia</i>
<i>C. plena</i>	<i>Oenothera fruticosa</i>	<i>P. amara</i>
<i>C. p. albo-plena</i>	<i>G. Fræseri</i>	<i>P. nivalis</i>
<i>C. p. maxima</i>	<i>Onosma taurica</i>	<i>Pyrethrum floribundum</i>
<i>C. Trachelium albo-plena</i>	<i>Paeonia tenuifolia flore pleno</i>	<i>plenum</i>
<i>C. turbinata</i>	<i>P. officinalis rubra</i>	<i>P. fulgens plenissimum</i>
<i>C. turbinata grandiflora</i>	<i>plena</i>	<i>P. Grandiflora</i>
<i>C. umbellata</i>	<i>P. officinalis Alliacea</i>	<i>P. unibracteatum plenum</i>
<i>Centauraea montana</i>	<i>P. Standard de Gaud</i>	<i>P. Iveryanum</i>
<i>Convallaria majalis</i>	<i>P. Eugenie Verteuil</i>	<i>P. Lady Blanche</i>
<i>C. majalis striata</i>	<i>P. Festive maxima</i>	<i>P. Madame Munier</i>
<i>Coreopsis lanceolata</i>	<i>P. Jenne d'Arc</i>	<i>P. Monsieur Barral</i>
<i>Delphinium Barlowii</i>	<i>P. Madame Calot</i>	<i>P. niveum plenum</i>
<i>versicolor</i>	<i>P. Mademoiselle Furtado</i>	<i>P. Rev. J. D. Sedgwick</i>
<i>D. M. Bihani</i>	<i>P. Modeste Guerrini</i>	<i>P. reichenbachianum</i>
<i>D. Madame H.</i>	<i>P. Nelly Moser</i>	<i>P. subulatum</i>
<i>Jacotat</i>	<i>P. Reine des Roses</i>	<i>Spiraea palmaria</i>
<i>D. Keteleeriai</i>	<i>Pentstemon glaber</i>	<i>Statice latifolia</i>
<i>Bella Donna</i>	<i>P. procera</i>	<i>S. latifolia alba</i>
<i>D. coronata</i>	<i>Phlox divaricata</i>	<i>Stemastis speciosus</i>
<i>D. formosum</i>	<i>P. Nelsonii</i>	<i>Tritoma Uvaria glaucescens</i>
<i>D. Hemerocallis</i>	<i>P. pubulata</i>	<i>T. grandis</i>
<i>D. Madonnae</i>	<i>P. Annae Boreale</i>	<i>Trollius napellifolius</i>
<i>D. magnum</i>	<i>P. Come de Lambertye</i>	<i>Tradescantia virginiana alba</i>
<i>D. nigrum</i>	<i>P. Edith</i>	<i>T. virginica azurea</i>
<i>D. Niles Bourgeois</i>	<i>P. George Ville</i>	<i>T. v. rubra</i>
<i>D. Nahamah</i>	<i>P. Lucien Tissarand</i>	<i>Trillium grandiflorum</i>
<i>Dilectia spectabilis</i>	<i>P. Madame Cannert</i>	<i>Urtica dioica</i>
<i>Doronicum austriacum</i>	<i>P. M. Logan</i>	<i>V. verbenacea</i>
<i>Gaillardia lobi</i>	<i>P. Mr. Malec</i>	<i>V. caucasica</i>
<i>G. pulcherrima</i>	<i>M. M. Loggan</i>	<i>V. multifida</i>
<i>Geranium pratense fl. pl.</i>	<i>H. M. Edmond André</i>	<i>V. maritima alba</i>
<i>G. sylvaticum fl. pl.</i>	<i>H. P. Plus IX</i>	<i>V. Guthriana</i>
<i>Hesperis matronalis</i>	<i>H. P. Professor Koch</i>	
<i>albo-plena</i>		
<i>Tooling.</i>		

THOMAS BROWN.

Wall Plants.—Walls afford the best positions for many half-hardy subjects that do but little good in the open air without their aid; walls, if well-covered and carefully attended to, are among the most useful aids to a garden. Well covered in every part with good climbers, the stiffest and most awkwardly placed of wall surfaces becomes a thing of beauty, and may afford interest and flowers at all seasons, from that of the wintry bloom of the clear yellow Jasminum nudiflorum to the heats of early autumn, when the fine Clematis become masses of flower. The climate of the British isle is so much varied that plants which grow as standards in the south may require a wall in the north; in the south we may have walls covered with

sweet Verbena, and even with Pittosporum. In the south we grow the fig as a standard; in the north it can barely exist with a wall. But in all parts we may make good use of every particle of flower-garden wall, no matter what its texture, aspect, or height. The first and most important consideration in the covering of garden walls is the selection of the plants. But even where these are well selected, there is frequently a mistake made in the training, by paying no proper attention to train the tree over the wall in a spreading manner, but, on the contrary, allowing it to run "up to a head," so to speak, each plant being topheavy, and narrow and naked at the bottom. Instead of taking one good specimen and making it cover a full portion of the wall, people plant them rather thickly, and then keep continually clipping away the luxuriant shoots that ought to widely furnish the wall. The best shoots should be taken out in a fan-like manner, so as to cover the wall to the very ground. In training them out, in fact, the strongest shoots should be taken to the right and left, perhaps to send up straight shoots themselves. The object should be to keep every part of the wall covered, the centre of the tree as much so as the top of the wall, and in fact all parts equally. When once the trainer is impressed with the desirability of covering the wall equally in all its parts, he will have no difficulty in doing so. A great point is to make the strong-growing kinds cover a great deal of surface. Confine them to a small space, and you must cut them away fortnightly, or allow them to run disgracefully wild.—V. G. R.

DIMORPHANTHUS MANDSCHURICUS.

This is one of the noblest shrubs for a long time introduced to our gardens, and one which especially commends itself to us at a time when plants of noble port and foliage are beginning to be more generally esteemed. It is a magnificent hardy shrub, of erect habit, with very large, much-divided, spiny leaves, which greatly resemble those of the Angelica tree of North America, and in this

Dimorphanthus mandschuricus.—Hardy deciduous shrub section.

country attaining a height of six feet to ten feet, which it will probably much exceed when well established in favourable positions. It is certainly the most remarkable fine-folaged shrub that has been introduced into our gardens for years, and is therefore of the highest importance for the sub-tropical garden. As to its treatment, it seems to thrive with the greatest vigour in a well-drained deep loam, and would grow well in ordinary garden soil. As to position, isolation in some sheltered but sunny spot will show it to great advantage; but it may also be grouped with like subjects, always allowing space for the spread of its great leaves.

The Earliest Spring Flowers.—Can you name a few of the very earliest spring flowers that would bloom well? I leave my garden early in April for, among many others, mostly those that bloom very early. J. C. [in the following] will doubtless answer me fully with his various nigella and others; Rossini violet; Czar violet; Hepaticæ blue and pink, single and double; Myosotis diffracta; Arabis alpina; Aubrieta grandiflora; Blue pansy; Erica blanda; Saxifraga oppositifolia; Primrose, double lilac, do. white, do. purple; Daisy, white, Aucuba-leaved daisy; Iris, dwarf early; Lamium maculatum; Tussilago farfara; Dwarf wallflower, Belvoir var.; Oxlips, improved; Winter Aconite; Snowdrop; Scottia bifolia; S. sibirica; S. præco; Crocus; Double violet; Hyacinth; Anemone; Tulip; and Daffodil.—W. IX, 22, *Bittern.*

VARIEGATED PELARGONIUMS.

THESE having become great favourites for the decoration of our flower-gardens in summer and for beautifying our conservatories in winter and spring, a few hints as to the best mode of successfully keeping them during the winter, and the most expeditious and safest way to propagate them in early spring, summer, and autumn, may prove useful. Growing all the best and rarest kinds, propagating thousands of them, and having myself raised many popular varieties, I will simply describe my own most successful practice. The variegated pelargonium is very impatient of dampness about its foliage and too much moisture at the root. It is therefore necessary at all times to guard against any extreme in either case, and particularly in the winter season. We will begin with the treatment of the plants in September, after they have been taken up from the flower beds or borders, and give our mode of treating them from that time till May, when they may be planted out in the open bed again. After that the only care they will require is such as need not be described here.

The soil most suitable is a nice, soft, yellowish loam, mixed with well-decomposed leaf-soil and clean river or Reigate sand. The pots the plants are to be grown in should at all times be perfectly clean, especially on the inside; for if dirty pots are used, when it becomes necessary to re-pot the plants, it will be found, on turning them out of the pots preparatory to shifting them into larger sizes, that large numbers of the most healthy roots are broken off and clinging to the old soil left on the sides of the pot; this must always be avoided. If the pot is perfectly clean when the plant is put into it, the ball will turn out entire by simply turning the plant upside down, and gently tapping the edge of the pot on the bench, and at the same time pressing the large piece of potsherd over the hole in the bottom of the pot with a small piece of wood, or with the forefinger. To drain the pots well should be borne in mind, and this is done by placing one piece of broken potsherd over the hole, then several other pieces above and around it; on the top of these should be placed some pieces of fibrous turf, to prevent the soil from trickling down amongst the drainage.

Having a quantity of soil mixed as above recommended, the pots clean and properly drained and the plants taken up from the beds, we will proceed with the work of potting them, after having reduced the quantity of foliage on each plant and just nipped off the points of their roots. It is always advisable to reduce the foliage before potting any plant taken up from the open ground. When this is done the roots will the more readily commence their work; when all the foliage is left on the plant more is required from the roots than they can perform. In reducing the foliage the leaf should not be cut off close to the stem; it is better to leave the foot-stalks of it entire, with a very small portion of the leaf still attached to it. The cut stalk will then gradually dry up and drop off of its own accord in a week or ten days' time, and the wound at the base of the stalk will be partly healed before it drops off, thus preventing the plant from suffering any injury; but when the leaf is cut off near the stem, it often happens that in decaying it taints the stem, so to speak, or at all events decay is conveyed to the stem of the plant, causing that to rot. Whenever this decay is observed it should at once be cut out clean with a sharp knife, else in a very short time it will eat its way through the stem of the plant. Many valuable plants are lost in this way.

In potting the plant hold it in the left hand, and continue shaking it whilst the soil is being thrown in about its roots with the right; this will cause the soil to settle itself nicely about its roots, but care must be taken not to have the plant placed too deep in the pot. As soon as the pot is filled up with soil give it a few taps on the bench, keeping the plant steady in its place in the centre of the pot by placing the thumb of each hand firm against the stem of the plant on each side. A little more soil should then be placed on the top; this must be pressed moderately firm with the thumb of each hand. If the soil is in a nice moist state, no water will be required for a week or ten days after the plants have been potted. After potting they should be placed in a rather close house or frame

for two or three weeks, by which time they will have commenced rooting freely, when they should be put in a more airy situation, and allowed to enjoy all the light of the season. They must be frequently looked over, and every little bit of decaying leaf must be at once removed. The plants may be kept in a situation similar to that recommended above till the first week in February, giving them but little water during the winter months; and whenever it is found necessary to water them it should always be done early in the morning, giving all the air possible afterwards, so that the atmosphere may become dry before shutting-up time; this will prevent the foliage from taking any harm during the night when the house is shut up close.

In the first week of February the plants should be all shaken out of the soil they have been growing in all through the winter; this should be done very carefully, the object being not to injure the roots. The same care must also be observed with regard to clean pots, and for this potting they should not be too large; the smaller the pot the better for the first potting. If the roots can be got into it without their being too much cramped or injured, so much the better; the roots will occupy the soil much quicker. The soil must be in a nice state of moisture. The plants will not require water for a week or more after potting, unless the weather should happen to be very frosty; when large fires have to be kept up, the plants will want water oftener. When water is given, it should be applied copiously, so that the whole of the ball of soil may be well soaked. It is always the safest and most proper plan to give a thorough good soaking when water is given, and the plants should never be watered before they actually want it. If proper care is taken in this way, the plants will soon begin growing away very freely, and will be ready for a shift into a larger pot by the third or fourth week in February. At this shift the soil recommended above may have a small quantity of well-decomposed cow manure (in a perfectly dry state) added to it. The same care must be observed with the soil as in the autumn or winter potting—it must not be too wet nor too dry. It should also be as nearly as possible of the same temperature as that the plants are growing in.

By the time the plants have been potted, a fortnight after the second shift, their roots will have reached the sides of the pots, and their tops will have commenced growing away freely. The work of propagation may now be commenced. The same mixture of soil as recommended for growing the plants will do for this purpose, only it will require more sand mixed with it to keep it porous; and the best plan is to strike the cuttings in single thumb or small sixty-sized pots, which must be clean and well drained. There should be about two inches of drainage put into each pot, which may consist of any of the following materials—viz., broken potsherds, oyster shells, or charcoal. In either case a portion of it must be broken into small pieces and placed on the top of the larger pieces, to keep the soil from trickling down amongst the drainage. The soil should then be placed in the pots, pressing it moderately firm, and filling the pot up to within half an inch of the rim; a quarter of an inch of good clean sand should then be laid over it and pressed pretty firm. This done, all will be ready for inserting the cuttings into them. For taking these off a very sharp knife should be used, so that the cutting may be taken off as clean as possible; and when the stock of any variety is small, and the object in view is to increase it as rapidly as possible (this is usually the case with new varieties), a little judgment is required in taking the cutting off so as to preserve the dormant eyes at that portion of the shoot next the cut. As soon as the young shoot has developed five leaves it may be taken off. The cutting should be separated from the plant a quarter of an inch below the position of the oldest leaf, and in trimming it a portion only of two oldest leaves should be cut away, leaving the leaf stalk entire. When the cuttings are ready a small dibber will be required for making a hole for the cutting in the centre of the pot. The dibber must be a little larger than the cutting, and quite flat at the end; the hole should be more than half an inch deep. The cutting may then be placed in the hole made by the dibber; the base of it should sit flat on the bottom of the hole. The space left between the sides of the hole and the cutting should be filled up with fine dry sand, which will trickle into every little crevice; and as soon as the cutting is secured by means

of two little hooks made out of deal or any other soft wood, the soil should be watered; this will consolidate the sand about the stem of the cutting, perfectly excluding the air from its base. The two hooks should be put in reverse, one pointing one way, and one the other. These should be hooked on to the leaf stalks, by which means the cutting will be kept perfectly firm in the pot—a very desirable object in the case of new and rare kinds.

After the cuttings have all been potted, they may be placed in a temperature of 60° or 65°, in a position as near the glass as possible; and if the pots can be plunged about half their depth in any sort of material having an average bottom-heat of 45° or 50°, they will strike much quicker. As soon as the cuttings are rooted, they should be shifted into three or four-inch pots, and kept in a nice growing temperature, and abundance of air must be given them on all favourable occasions. By the end of April these rooted cuttings may be decapitated, and the top of each put in, in the same way as described above. By this time also there will be two or more cuttings fit for taking off on the stump of each of the shoots from which the earliest were taken; these also may be taken off and propagated in the same way. The work of propagation may thus be carried on till the end of May or the second week in June; after this time the cuttings will strike with less trouble if pricked out in the open ground, fully exposed to the sunshine after the first week or ten days. Up to that time it is better to partially shade them by merely sticking small pieces of evergreens amongst them; this will prevent their foliage from being scorched by the sun. If it is desired to grow the plants on into large specimens for the greenhouse, they will require shifting into larger pots about once in six weeks or two months during the spring. During the whole of this time great care will be necessary in watering, and abundance of air must be given on all occasions. An average temperature of 50° is the most suitable for these beautiful plants during the winter months; as the spring advances an increase of temperature may take place, but it should never exceed 70° whilst the plants are grown under glass, and only reach that temperature during sunshine.—*J. Wills, F.R.H.S.*

NOTES ON HARDY FLOWERS.

AMONG tall Asters the best are *turbinellus* and *Noctis Angliae* *ruber*, and among dwarf ones *discolor* and *horizontalis*. [There are a good many other first-class kinds!—] *Astragalus Tragacantha* I never could succeed in growing from cuttings.—The great secret of growing *Anthriscus* well is to cut them back after flowering.—In some gardens it seems impossible to grow *Bulbocodium vernum*; I cannot grow it here. [We have noticed it thrive on deep bad clay soil!—] Does *Cotyledon umbilicus* generally grow in damp places? In this neighbourhood it is on the driest of old walls.—Who has *Crocus Cartwrightianus* in cultivation?—*Dracocephalum grandiflorum* is a most capricious plant. I have had it often, and never could keep it. [It ought to thrive in well-drained sandy loam, with plenty of moisture in summer.]—*Eryngium yuccafolium* is very similar to *E. bromeliifolium*, but it is certainly more hardy.—*Erythronium americanum* is not worth growing, for it utterly refuses to flower. I have had it for years, but have never seen a flower on it.—*Geranium argenteum* cannot be called hardy. [It is so in some places on the rock-garden in well-drained spots!—] *Gypsophila paniculata* is one of the most useful of flowers for nosegays with which I am acquainted.—Single shoots of *Hemerocallis fulva variegata* taken up in the spring and potted, form the best table plants I know of.—*Heucheras* are useful for filling up corners—as, for example, square corners of beds close to the gravel.—*Heracleum aurantiacum* becomes a dreadful weed if allowed to go to seed.—*Iberis juncunda* is very distinct and pretty. I think it is said to be very fine. It seems very hardy, but has not yet flowered with me.—*Iris susiana* is a grand fellow, but I never knew it remain more than one year. [Requires a pit to thrive and increase.]—*Lychnis Lagascae*, I think, should be treated as an annual, for it has a tendency to flower itself to death. [It is a good perennial on rocks.]—*Lysimachia Ephemera* should be grown in moist shady places.—*Mazus Pumilio* is not hardy.—*Meconopsis aculeata*. Who has this? In this country it is an annual, and grows from seed.—*Meum athamanticum* should not be allowed to flower.—*Mirabilis Jalapa*, I believe, is not taken up in the winter at Kew and Chelsea.—*Narcissus Bulbocodium* often entirely disappears, even where it had seemed most healthy. How is this?—*Nertera depressa*. Mr. Niven says the right name is *N. scoparioides*, and that it should

be grown under glass. I think he is right.—*Nierembergia rivularis* is not hardy with me.—*Omphalodes Luciliae*. Is this hardy?—*Onosma taurica* is very apt to die after proper flowering.—*Oxalis Valdiviana* is an annual, but takes good care to sow itself.—*Pachostethus communis* will live out of doors, but certainly not flower.—*Ramondia* should be always on the shady side of the rockwork.—*Saxifraga ligulata* is an excellent plant for the greenhouse in winter: it is scarcely hardy.—With respect to *Triteleia*, the whole plant smells of garlic, except the flower, which has a perfume like that of primrose.—*Tropaeolum polyphyllum* I consider to be one of the best of herbaceous plants, but it does not last long in flower.—*Tulipa Clusiana* is a very shy bloomer.—*Umbilicus spinosus* I think is quite hardy, but the slugs attack it most fearfully.—*Vesicaria* should be kept constantly free from seeds; old plants soon lose their beauty and die.—*Zapania nodiflora* perishes in hard winters.—*Colchicum chionense* I have had many years. It seldom flowers, and then the flower is not equal to that of *variegatum*; but it is worth growing for its curious narrow almost crimped leaves. It is very slow of increase.—In regard to *Fuchsias*: I believe that south of the Trent they are all hardy, except those of the *fulgens* section. A few miles from here I saw this year many of the fine greenhouse exhibition kinds which had stood out for years uninjured.—I don't think *Limnocharis* would long stand a winter, even in water that did not freeze.—*Vicia sylvatica* is a most lovely ornament of our woods, but I advise no one to take it into their garden.—*W. H. ELLACOMBE, Bilton Vicarage.*

THE TREE CARNATIONS.

THE reason why Tree Carnations are not to be seen more at this season of the year must be either that their culture is not properly understood, or that they are not sufficiently appreciated by the possessors of gardens. The latter reason seems to be to me impossible, for who is there that doesn't love a Carnation flower at this, the dullest of all seasons? The ungraciousness presented by their straggling habit of growth during the trim summer months may be supposed as another reason why they are not as they should be just now. In short, I think they are looked down upon in summer too much, and are apt to be shovelled aside for some other showy, trim-looking plant, in the same way as early forced roses are too often huddled into any out-of-the-way corner, to be chilled, parched, soddened, and tattered.

Tree Carnations, to be in perfection at this season, require attentive summer care, and I have always found that in-door care is the safest, and with it more heat (dry heat), with plenty of air. To have Carnation flowers all the year round in quantity, one must have a quantity of plants. Of course we could cut them every day in the year, not from the same set of plants, but from sets of plants—plants of all ages, from the rooted cutting to those four years old. The oldest plants we rely upon chiefly for flowers at this season, and the younger at spring-tide. To keep up a stock of plants we put in a batch of cuttings at any time—every month, say—one cutting to the smallest pot, in sandy loam, or loamy sand rather, for the sand predominates by being added, and they are placed under a hand-light or bell-glass. Two hand-lights are kept going for the purpose. When a batch is rooted, others follow. They are potted on gradually from two to twelve inch pots; and while in sizes less than six-inch they are stopped sufficiently to form a good bottom of from five to ten or more breaks. In this form and condition they are potted into the ten or twelve-inch pots in a pure loam, without any manure or any stimulating mixture whatever, further than a dash of sand. They get, when once the pots are full of roots, a liquid-manure watering every week from the manure tank.

Further than this, they get only that which common sense dictates, namely, staking and tying with care every growth that cannot support itself. Hazel stakes we find best for the larger plants, and Privet ones for the smaller ones; a painted stake should only be used when these are not to be got. Further, care must be used in putting long enough stakes after the second year, as the growths are sometimes over three and four feet long. We have many times seen people look critically on such long spindly-looking plants; and some gardeners, who probably have been brought up in the faith of the necessity of training everything to a formal shape, have passed them by as beneath their notice. But a dozen blooms at this season soon compensate for the want of symmetry in the plant's habit. Whoever, therefore, can't bend his ideas to the plant's wants and requirements must leave Tree Carnations alone, and seek for plants of a more uniform port.

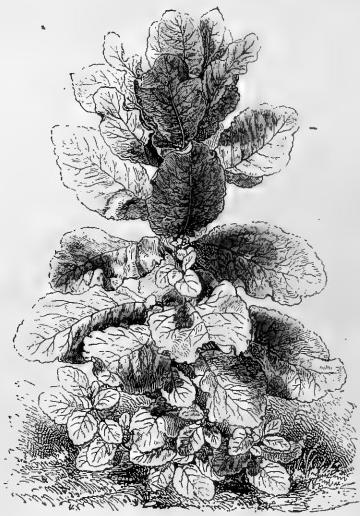

The sorts we grow are the following, and to-day more than a dozen fine blooms have been cut, and as many more could have been furnished had they been wanted:—Henshaw's Scarlet, Rembrandt, Eclipse, Hector, Comte de Douy, Beauty, M. Valiant, Eugène Dureux, Charles Baltet, Prince of Orange, The Bride, Jubilee, Belle Rose

Lady Stuart, and several seedlings of merit. Of course the summer-flowering variety, *Souvenir de la Malmaison*, finds a favourable place in the collection. Tree Carnations rank as high as the *Genardia*, *Camellia*, and *Daphne*, and are infinitely superior to *Cinerarias* and other kinds of flowers usually to be seen at this season. We grow our plants on the side stages of our heath-house, where they have plenty of head room, which they really require, for some of the plants are fully five feet high and two or three feet through. I may remark further that we cut the flowers a day or two after they are opened, if likely to be wanted in numbers, and place them in damp sand in a cool room, as we do *Gardenias* and such like flowers. In warmer, much warmer, localities, I have grown Tree Carnations out-of-doors in summer, and lifted them in autumn; but never did I find them so satisfactory as when kept always in pots—for this reason, that I failed to lift them with sufficient root to winter them well, far less to flower them to my liking.—H. K., in "Gardeners' Chronicle."

WIGANDIA MACROPHYLLA.

(*V. CARACASANA*.)

THIS noble plant, a native of the mountainous regions of New Granada, is, from the nobility of its port and the magnificence of its leaves, entitled to hold a place among the finest plants of our gardens. Under the climate of London it has made leaves which have surprised all beholders, as well by their size as by their strong and remarkable veining and texture. It will be found to succeed very well in the midland and southern counties of England, though too much care

Wigandia macrophylla (V. caracasana).—After Vilmorin.

cannot be taken to secure for it a warm sheltered position, free good soil, and perfect drainage.

It may be used with superb effect either in a mass or as a single plant. It is frequently propagated by cuttings of the roots, and grown in a moist and genial temperature through the spring months, keeping it near the light so as to preserve it in a dwarf and well-clothed condition; and, like all the other plants in this class, it should be very carefully hardened off previous to planting out at the end of May. It is, however, much better raised from cuttings of the shoots, if these are to be had. It may be also raised from seed. *W. macrophylla* has the stems covered with short stinging hairs, and bearing brownish viscid drops which adhere to the hand like oil when the stem is touched.

NOTES ON NEW HARDY PLANTS.

SOME account of two or three novelties in this way, though certainly not of the highest value, may nevertheless be without interest. The first is the so-called *Aquilegia aurea* of Roezl, collected by him in 1869 and distributed by his friend M. Ortiges, of Zurich. Of the few seedlings of this raised by myself, several bloomed during the past summer, and differed from each other only in vigour. Its habit of growth is somewhat slender, the stem reaching nearly, if not quite, two feet in height, with the characteristic binate foliage of the genus, closely resembling in detail that of the *A. caerulea*. The flowers are of medium size, with straight spurs as in *A. canadensis*, but distinguished from that species by sepals which are ultimately revolute, and by the broader limb of the petals. The colour of the flowers is not, however, golden as the name would imply, but a pale straw-colour. As a garden plant it is perhaps less showy than many other species, but will be acceptable from its distinct shade of colour as well as for its novelty.

Next I have to introduce a malvaceous plant, also one of Roezl's introductions, and sent out last season by a French firm under the name of *Malva aurantiaca-rubra*, a most objectionable compound, and one which must inevitably have been set aside, even had not the plant in question proved to be a re-introduction of an old acquaintance. It is a greyish, half-shrubby perennial, clothed with stellate hairs even to the calyxes, and grows about eighteen inches high, with somewhat weak stems and semi-trailing branches, at least those near the base. The foliage is heart-shaped, variously lobed, and incised, on longish stalks. The flowers are rather small; in axillary clusters near the top of the stems and branches, of a pale orange red, and present a rather pleasing contrast to the silvery grey of the foliage. It blooms throughout the summer and succeeds in any light soil. As already hinted, it has previously been cultivated in British gardens, having been introduced by Douglas long since, under the name of *Malva Munroana*, and has recently been transferred to the genus *Malvastrum* by Dr. Asa Gray, the specific name being retained.

The third name on my list is a Patagonian annual crucifer, *Crambe filiformis*, a name suggestive rather of coarseness and culinary herbs, than of anything at all fitted for the domains of Flora, at least that portion of them devoted to ornamental gardening.

The present species is, however, remarkable for its graceful, airy, growth, which constitutes its chief attraction, the flowers themselves being small. It commences blooming when only a few inches high, and in its earliest stages might excite but little interest; but as the season advances it throws out innumerable slender, thread-like branches, studded near their extremities with neat whitish four-petaled flowers, forming ultimately a compact little bush about a foot or more in height, and as much in diameter. It continues in blossom till the end of the summer. Though sent out by an Erfurt firm as an annual, the root appears likely to survive, so that it is probably at least a biennial.

Ipswich.

W. THOMPSON.

A New Japanese Ornamental Grass.—We now have the pleasure of bringing to notice an entirely new ornamental grass which was sent from Japan by Mr. Thomas Hogg, under the name of *Imperata japonica*. This grass has long and narrow leaves, which are variegated with green and white. The flower-stems, which are produced in great profusion, are four or five feet high, and bear at the top a cluster of flower-spikes along which the small flowers are arranged. Each of the small flowers is surrounded at its base by a ring of silky hairs as long as itself. When the grass is quite ripe, or when the clusters are cut and placed in a vase, the spike bends gracefully, and the hairs spread and give the whole head a most graceful appearance, like that of a ostrich feather. These heads will be highly prized as parlour ornaments, as they retain their beauty for an indefinite time. The name under which Mr. H. sent the plant is probably one given by some of the foreign botanists in Japan. It is, however, not an *Imperata*, as its manner of flowering is quite different from that genus. We have not at hand the materials for a proper determination, but it agrees well with the brief description given of *Eulalia japonica*—*Hortus et Home*.

We had the pleasure of seeing this grass in Mr. Hogg's garden in New York in 1870, and admired it much as a large variegated grass. The flowers, however,

are very beautiful and curious. It is probably not yet in this country.

Forget-me-Not.—Our well-known *Forget-me-not* (*Myosotis palustris*), like many more old favourites, has had of late to make room for fashionable flowers of the day; yet the endearing name, *Forget-me-not*, would have been enough of itself, one would have thought, to induce everybody to plant a small patch of this *Myosotis*, which soon spreads and becomes a bed, and when dressed once or twice during summer, by removing the old flower-stems and dead leaves, it continues to flower for a long time, and is a most useful species both in sun and shade. A good many different kinds of *Forget-me-Nots* grow wild, both in England and in southern Europe; but none are so attractive or so much admired as *M. palustris*. Nor did its beauty escape our forefathers; for we find that a collar of gold enamelled with *Forget-me-Nots* was presented by the ladies of the Court of England to Lord Scales, brother to the Queen of Edward the Fourth, as a token of their approbation and regard. Heritor and joyous, as is recorded in the English history, the Queen may add, that all who practise *Forget-me-not* culture will find it growing in marshy situations, or by the margins of streams. It will be found to be quite at home in the bog-garden; but so accommodating are its habits, that it will grow almost anywhere, and, under cultivation, its general appearance is much better than that which it has in a wild state.—A. D. ALLISON, Bishop Auckland.

YOUNG CONIFERS IN THE FLOWER-GARDEN.

Our general tendency is to plant conifers much too near the house, and in positions where they cannot attain full development. The wisest planter will ask himself, Am I placing this tree so that it may attain its fullest development? and act accordingly. Some of the most graceful conifers attain the largest dimensions, as for example, *Thuja gigantica* and the Deodar; but that they attain great proportions is no reason whatever why they should not, when young, be planted to adorn any position for which their grace and size may adapt them. The remedy is to remove them when they have gone beyond the desired size. Graceful as are young plants of the Deodar, of the *Retinosporas*, and Cypresses when well-grown, healthy young specimens of the true *Thuja gigantea* (commonly sold as *T. Lobbi*) seem to surpass them all. At least we have never seen anything in the vegetable kingdom more graceful than young specimens of this at Mount Shannon, Cork. The leading shoot especially was very striking. It seemed like a fishing-rod laden with the most exquisite fronds of ferns, each standing quite clear of its fellows, by reason of the rapid growth of the central shoot. We now have quite a number of conifers distinguished by this ravishing beauty of form when young. Few, however, surpass the Deodar in the numerous districts where it does well.

THE FORMAL
MARGIN.

No really good effect is possible in the general aspect of ornamental gardens till two simple improvements are carried out: these are the covering of bare borders, and the breaking up of the harsh and formal lines that belt nearly every shrubbery or pleasure-ground plantation with ugliness. Referring to the last only in this instance we need not remind the reader of what every person who looks into a garden must know, of the wearisome, spiritless primness that engirdles us everywhere.

The remedy is simple, yet nobody thinks of applying it. Like all really essential principles and improvements in gardening no involved arguments are necessary to explain it. But we, unfortunately, are not yet departed from the strait-laced phase of gardening. We cut in everything that stretches forth its shoots, mercifully to hide our foolishness. The first thing stupidity will ask itself on reading this note is, How are we to get the mowing done? What should we think of those who arranged a house chiefly for the convenience of the dusters? Mowing may be perfectly well done without in the least injuring the most picturesque fringe to a plantation. There is no need to go beyond the outer leaves of the outlying subjects: a little spray of long grass here and there is an

ornament, not a blemish. The effect of our gardens and public parks is materially injured by the dreary expanses of wide bare borders. In summer the effect is bad enough, but it is tenfold worse when the naked ground is sheeted with the winter's slime. On the other hand, when the trees and shrubs are allowed to throw their graceful arms over the ground, and none of these bare-dug surfaces are to be seen, the unoffended eye dwells with pleasure on the trees and shrubs. All true landscape-gardeners should save us from rigidly formal margins, and every gardener should know that to dig and trim and curve his borders into formality is to steal from them every grace. All his efforts should tend to hide instead of exposing naked earth, and to break the margins of beds of shrubs in many ways instead of carving them all to one unsightly pattern of stiff, rigid formality.

Cedrus Deodara.—(After Alphonse).

by division of the stem and rhizome; and should in all cases be planted well and singly, beginning with healthy young plants, so as to secure perfectly developed specimens. Hereafter will follow a further description and account of the culture of the most important kinds.

YUCCA ALIOFOLIA.—A fine and distinct species, with a stem when fully developed as thick as a man's arm, and rising to a height of from six feet to eighteen feet. Leaves numerous, rigidly ascending, dark-green, with a slight glaucous bloom, eighteen to twenty-one inches long, and broad at the middle, with the horny margin rolled in for two inches or three inches below the point, and finely toothed in the remaining portion. Flowers almost pure white, in a vast pyramidal panicle. This plant is hardy, but the fact is not generally known.

(To be continued.)

YUCCAS.

AMONG all the hardy plants ever introduced into this country, none surpass the various kinds of *Yucca*, or "Adam's Needle," as it is commonly called. There are several species hardy and well suited for flower-garden purposes, and, more advantageous still, distinct from each other. The effect afforded by them, when well developed, is equal to that of any hothouse plant that we can venture in the open air for the summer, while they are green and ornamental at all seasons. They may be used in any style of garden—may be grouped together on rustic mounds, or in any other way the taste of the planter may direct. If we had but this family alone, our efforts to produce agreeable and picturesque effect with hardy plants could not be fruitless. The free-flowering kinds, *filamentosa* and *fasciculata*, may be associated with any of our nobler autumn flowering plants, from the *Gladliolus* to the great *Statice latifolia*. The species that do not flower so often, like *pendula* and *gloriosa*, are simply magnificent as regards their effect when grown in the full sun and planted in good soil; and I need not say bold and handsome groups may be formed by devoting isolated beds to *Yuccas* alone. They are mostly easy to increase

THE PROPAGATOR.

THE ART OF GRAFTING.

AFFINITY BETWEEN SPECIES.—The laws of the affinities of species are almost unknown. The observations hitherto made have been undertaken in a practical rather than a purely scientific spirit, as in the fertilizing of plants. The results obtained up to the present can only be regarded as matters of fact. No theory has as yet been deduced from them, except that kinds to be united by grafting must be of the same botanic family.

For instance, the peach and the apricot are grafted on each other with difficulty, while both do well on the almond tree and the plum tree. All the cherries unite with the Mahaleb; but it will not succeed as a graft on any of the cherries. The sweet chestnut prospers on the oak; but will not do so if grafted on the horse chestnut, which belongs to another family. The medlar and the quince, which have solitary flowers, flourish on the hawthorn, whose flowers are in corymbs. The Chionanthus, so nearly allied to the lilac by its panicled flowers and simple leaves, only succeeds well on the common ash and on the flowering ash, which have compound leaves. On the other hand, the Sorbus, with pinnate leaves, is more vigorous when grafted on the thorn, whose leaves are more entire than when grown on its own roots.

The grafting of evergreen trees on deciduous kinds presents more than one singularity.

The Photinia, allied to the beam tree, the Eriobotrya, allied to the medlar, are grafted on the medlar, and not on the hawthorn. On the last, as a stock, the Cotoneaster and the Pyracantha do well. The Mahonia flourishes on the Berberis, and the common laurel succeeds on the bird cherry and even on the wild cherry, from which it differs so much in appearance.

The grafting of deciduous plants on those that are evergreen has, in almost every case, been attempted in vain. Those who are fond of oddities can, with the assistance of grafting, have on the same thorn stock at the same time fruiting branches of the pear, the medlar, the beam tree, the Service-tree, the mountain-ash, the European and Japanese quince, and also see there the flowers of the double and red thorns, the Cotoneaster, and the Pyracantha.

They may gather from the same plum-stock plums, apricots, peaches, nectarines, almonds, the corymbs of the Canadian cherry, and flower garlands of the Chinese and Japanese plum. But these whimsicalities are unworthy the attention of cutivators.

Whoever wishes to study grafting in the works of celebrated ancient authors or horticulturists will find a string of absurdities, some of which we shall mention. Virgil speaks of a plum-tree which bore apples after having been grafted, and recommends the grafting of the pear on the ash. Martial advises the grafting of the cherry on the poplar. Columella, whose works are equally trustworthy, would have the olive grown on the fig. Palladius speaks of the walnut being grafted on the Arbutus, the pear on the almond, and the citron of his native island of Sardinia on the mulberry-tree. Pliny considers thunder injurious to trees grafted on the white thorn.

Madame de Genlis, it is said, grafted the rose on the holly or the black currant, in order to obtain green or black roses; and the Abbé Rozier recognised the possibility of it. Others united, in their imagination, the apple to the briar, hoping to gather therefrom Calvilles; the orange to the holly, in order to acclimatize the former in open woods; the vine to the walnut-tree, so as to have grapes full of oil. They are merely so many hallucinations, like the story of a cornel grafted on a peach-tree in a garden at Troyes, published by M. de Caylus in his "History of the Conjunction of Plants." The ancients are not the only persons guilty of falsification in the matter of grafting. There have been many instances of it in our own time, and we shall long continue to hear of black roses being produced from a black currant stock, &c.

MUTUAL VIGOUR OF THE PARTS.—It will always be better to unite by grafting only such subjects as have between them some analogy in point of vigour, time of commencing to vegetate, and hardiness. If any difference should exist, it would be preferable that the graft should be of later vegetation

than the stock, and also more vigorous and hardy. Tender varieties suit well with a stock of moderate vigour; but on a weakly stock they produce a worthless tree. When grafted on too vigorous a stock, it is difficult for them to absorb all the sap furnished by the roots; an evenness of growth cannot be established between the stock and the graft. Then follow weakness and disease—disagreeable results. The reverse of this, to have the graft more vigorous than the stock, is more admissible. The pear-tree on the quince, the apple on the paradise, the cherry on the Mahaleb, give us proofs of this. The tree will be less vigorous than if perfect harmony existed between the two parts, and its growth being thus tempered, it tends more to the production of fruit. Very great differences in the matter of vigour may be lessened by means of double grafting, in which we first graft on the stock a variety of intermediate vigour, and on this, later on, we graft the variety which we desire to propagate. The stock should always be strong enough to receive the graft. If it is weakly, although the graft will unite with it, the future tree will always be tender. Stocks that have been planted a year at least should be employed. The number of the grafts on each stock should be in proportion to its vigour, so as to obtain the favourable results which will follow from the exact adjustment of the powers of vegetation. Sometimes grafting is successfully performed, during the repose of the sap, on stocks taken up out of the soil, which are replanted immediately after grafting. The graft, on its part, should come from a pure source. The tree which furnishes it should be healthy, if it is desired to transmit health and hardiness. In the raising of plants, it is easier to prevent than to cure disease. The degeneration—more apparent than real—of species and varieties is especially due to the selection of bad subjects for propagation. The parent plant or tree which furnishes the scions should always be of a strong, healthy constitution.

INTIMATE UNION OF THE TWO PARTS.—In every kind of grafting it is indispensable that the two parts grafted should be in close communication, not by means of the epidermis or the pith, but through the generating layer—that is, the new and living layers of inner bark or albumen, in the tissue of which the cambium flows. A perfect joining is not effected except on this condition. The multiplicity of points of contact is favourable to a more complete union, which will also be assisted by a similarity of texture between the scion and the stock, especially as regards the herbaceous or woody nature of their tissues. Lastly, the speedy cohesion of the parts depend on the skill of the operator, who should know how to avoid wounds, or to cicatrize them, and to preserve them from the action of the atmosphere.—*C. Baltet's "L'Art de Greffer."*

(To be continued.)

THE FRUIT GARDEN.

FOUR NEW PEARS.

The domains of Pomona are at present so richly furnished that it may be asked, "What new pears can be announced as surpassing in merit those already known?" It would appear, in fact, that after the Epargne, Beurré Giffard, André Desportes, William, Beurré d'Ananlis, Monsallard, Boutee, Madame Treyre, Sénateur Vaïssa, Souvenir du Congrès, and Comte Lelieur, no other good summer pears could be discovered. We are inclined to think, and with good reason, that of recent varieties of autumn pears none can surpass in quality the Beurré Baltet, Beurré Benoit, Seigneur, Beurré Hardy, Beurré Superfin, Fondante des Bois, Hélène Grégoire, Louise boune d'Abranches, Thompson's, de Tongres, Beurré de Nagnie, Marie Louise, Doyenné du Comice, Duchesse d'Angoulême, Napoleon, Beurré Dumont, Doyenné Boisnard, Van Mons, Sucrée de Montluçon, Ne plus Meuris, Fondante du Panisel, and Beurré Bachelier, all of which are pears of unexceptionable quality, and, finally, that the Beurré Diel, Triomphe de Jodoigne, Figue d'Alençon, Leon Grégoire, Jules d'Airoles, Passe Colmar, Beurré d'Hardenpont, Orpheline d'Enghien, Nouvelle Fulvie, Marie Benoît, Duchesse de Bordeaux, Passe Crassane, Olivier de Serres, Doyenné d'Hiver, Doyenné d'Alençon, and Bergamotte Esperen will long remain unrivalled as first-class winter pears.

In these prefatory remarks, let us not forget our fine old acquaintances the Beurré Gris, Doyenné d'Antoine, Crassane, St. Germain, and winter Bon Chrétien (which are not to be surpassed in the flavour of their fruit, but which are, unfortunately, not always of robust growth, unless when grown on a wall), nor the delicious little pears, Doyenné de Juillet, Citron des Carmes, Rousselet de Reims, Avocat Allard, Monsieur Sibour, Colmar Nelis, Zéphirin Grégoire, Castelline, Beurré Millet, and Joséphine de Malines, which for family use are more highly esteemed than the enormously large Van Marum and Belle Angevine.

Do not, however, be mistaken. The pear-tree is so variable in its fruit (different kinds ripening at different periods throughout the four seasons), that there is always room in the list for any new acquisition which recommends itself by the vigour, habit, or productiveness of the tree, or by the size, shape, and colour of the fruit, and, above all, by the rich qualities of the flesh, which may be sugary, or vinous, sweet or acidulous, juicy or perfumed, whatever may be the season at which it ripens.

These considerations have induced us to give the first place in the list of pears to Clapp's Favourite, the Poire de l'Assomption, the Fondante Thirriot, and the Beurré Baltet père:

CLAPP'S FAVOURITE.—Raised in America, it has been highly extolled by Downing, and is in every respect deserving of the praise which he has bestowed upon it. The tree is magnificent in the vigour of its growth, and in appearance, and in point of productiveness leaves nothing to be desired. The fruit is of the largest size, very handsome in shape and colour. Sometimes it is so highly tinted with carmine, that one would imagine it to be a William, an Espagne, or a Louise bonne d'Avranches; at other times it takes the appearance of the Poire d'Amour, or the Bon Chrétien de Vernois, and remains yellow, with a fine green under-tint. The flesh is fine, snow-white, melting, and of a delicate flavour. It ripens about the middle of August. Clapp's Favourite will be highly prized at the most sumptuous desserts, and will be a valuable subject for the speculative cultivator. It does well either on its own roots or grafted on the quince; accommodates itself to the pyramid or palmette form, and succeeds equally well in the open ground or on a wall. If the wall is fully exposed to the sun, the fruit should not be allowed to ripen on the tree. In 1871 Clapp's Favourite and the Souvenir de Leopold First produced the two largest pears that we gathered.

POIRE DE L'ASSOMPTION.—If we consider the enormous prices which are sometimes asked for new varieties, this pear is well worth the 2,000 francs its raiser, M. Ruillé, of Beauchamps, in the Lower Loire, demands for the sole right to its possession. Imagine a tree like a thick-stemmed Colmar d'Arenberg, with short branches laden with fruits which resemble sometimes a large short Colmar or a broad Duchesse, sometimes a pyriform William with an indented skin, of a delicate yellow streaked with red and sometimes tinted with carnation. The flesh is delicate, melting, exceedingly juicy, sugary, perfumed, and refreshing at all its periods of ripening, which extend from the middle of August to the end of September. The tree may be grown as a pyramid, palmette, small candelabrum, and cordon, in the open ground or on a wall, in the sun or in the shade. It is particularly well adapted for the columnar form, which is its natural habit, and which, as occupying but a small area, is calculated to secure it a place in every fruit-garden. It does well either on its own roots or grafted on the quince.

FONDANTE THIRRIOT.—This, named after its present possessor, who at first intended to call it Triomphe des Ardennes, grows on a very vigorous, branching, tall, and productive tree. The fruit is rather large, and grows on long stalks in clusters. In shape it is cylindrical-obtuse, sometimes pyramidal or truncato; the colour being of a fine green, passing into light yellow, spotted and shaded with rose-colour. The flesh is white, delicate, often melting, often half brittle, always sugary. It is best in quality in the earlier stages of its ripening, which takes place in September and October. The tree, which is vigorous both on its own roots and when grafted on the quince, is well adapted for orchards or fruit gardens, as a tall standard, pyramid, vase, candelabrum, in the open ground or on a wall.

BEURRE BALLET PERE.—This, raised from seed by the writer's father, is a fruit of the largest size and first quality, produced in abundance on a tree of low and handsome habit. The form of the fruit varies from the pyramidal top-shape to the thickly-rounded; the colour passes from a lively green to a sulphur yellow, with a slight tinge of vermilion and a few reddish spots. The flesh is very delicate and melting, juicy and with a fine and agreeable flavour. The earliest begin to ripen in the commencement of October, but the usual or regular

period of ripening is during the whole month of November. At the present time (the first fortnight in December) we have some fine specimens still hanging on the trees. The tree is robust, of low habit and handsome growth, either on its own roots or grafted on the quince. It adapts itself to all forms of training, whether as a pyramid, column, palmette, candelabrum, goblet, or standard, in the open ground, or on walls with different aspects. The superior property which the fruit possesses of hanging long on the tree indicates that the Beurré Baltet père is well adapted for planting in orchards exposed to winds from all quarters; but it should be gathered before the first white frost come on. During four years in which we have studied this pear in our experiment-grounds and pomological schools, its good qualities have never once disappointed us.

Troyes, France.

CHARLES BALLET.

A NEW WAY TO "MAKE" FRUIT-TREES.—Mr. Sullivan Hutchinson, of Bristol, New Hampton, received letters patent last May for a new and novel invention for making productive fruit-trees in a single year from fruit-bearing limbs. Limbs that can be spared from trees that bear desirable fruit are transformed into independent trees, which will bear right along, just as though they had not been severed from the parent stock; and in a short time become fine, thrifty trees, retaining the habits of the parents from which they were taken. This is what Mr. Hutchinson claims his invention will do, but from the imperfect description we have had of the process, it is impossible to give a very clear idea of how the thing is done. Into the limb, however, which is intended for the future tree, small roots are grafted just above where the limb is severed. Below these roots the branch is girdled. About and below the roots is placed a box filled with earth. This operation is performed in the spring. During the summer the roots grow, and life is thus established between them and the limb above. In autumn the limb is severed at the place where it was girdled, and set in the ground in the same way any young tree would be. The next year, according to Mr. Hutchinson's statement, this new tree will bear fruit just as though it had not been cut from its parent. To what extent this operation may be carried, and how successful it may prove, remains to be seen. Experiments to a considerable extent have been made in Bristol and New Hampton, and we hear that farmers in various parts of the State are buying town and farm rights with the intention of testing the practicability of this new system of producing early-bearing fruit-trees. If successful, a complete revolution in our manner of obtaining apple trees will be the result. Instead of buying trees from the nursery, which require years to come into bearing condition, the limbs from our old trees will be converted into new ones that will give us fruit at once.—*Gardener's Monthly*.

STRIPED AND VARIEGATED FRUITS.—Although fruits are mainly valued for their edible properties, says Mr. Barron, in the *Florist and Pomologist*, yet if equal excellence can be obtained under a more beautiful exterior, the combination of the two qualities is certainly to be preferred. Some object to the colouring of striped fruits, and fancy that they have too much of a painted look about them to be good to eat; but many of these fruits are as well flavoured as the ordinary kinds. The following is a list of all the examples of striped fruits which I can at present call to memory:—

FIG.—Col de Signora Blanche Panaché: green striped with bands of bright yellow.

PARSNIPS.—Beurré d'Anjou Panaché: beautifully marked with broad bands of bright red and yellow, very striking and pretty constant; desirable. Duchesse d'Angoulême Panaché, or Duchesse Panaché: the quiet green of this fruit is prettily set off with broad stripes of deep yellow. Louise Bonne d'Avranches Panaché: this is Louise Bonne of Jersey, very prettily striped with broad bands of rose red and yellow; very handsome. Virguleuse: fruit pale yellow, striped with rose red. Culotte de Suisse: fruit light green, striped with yellow. Winter Crassane: fruit pale green, striped with yellow.

APRICOTS.—Reinetto Rayé: this is an exceedingly pretty little fruit, very evenly and regularly marked with broad bands of red and yellow. Red-striped Apricot: fruits striped with yellow slightly rose; leaves resembling those of the auburn. Ivory Morning: very beautifully striped with rose red. Yorkshire Greening: this is at times prettily marked, but not constantly so. Devonshire Red Stripe: slightly striped. There are besides many apples showing streaks of colour, but they are not sufficiently distinct to be here noticed.

GRAPE.—Alleppo Chasselas Panaché: this is a most singular variety, some berries being prettily striped with black and red, or white, some half black, others half white or red, others again wholly black, red, or white; leaves striped with green, red, and yellow.

APRICOT.—Abricotier Panaché (the striped apricot): fruits medium-sized, pale orange, streaked on the exposed sides with bands of reddish orange and pale yellow; leaves prettily blotched with yellow.

CARROT.—Striped-fruited: the fruits of this variety are yellow, distinctly striped with red; it is, however, a very shy bearer. Commune à Feuilles Panachées has also the fruits slightly striped, and the leaves variegated.

MELONS.—Queen Anne's Pocket: the fruits of this are quite of an ornamental character, small, round, and prettily striped with broad bands shading from dark orange to pale yellow. All the other varieties of Cucumis Meloidaim, to which this variety belongs, are of a pale green colour. There are, besides, numerous varieties of melons, which are wonderfully beautiful in their striping; but these, though technically coming under the designation of fruits, since they are not practically used as such, are here passed over.

How to induce Seedlings, Fruit-trees to Bear Early.—At a meeting of the Royal Horticultural Society, the following communication was made by Rev. W. Kingsley was read:—"Everyone knows how very long is the time between sowing the seed of a fruit-tree and getting fruit from it, so that few men of fifty years of life have the courage to propagate seedlings. I believe the time may be shortened most materially, and that a very few words will explain the correct way of growing seedling fruit-trees. I have been led to the idea by the difficulty I have had in getting some grafted trees into bearing, and by observing that the fruit of the seedlings of grafted trees bears earlier than that of the ones grafted in suckers from old ungrafted trees. In almost all these cases, whether apple, pear, plum, peach, or orange, the wood was thorny; and when I cut back, and used the cutting for scions, all had the same thorny and fruitless character. However, in experimenting upon a set of seedling peaches, some were allowed to grow wild, some steadily pinched in, some cut in closely and pinched, and some trained as single rods; all these last fruited as soon as the short ones did, and the thorniness was gone. It therefore occurs to me that it was only necessary to get behind and part the growth as quickly as possible. This is done by encouraging the growth of the young seedling to a single upright shoot, and then using the point of that shoot as a scion on a strong stock; then the shoot from this scion is to be again trained at full length, and its point again used as a scion. In this way a shoot may be having buds twenty feet or more from the root in a couple of years. I can speak from experience of the ease of grafting the fruit of peaches and oranges, and some plums; pears and apples I have not yet tried. In this way there will be no difficulty with thorny pear-trees. The trees that I could not get to fruit had been grafted with scions taken off too near the root, the sorts being new ones. By selecting the scion near the root, or far from it, a grafted tree would be produced that would bear only after a long interval or quickly, according to the gardener's will. At any rate, what has been said shows the importance of choosing the points of the leading shoots as scions for forming dwarf trees."

GARDEN DESIGN.

LANDSCAPE TREATMENT OF FARMS.

In reference to the possible connection of landscape art with lands submitted every year to agricultural and economic uses, I propose to examine the matter in detail. If all farm-lands showed only the method of Alderman Mechi, and his system of pumping liquid manure by steam into the middle of any field—to be distributed thence by hose and sprinklers—should prevail, we should have, of course, only flat surfaces and rectangular fields to deal with. But it is safe to say that it will not prevail upon most of our farms for many years to come; yet it is none the less true that farm-lands are chiefly valued for the crops they will carry, and for the annual return they will make. Are lands under such rule of management susceptible of an aesthetic governance as well? Will treatment with a view to profit discard, of necessity, all considerations of tasteful arrangement? I think not, and for reasons among which I may adduce the following: Judicious location of a farm-steading, with a view to profit simply, will be always near the centre of the lands farmed: this is agreeable, moreover, to every landscape-ruling in the matter. The ricks, the chimney, the barn-roofs, the doo-cots, the door-yard with its skirting array of shrubbery and shade trees—if only order and neatness belong to them, as good economy would dictate—form a charming nucleus for any stretch of fields. If there be a stream whose power for mechanical purposes can be made available, economy dictates a location of the farm buildings near to its banks: taste does the same. If there be a hill whose sheltering slope will offer a warm lee from the north-westers, a due regard for the comfort of labourers and of beasts, to say nothing of early garden crops, will dictate the occupancy of such sheltered position by the group of farm buildings: taste will do the same. If such slope has its rocky fastness, incapable of tillage, and of little value for pasture, economy will suggest that it be allowed to develop its own wanton wild growth of forest: a just landscape taste will suggest the same. If there be a broad stretch of meadow or of marsh land, subject to occasional overflow, or by the necessity of its position not capable of thorough drainage, good farming will demand that it be kept in grass: good landscape gardening will do the same.

Again, rolling hillsides, which, by reason of their declivity or impracticable nature, are not readily subject to any course of tillage, will be kept in pasture; and will have their little modicum of shade. The good farmer will be desirous of establishing this shade around the brooklet or the spring which waters his herd, or as a sheltering belt to the northward and westward of his lands: the landscapist cannot surely object to this. The same shelter along the wayside is agreeable to all aesthetic laws, and does not surely militate against any of the economies of farming. Indeed, I may remark here, as I have already done in the progress of these pages, that the value of a sheltering belt of trees is not sufficiently appreciated as yet by practical farmers; but those who are not insensible to the quick spring growth under the lee of a garden-fence, will one day learn that an evergreen belt along the northern line of their farms will show as decisive a gain in their fields or their orcharding.

Again, in the disposition of roadways, there is no rule in landscape gardening which is not applicable to a farm. Declivities are to be overcome by the easiest practicable grades, and the curves which

will insure this in most landscapes are those which are justified at a glance by the economic eye, as well as by the eye of taste. A straight walk up and down a hill, is a monstrosity in park scenery; and it is a monstrosity that cannot be found in pasture-lands, where cattle beat their own paths. Even sheep, who are good climbers in search of food, whenever they wend their way to the fold, take the declivities by zig-zag, and give us a lesson in landscape art. An ox-team, in worming its way through woodland and down successive slopes, will describe curves which would not vary greatly from the engineering laws of adjustment.—*Rural Studies.*

OAK LODGE, ADDISON ROAD, KENSINGTON.

THAT "in small proportions we just beauties see," is well illustrated in garden design. It is most rare to find a large place "well laid out." Places of this description of any size are unfortunately too rare, but for the truest examples of taste in garden design we must go to comparatively small places. The best example we know of a well-arranged garden in London is the one of which we now furnish a view of part of the grounds. As we have not at present a plan of it, we must confine ourselves to saying a few words on the portion shown in our plate. Perhaps the first thing asked by some of those who have not seen the charming garden, of which our illustration gives but a feeble notion, will be, Why is a rock-garden in such a position? Because a formal and ugly duck-pond and island were there before the garden was designed, and the lease stipulated that there, they should remain. Permission was, however, granted to modify the scene a little, provided the water, &c., were not "done away with." Here, then, was a problem: a small formal pond and an ugly formal bank just in the place where a clear-seeing landscape-gardener would desire a little repose and a spread of velvety grass. But it was solved, and ably solved. The ugly bank became a varied mass of picturesque rock, seamed with graceful ferns and trailing shrubs; the water fell into what seemed a natural hollow in the earth, and around it sprang up tufts of Iris and Yucca. Rich masses of specimen Rhododendrons crest the rocks. The rocks, in fact, form a sort of retaining-wall for the masses of earth to accommodate these plants. Some old pear-trees and a pair of grand old Wych elms were carefully preserved, and grandly add to the effect of the scene. Mr. Alfred Dawson, who sketched and etched the view for us, does not usually betray any animosity to a well-garlanded rock-garden, but in this case he has, while giving us the rocks faithfully enough, been somewhat cruel to the graceful drapery of vegetation with which they are clothed by ignoring its existence to a considerable extent. It is a mass of artificial rock cleverly and artistically constructed, but, like all masses of the same species of rock, it is not suitable for alpine and rock plants, &c. The opposite side of the rock is very much more attractively varied with gently swelling banks and tastefully grouped masses of shrubs; and there are various other very praiseworthy features about the grounds. Although the place is only a few acres in extent, and in a comparatively closely-built neighbourhood, it seems as free and broad, to one standing on the lawn, as if it were fifty. The boundary-line is so skilfully managed, and the surroundings so carefully concealed by a graceful veil of trees and shrubs, that the feeling of repose is perfect. Oak Lodge is the residence of Mr. McHenry, for whom it was designed by Mr. Marnock.

The Axe a Magician.—While selecting the best site for a mansion, one of the chief objects to be considered is the view to be obtained from the principal windows of the house when completed; such as distant mountains or hills, church spires, towers, castellated buildings; frequently rivers, lakes, and even the open sea. After the house has got a certain length on, the artistic laying out of the grounds is the next point of consideration, and this is generally done by forming kitchen and flower gardens, evergreen shrubberies, and, for the better protection of the house and grounds, finishing off with clumps or belts of trees of various breadths, planted round the outside boundary fence. When the gardens are at first laid out the trees are generally small, and the views so extensive that the possibility of their being ultimately shut out is never taken into consideration. As time rolls on, many of these residences become buried up amongst a dense forest of trees, and few of the original panoramic views are visible, unless one ascends to some eminence or gets outside of the

VIEW IN THE GARDENS, OAK LODGE, ADDISON ROAD, KENSINGTON.

wall. Such shut-up places coming into the market are frequently undisposed of for a length of time, owing to their close and damp nature, the unsuccessful owner never for a moment thinking that such closeness can be easily cured. Some parties, more knowing than others, often secure such secluded places, and immediately commence a reformation; the charm worked by the woodman's axe, with the aid of the artist or landscape-gardener, is often marvellous, and at a comparatively trifling expense, in certain cases the nature of the thinnings paying for the improvement effected. After the cutting for utility, as well as for landscape effect, has been accomplished, the debris all cleared away, and the place again put into proper condition, its market value will be found to be greatly increased. In some localities the stem-pruning of a few of the large specimen trees often produces a peculiar but pleasing effect while looking at views between the stems and beneath the spreading branches. In other cases, the heading down of some of the intervening trees and the trimming up the branches of neighbouring ones also tend to bring in views which have long been shut out. In some instances the removal of trees altogether, and the stem-pruning and branching of others, produce views truly grand, and without in the least degree injuring the health of the trees operated on. A mansion-house known to me, situated on a somewhat rising ground about a half a mile from the sea, but which was almost excluded from it by large trees and a thicket of evergreen and deciduous shrubs, by the judicious removal of some of the under branches of the large and wide-spreading trees, the clearing or thinning out of a few of the evergreen and deciduous shrubs, and the partial heading down of others, beautiful views of Inchkeith and the Firth of Forth have been obtained from the principal windows of the mansion. At another large mansion, the removal of a gigantic oak tree in front of the drawing-room windows has opened up, on one side, a rich expanse of country, with hills and wooded glens, which before was scarcely visible except through a network of branches, and that during the leafless months of the year. On another property, the breaking through some extensive belts of spruce fir has been the means of varying and improving the foreground landscape, besides bringing into view a range of hills and wooded banks, with here and there the entire outline of a fine old Scotch fir or beech tree, which, if well shaped, forms a beautiful object in the landscape. Although the remarks here given refer to vistas and views as applicable to mansion and villa residences, such effects to be produced by openings are equally applicable to the wooded banks of rivers, extensive woods, and wooded glens quite remote from dwellings. The eye, when once practised to such landscape effects, will find on many large properties numerous spots eminently calculated for such openings.—*Jas. M'Nab, in "Farmer."*

THE GARDEN IN THE HOUSE.

FORM OF DINNER-TABLE PLANTS.

It has been the fashion for three or four years past to bring into descriptions of many of the new plants that have been introduced during that time the assertion that they are suitable (or invaluable) for dinner-table decoration. This may mean that the leaves or the flowers of the plant are capable of arrangement in a vase so as to look well upon a dining table; but that is not the meaning which these words convey to the majority of those who read them. When a plant is mentioned as desirable or useful for any particular purpose, readers in general, and gardeners especially, conceive that the writer refers to the whole plant, and not to any individual part or parts of it; and as a result of such recommendations we often see plants put upon dinner-tables that are utterly unfit for such a position. I have been led to notice this at the present time in consequence of some remarks which have recently appeared with respect to *Amarantus salicifolius*, of which beautiful plant I was favoured with a very early view. I may therefore count myself amongst the first and oldest of its admirers since its introduction into England, and I regret to see it proposed to be used in an unsuitable manner. It is noteworthy and characteristic of their good taste, that the firm who introduced it do not advertise the plant for dinner-table purposes.

The following are extracts from the remarks to which I refer:—“*Amarantus salicifolius* promises to be the finest-foliated plant for dinner-table decoration for 1872. . . . It is a free-growing plant of admirable habit, forming a dense weeping pyramid of about a yard high, and nearly as much through. . . . It will obviously give a new character to dinner-table decoration.” Assuredly it will be a novel feature, as well as a most unmitigated nuisance, if plants three feet

high and three feet in diameter are allowed to be placed on a dining-table. I do not say that the plant cannot be made available for dinner-tables. To us in the metropolis it has the great drawback that it does not begin to assume the beautiful colours in its leaves until the London season is over, while those who, in the country, can use it as an in-door plant will find it more suitable for breakfast and luncheon decoration than for dinners, as its colours do not show to advantage by artificial light. It is quite possible that, for daylight use, good dwarf plants might be obtained by late sowing, and also that suitable plants might be “manufactured” by removing all the lower branches from a plant of the usual size, thus converting it into a standard, with a stem about two feet high; but I scarcely like to suggest such interferences with the natural appearance of so elegant a plant: and the more so, since there are so many plants well suited to the purpose, without requiring to be tortured into forms foreign to their normal style of growth.

It cannot be too often repeated, for the information of those who write or talk about the suitability of plants for dinner-table decoration, that plants for that purpose must come under one of the following categories, or they are inadmissible:—They must either be below fifteen inches in height, so that those seated at the table may see over them; or they must be standards, and have no branches or leaves within twenty inches of the cloth, so that diners may see under them. Any object that interferes with the view across a dining-table between fifteen and twenty inches above the cloth, is an inconvenience to those at the table, and should never be allowed.

W. T.

THE CULTURE OF PLANTS IN ROOMS.

(Continued from p. 90.)

In order to grow perfectly good and fine specimens in a room, the best thing to do is to select small plants in small pots, so that the subjects may become gradually acclimated to the atmosphere, and capable of supporting it permanently. In this way a partial deterioration of the foliage may occur, which, however, will not be followed later on by any serious diminution of the appearance or beauty of the plants, and, moreover, in small pots the roots suffer less when any injury occurs to the leaves. A normal condition of health can, in the last case, be sooner re-established by placing the little plants in the most favourable part of the window until they have grown sufficiently strong to be moved elsewhere. It is only after the establishment of the new growth in the atmosphere of the room, when the plants have been thus accustomed to it, that they are to be shifted into larger pots, for which directions will be given further on.

Some instances from the author's experience will show that when a man does not allow himself to become discouraged, but rather gives double attention to such plants as appear to droop at first, he is likely to be well rewarded for his care.

A feeble specimen of *Dracena concinna* was brought from the plant-house into the dwelling-house. All its leaves, except a few, dried up and withered, but they began to grow again, and stronger and stronger from year to year, so that now, after the lapse of six years, the plant retains the greater part of the leaves produced in the room, and has grown to be such a strong and handsome specimen as one is seldom fortunate enough to raise in a plant-house. In the first year only small and narrow leaves were produced, but after that time they grew larger, broader, and more luxuriant from year to year, and never showed any of the ugly spots which are so often seen on the leaves of these plants in plant-houses. Now the plant has a crown of forty healthy leaves, which are more than two inches broad, and more than two feet long. About the same time with the *Dracena concinna*, a specimen of *Dracena Jacquinii*, Kunth. (*D. ferrea*, “*Hort.*”) was removed into the dwelling-house. In spite of every attention this plant always looked miserable, finally lost all its leaves, and, in consequence of the partial decay of its roots, was shifted into a smaller pot, and placed in the window. Before it had stood there quite a year, it had put forth a new and strong growth; was then shifted into a large pot, and soon made a fine specimen, with twenty leaves a foot and a half long and three and a half inches across, of a dark red colour, which it preserved pure and without spots. A specimen of *Dracena marginata* (*Lam.*), about a foot high, was also brought into the room. In the course of three years it had grown five and a half feet high, and preserved all its leaves (except those which were produced in the plant-house), so that, from one foot above the ground to the top of the plant, it was thickly covered with foliage.

The last instance we shall mention is that of a specimen of *Cordyline*

cannabifolia (R. Br.) - Knowing from experience that the best way to grow a good specimen of this plant in a room is to remove it thither in a young state, we brought in in a two-inch pot a very young plant, the roots of which reached the sides of the pot. Soon after its removal all the leaves died off one after another. However, the plant was placed in a sunny part of the window, and in July (it had been brought into the room in April) it produced the first new leaves, and at the same time roots which filled the pot. It was then shifted into a larger pot, and by autumn had produced eight new leaves, of which the largest were one and a quarter foot long, including the leaf stalk, and one and a half inch across. In the course of the following year it developed twenty-four new leaves, three feet long and three and a half inches across, so that it soon became a particularly handsome specimen, and remained for a long time thickly covered with leaves from the ground up.

These few instances may suffice to show that evergreens which are intended to be kept permanently in rooms, must first be gradually inured to the atmosphere, and must first have made a new growth, in it, before they can be looked upon as fully acclimated. But the amateur who, when his plants on their first introduction into the dwelling become ill-looking and sickly in consequence of the change, removes them, and supplies their places by others, will very seldom succeed in growing good or durable specimens.

The following precautions should be observed, in order to prevent, as much as possible, any injury to large plants when removed from the plant-house into the dwelling house:-

1. Do not select any specimens in growing condition, but choose those which have made their full growth, or such as are only commencing to push. The younger and more recently formed the leaves are, so much the more susceptible are they of being spoiled by being introduced into the atmosphere of a room.
2. Choose, if possible, the summer for introducing the specimens from the plant-house into the dwelling-house, as, the air being admitted into both these places at that season, the difference in the moisture of their respective atmospheres is not so considerable.
3. In removing plants into a warm room for the winter, do not select any which are growing in a low, moist plant-house, but such as have been already hardened in the drier air of a high and dryish house. Care should be taken in this respect, not only with plants which are intended for permanent culture in the dwelling-house, but also with those which are only placed there for temporary decoration.
4. Plants when first introduced into a room should be placed as near as possible, to the window, with some shading from the direct rays of the sun in spring and summer. This protection will only be necessary for a short time after the introduction of the plants.
5. Plants removed from a moist plant-house should be sprinkled with water every morning and evening for the first week, which will prevent the injury which would result from the excessive evaporation from the leaves.

In foregoing remarks we have discussed the question of the introduction of plants into the rooms of dwelling-houses, but we must here impress upon all amateurs the caution that they will imperil, and probably destroy, all the results of growing plants in rooms, if they attempt to remove periodically into the open air, or into a plant-house, any evergreen subjects that have once been used to the atmosphere of a room. The following is an instance in the experience of the writer:- From some Cordylines which had been grown for years in a room, a selection was made of those kinds which are well known to be capable of enduring the open air in summer. These were placed in a glass-roofed balcony with open sides. Here, very soon indeed, *Cordyline rubra*, *C. violascens*, *C. australis*, *C. spectabilis*, and *C. stricta* put forth a new and a stronger growth than they had made in the room. A specimen of *C. australis*, which had been already cultivated in the room for two years, and was covered with a mass of handsome overhanging leaves, especially distinguished itself by the development of leaves much larger, broader, and of a deeper green, just such as this species only produces when placed in the open air in summer. In the midst of this growth, these experiment plants were taken back into the room in autumn; but the results of moving them were very unfavourable to all the plants. In the course of the following winter, *C. australis* lost all its old leaves and a portion of the new ones as well, and continued in a very sickly condition all through the winter, so that this fine specimen, which had kept its leaves for three years, was quite ruined by the experiment. *C. stricta*, which is one of the most durable plants for room-culture, and which, to be sure, on this account had, when brought back to the room, been placed in a rather dark part at a distance from the windows, gradually lost all its leaves and soon died.

That these injuries, which all the other plants which were thus

experimented on likewise suffered in the loss of all their old leaves and a portion of the new ones, could only be attributed to their having been shifted from the room to the open air, was manifest enough from the fact that all the other specimens, which passed the summer in the room, continued to grow away uninjured as in former years. The falling off of the old leaves was in this case entirely the result of the reaction of a summer's growth made under different conditions and influences, and which cost the plants the loss of the advantages of several years' acclimation in the room. The partial loss of the leaves of the new growth resulted from this circumstance, that that growth was not quite completed when the plants were brought back into the room, where the higher temperature stimulated them to a further growth in the course of the winter. This part of the injury might have been prevented by removing the plants back to the room somewhat earlier in the season.

It is to be understood that all the preceding remarks on the acclimation of plants in rooms are applicable only to the more important evergreen ornamental plants, whether intended for the temporary or permanent decoration of apartments.

For the management of plants flowering in winter and spring, the rules just given will be useful; but for summer-flowering plants, such as fuchsias, pelargoniums, &c., the room is merely a winter shelter. As we have devoted separate chapters to the various aspects of room culture, we shall give the necessary directions in the proper place.

What has been said respecting evergreen ornamental plants will apply equally to all flowering plants with evergreen foliage, which are wintered in ordinary dwelling-rooms with a temperature of from 10° to 15° Réaumur. Such are camellias, Indian azaleas, &c., of which many amateurs purchase very handsome specimens at high prices. The buds with which these specimens are thickly covered excite lively expectations of future flowers. But it happens otherwise. In spite of the greatest care one bud after another drops off without opening, and with them all hope of flowers fall equally to the ground.

Even when camellias are grown in a plant-house, a change of position usually proves highly detrimental to the development of bloom. In a much greater degree is this the case when a camellia, raised in a plant-house and covered with buds, is transferred to the dry air of a dwelling-room. But the amateur who wishes to succeed with these plants should not allow himself to be discouraged by the unfavourable results which always follow for the first year after their removal, but should rather continue his care of them. His perseverance will be rewarded by the success of growing camellias in a dwelling-room to as fine specimens and as well furnished with flowers as it is possible to do in any plant-house. These plants, like the evergreens, should make a new growth in the apartment to which they are removed, and, like them, should not be afterwards shifted to the open air. The special treatment of these handsome plants will be fully given in its proper place.—From the German of Dr. Regel.

(To be continued.)

THE VARIEGATED PINE AS AN IN-DOOR ORNAMENT.

NOTHING could be more appropriate or decorative as an in-door ornament than a well-grown entire plant of the variegated pine-apple, especially one grown expressly for the purpose, the fine development of the foliage having been carefully attended to. A fine plant so treated, and placed within a handsome majolica vase, large enough to conceal the pot in which the plant is grown, could not fail to be strikingly effective either in halls, corridors, or grand staircases—aye, and even for vases placed upon terraces in the open air during the summer season. The variegated variety differs from the normal form of pine-apple in its foliage being broadly laced with orange-yellow, suffused when younger with reddish-crimson colours, which contrast beautifully with what is left in the centres of the leaves. The fruit, too, partakes to some extent of the varied hues of the foliage, and adds materially to the general effect. It is, moreover, edible, but in flavour it is inferior to any of the varieties which are now grown for the sake of their fruit alone.

The cultivation of this variety is by no means difficult; the soil best adapted for it is a mixture of two parts turfy loam, one part peat, and one part leaf-mould and well-decomposed manure, to which should be added a small quantity of silver or sharp river sand. The plants should be potted in spring, but if they are to be placed in vases or other ornamental devices, it is advisable to use somewhat small pots, in order to ensure

their fitting more readily into such receptacles. Where plants are wanted for such purposes, the soil may be made a little richer in quality, to compensate for lack of quantity. After potting they must be grown in a stove, warm frame, or pit, and where a gentle bottom heat is obtainable, they should be plunged into it, in order to induce a rapid development. When sufficiently large, if required for in-door decoration, gradually inure them to a cool temperature, and be careful that cold water does not remain in the crown of the plant. These directions having been followed, the plants will be ready for any use to which the taste of the owner may choose to put them.

Variegated Pine-apple.

When grown to a large size the variegated pine is a striking plant for exhibition purposes, and if it is intended to use it in that way we should advise it to be grown in a brisk heat, with full exposure to sunlight, as by this method the colours are much brighter than in the case of plants which have been subjected to too much shade.

Of the liability of the leaves to get broken when used as a drawing-room ornament, there need be no apprehension. They are always armed, and will take care of themselves. Indeed, the old Scotch motto, "Nobody shall touch me with impunity," has an especial applicability in the case of this plant. W.

THE ARBORETUM.

OLD YEWS.

YEW-TREE VALE, a dell on the chalk downs near the woods of Wotton and the country of Sylva Evelyn, is one of those fine wild parks adorned and planted by nature herself. Here may be found as many as fifty great yew trees grouped together on an uneven slope, permitting no other growth except that of a few attendant hawthorns, with the green turf under foot. The yews stand in, what is called in America, an "opening," or wood pasture. Around is a game preserve, with a liberal growth of furzes, hollies, junipers, and lesser yews. It is undoubtedly part of the primeval forest, untouched as yet by culture, or even by any chance hand "sticking in a tree"; for everything that grows on this retired site is indigenous. The lesser native evergreens, the butcher's broom, ivy, and mistletoe, are freely sprinkled around; so are the oak, ash, birch, elder, maple, hazel, crab, bullace, and sloe, and the usual hedge-fruits.

The bow has been cut in Yew-Tree Vale, Druidical rites may have been celebrated here, and the golden knife may have sliced the mistletoe from the predecessors of these old thorns. The place has an aspect of Ancient Britain, and its silent repose seems to plead against revolution and deprecate change. May none attempt to beautify its ancient face, and desecrate the vale by introducing any novelty within its precincts!

Many of the trees are now in the vigour of old age such as yews enjoy. One at least has grown younger in appearance, and has

now more life in wood, bark, branch, and leaf than it had twenty years ago, when accident induced that singular effort of rejuvenescence which the yew can exert so powerfully, and which the short-lived fir is incapable of making. A fire was lighted in the hollow of a tree which had stood for many years previously green and grand, and firmly supported by a strong outer shell of wood. Twenty years later the charred marks had disappeared, and at the exposed edges, wherever nature could work, a new growth of bark and wood had repaired the damage, and given the intended victim a stronger hold of life, and, mechanically, a firmer support than it had on the day of the outrage, with a greener growth overhead, and an abundant crop of branches breaking out on the repaired trunk.

Many of the old yews have formerly parted with a slab from their bulging trunks, that has, perhaps, been worked up by shepherds and others into nut-crackers, cups, and little keepsakes, which have had a value, small or great, in the villages round for these hundreds of years. It is curious to see how the hardy giants have patiently repaired the ravages of this rude carpentry by enveloping the section with a new growth gradually overlaying the excised surface. In some instances, an unhealed portion shows the old wood underneath marked by the tool, and evincing by its decay that the robbery of the plank must have occurred hundreds of years ago. There are trees that would be thought sound but for the scars and eyelet-holes, which reveal a mass of decaying wood behind. Occasionally the marvellous power of life produces a new stem from the root, which grows up through the dying parent, nourished by the mould formed by a mass of rotten wood, dead leaves, remains of roosting birds, and dead animals. In one instance, a white beam tree has struck root in the decaying material within the hollow, and has carried its stem through the top of the foster parent, where its silvery leaves appear to grow on the yew in glittering contrast to the sombre hue of the ancient evergreen.

The decay of the wood within, and the cracking of the weakened boughs in "windy storms," is the beginning of the end. The next stage is a hollow tree; then perhaps a fire; then reparation; then several more hundred years, till the outer shell and vestige of a trunk is broken by wilful violence, or by sheep and deer rubbing against the time-honoured remains, or striving to enter the hollow for shelter. Then comes utter decrepitude; limbs fall and tear down part of their perishing support, and at last the venerable ruin is rendered to the dust from which it gathered life and strength so long.

Any visitor of Surrey scenes wishing to find out these patriarchs of the yew-tree family may inquire the way to the narrow race-course, or to Newland's Corner, a noted meet for hounds; and the first shepherd he may chance to meet will lead him to the less notorious spot he seeks.

H. NEWLANDS.

THE COMMON LAUREL A USURPER.

THERE is no plant perhaps that deserves the title of "usurper" more than what is generally called the common laurel. No doubt this fine, free-growing evergreen is one of the most desirable of shrubs when kept in its appropriate place, viz., where it has ample space—in large shrubberies, or under trees on the margins of woods and copses, or flanking the carriage drive and boundary fence; for nothing can be better as a dense low background, a shelter from winds, or a screen from unsightly objects and buildings, offices, &c.

In accordance with the ordinary ideas of gardening, this shrub is the first obtained from the nursery, as it is also the cheapest, to adorn the approach to the dwelling or the limited garden at the rear. Placed usually in the very front of the border, and quite close to the walk, it grows most rapidly into a vigorous shrub, its shoots often attaining in a single season to three, four, or even five feet in length. It is impossible to exaggerate the evil of which this rampant shrub has been the cause; the smaller conifers, such as thujae, junipers, and delicate cypresses, as well as bay, laurustinus, arbutus, rhododendrons, and roses, and other refined and compact shrubs, are constantly found to be quite hidden or destroyed by its wealth of shoots. I must confess that I have enjoyed the utmost satisfaction in ordering hundreds to be cut down and carted away, thus not only developing to the view many better things, but opening the finest vistas and distract peeps of scenery, and have rejoiced in many a "bravo" and outburst of thanks for this bold and liberal application of the handbill, saw, and hatchet. The term "usurper," however, has yet to be explained; this vaunted, self-called laurel is really no laurel at all; he usurps the name only from the old Celtic word "blaur" or "laur," or "green;" it is simply a species of cherry (*Prunus Laurocerasus*), and has no right to trench upon the classical, noble family of "*Laurus*," which without doubt is one of the most valuable genera in the vegetable kingdom, being spicy, warm, fragrant, and medicinal. The species include *Laurus nobilis*, or sweet bay; *L. cinnamomum*,

L. Sassafras, L. Camphora, L. Cassia, and many others. These are true laurels, and it is to be regretted that not more than two are hardy in Britain, one of these only (the bay) being evergreen. It is high time, then, that this false-nomenclature as regards the common laurel should be set right, and the term "cherry laurel," or "evergreen cherry," be given to this ordinary though ornamental shrub. The leaves are believed to be poisonous even to cattle, but the panicles of small black fruit it bears are sweet, and not unpleasant to the taste. They are especially appreciated by tramps of the gipsy community. One word in justice to, and appreciation of, this "cherry laurel." Its large, oblong, glossy leaves, of the finest golden green, contrast admirably with the more sombre, deep tones of the Portugal laurel (also a *Prunus*), the bay, holly, &c. And here it may be well to name that the Alexandrian laurel is not a true *Laurus*, but a *Ruscus*—*R. racemosus* or *R. alexandrinus*—and is presumed to be the plant with which the ancient poets were adorned, while heroes and victors were crowned with the bay (*Laurus nobilis*).—E. W. Cooke, *Glen Andred*, in "Field."

THE WALNUT (JUGLANS REGIA).

THIS is comparatively but little planted, a singular fact when the beauty and value of its wood are taken into account. For gun stocks and much of our finer sorts of furniture, Walnut timber is invaluable. Walnuts, moreover, are free growing trees on almost all kinds of soil, and the crops of nuts which they produce would pay at least the rent of the land on which they grow, while its freehold might be purchased with trees of four score years of age. Walnuts in a landscape also are trees of mark, their magnificient heads of fine foliage in parks or paddocks rendering them especially adapted for such situations. They associate well with Oak, Beech, Elm, Spanish and Horse Chestnut, as well as with various other trees, and they do not rob the land more than their companions do. Their smooth glossy leaves are washed clean with every shower, and the foliage is not so thick as to throw the rain off the grass or to keep air currents from circulating freely among the branches. There are, therefore, no trees either in park or pasture under which herbage grows better than it does under Walnuts.

Besides, Walnuts come into leaf late, make their growth quickly, and lose their foliage nearly all at once, after the first autumn frost. Thus a chance is given to take the leaves out of the way, so as not to injure the grass; while the shining dark young wood, with the greyish mature limbs are left full in view. As to any tree that will grow more quickly into a size to be useful, I do not know where to look for it. I have seen old Walnut trees that measured from sixty to ninety feet in height—diameter of branches from six to ninety-six feet, and of bole or trunk, from three to five feet diameter; and, no doubt, larger trees are elsewhere to be found.

Considering, therefore, all its good qualities, what can be the reason that Walnuts are not more extensively cultivated in this country than they are? Is it because young folks will sometimes pillage a few nuts, rather than spend their cash in the purchase of French walnuts? Surely not. That the French grow walnuts more extensively than we do is certain; they find, too, a market amongst us for their nuts, which, had we more trees, we might with advantage share with them.

JAMES BARNES.

Phillyreas, Bays, Arbutus, Thujas, Junipers, &c., they are quite at home. These, together with Laburnums, purple Beeches, and scarlet-crimson and yellow Horse-Chestnuts, Judas trees, Sumachs, &c., are the materials with which ornamental grounds cannot well be overstocked.—JAMES BARNES.

The Lombardy Poplar (*Populus fastigiata*.)—This fast-growing pyramidal tree is not so fashionable with planters now as in years gone by. About a century ago no plantation was made without it, and for shutting out unsightly buildings, &c., in the landscape, it was considered invaluable. Even now it may to a limited extent be introduced into plantations of round-headed trees, to give them life and interest, especially when looked at from a distance, its pointed head producing a pleasing contrast to its less aspiring companions. This effect is more particularly apparent in Cheshire, Worcestershire, Herefordshire, Gloucestershire, and Somersetsire, than in other counties. It associates well with old churchyards, cemeteries, old ruins, amongst pointed-headed cypresses and yews; a plant or two of it has also a homely look at the entrance to a village, or it may be on its green. At the same time it would be out of place to plant this poplar largely anywhere except where it is wanted to plant out straight objects.—JAMES BARNES.

The Poplar.—The beauty of Poplars in autumn is far more noteworthy when numbers of trees are taken together than in any single specimen. Sometimes the mountain-ash fades to a splendid red colour and is very beautiful in itself, but it is very uncertain, and one specimen will do so while another will not. The white poplar, however, is the most beautiful common tree in this respect (common), I have said, but it is not half or a quarter common enough as yet. The golden poplar is also very beautiful, and is more common, but of weaker tones of yellow till you come to the youngest, which have their own imitable pearly sheen in the most bewitching contrast with the yellow in the middle of the tree; the great openness of the foliage in this tree also allows a full light to pass through it so as to show it up to the best advantage. By all means plant white poplars on the windy side of your garden. Afterwards, ordinary planes will do better, and the outline of the tree so soft and sweet.—D. D.

"In small proportions we just beauties see"—Not only these broad and stately effects, but to get a picture of fisherman's wood, or to find scenery come within the domain of landscape art, but those lesser and ordinary graces that may be compassed within stone's throw of a road. We do not measure an artist by the width of his canvas. The pano...as that take in mountains are well if the life and mist of the mountains are in them; but they do not blind us to the merit of a cabin gem. I question very much if there is any apprehension of the finer beauties which may be made to appear about a given forest, or about a picture of a pond, or a meadow, or in the management of a three or five-acre lawn than upon such reach of meadow and upland as bounds the view. The watchful eye for a single hoary boulder that lifts its scared and lichenized hulk out of a sweet level of greenward; the audacious protection of some wild vine flinging its tendrils carelessly over a bit of wall, girl with a savage hedge-growth—these are indications of an artist's feeling. I like the riotous as it were, on a bare acre of ground, as I do now; but I have a preference for a picture of a garden, where such judicious adjustment of a few flowering plants upon a window-shelf, and such tender and judicious care for the little mites of turf around which the gravel path sweeps to its door, as showed as keen and artistic sense of the beauties of nature, and of the way in which they may be ennobled for human gratification, as could be set forth in a park of a thousand acres.—D. G. Mitchell.

TABLE OF MEASUREMENTS OF HEIGHT AND CIRCUMFERENCE OF SEQUOIAS IN THE CALAVERAS GROVE.

The Upright Cypress.—In England this Cypress is recorded to have been growing in gardens early in 1500, since which time it has been planted in almost every shrubbery, and it is still deservedly a favourite with most people. I have never seen *C. sempervirens* in this country much above sixty feet in height; but trees of this size are by no means scarce. There are several varieties of it as regards habit, all of which are useful and highly ornamental. They grow freely, and will succeed almost anywhere and on any kind of soil, but they always start best associated with common shrubs planted pretty freely as nurses, to be cut away or thinned out in due season in order to give space both for root and branch; when fully grown, they seed freely, and with us, in Devonshire, the wood is both durable and useful when converted into house furniture, harps, and other musical instruments, resisting as it does the worm and moth. As to growth, I like to see all plants of noble port with a foot or two of clear bole at the base. Cypresses are not expected to make grand effects in the background of free-growing trees; they are more fitted for planting near the front, or as single trees on grass, or in and about cemeteries, &c. They form striking contrasts with buildings, especially with such as have horizontal roofs; but they will not withstand the smoke of large cities. Cypresses are not vigorous-growing enough to plant among large trees, but with such things as Thorns, Crabs, Amelanchier, Yews, Hollies, Portugal Laurels, Illexes, Cotoneasters, Laurustinus, double blossomed Furze,

PUBLIC GARDENS.

WHAT TO DO WITH HAMPSTEAD HEATH.

The wisest desire we have heard for a long time expressed in connection with a place of this nature is the one attributed to Mr. Le Breton and the inhabitants of Hampstead that their heath should be preserved intact, not "laid out" as a park, formal or otherwise. On Hampstead Heath, notwithstanding its hideous fields of gravel pits and other mutilations, nature is even now more delightful than in our most elaborate parks. Till very recently, London was begirt with a chain of airy commons, which offered many attractions to the botanist and entomologist, though that charm is fast decreasing in the case of Wimbledon and Hampstead. Even yet, however, a bit of sundew may be picked up on Hampstead Heath, while briar and furze hold free sway over hundreds of acres; and one may yet find little lawns with carpet of turf soft as velvet, and fringed with graceful high ferns. Some of us are too apt to assume that the more common or heath type of vegetation is one only fitted to be exterminated by the "improver." But when we understand these things better, we shall find that the efforts of the landscape-gardener must be devoted to preserving what we now too often ruthlessly destroy. There are many spots on Hampstead superior to those we artificially create, and with the added charm of utter wildness. If those entrusted with the care of Hampstead Heath insist that all its wild charms be preserved, they will have made an important step in true landscape gardening. A network of trim roads and walks would be a poor substitute for its wide pathways of velvety turf. The slimy-dug borders of the central parks of London are hateful beside its graceful mixtures of bracken, briar, furze, and thorn.

But preserving all its natural beauty should not prevent us from enriching it. This may be done without injuring it or formalizing it in the least degree. There are many spots in it which it would be pure vandalism to disturb; but there are also many where a sprinkling of hardy-flowering deciduous trees, or a group of the hardiest and noblest evergreen trees, would lend a variety and a beauty which would charm all beholders. Wherever the gravel-digger has been very busy, we must follow, and with some trouble re-embellish the earth he has defaced. It is often possible for the tasteful landscape-gardener to take much advantage of disfigurements of this kind, and by a little grading and careful planting, to render them much prettier and more diversified than before they were created. Without costly planting, or planting that will cause any trouble, or require any attention when once finished, we may get the highest beauty that may be obtained from rolling ground, green grass, and beautiful trees. And what park in existence offers scenes that might be charmingly embellished by tasteful planting more than Hampstead Heath?

For proof of how much such embellishment would gratify and exalt the taste of the people we are left in little doubt by the weird group of *Pinus sylvestris* (Scotch pine) on Hampstead Heath. Some of our best artists have introduced them into their pictures, and they are well known in our literature. There is nothing in any of the London parks so beautiful as this group of Scotch fir, which has taken care of itself for long years unguarded; and surely where such a gratifying result comes from the planting of *one* kind of tree one need hardly plead for the judicious planting of other kinds? This may be carried out without in the least interfering with the wild beauty of the heath. By the time the pines which have delighted the present generation of artists and tree-lovers begin to decay, a score of groups of other noble trees should be arriving at maturity. It is folly to leave a piece of ground so well calculated as Hampstead Heath for the display of tree beauty an almost treeless waste. It is almost needless to add that the planting advocated need not involve any "laying out" of the ground, but simply the placing of suitable hardy trees in carefully-selected positions. The groups would require a fence for a few years; afterwards they would require no more attention or protection than the Scotch firs have. A trifling expense would suffice for the purchase and planting of the best trees for the purpose.

Other great and peculiar charms might be added to Hamp-

stead Heath by the naturalization of hardy flowers, which would multiply freely and grow healthfully in such a position. There are numbers of charming hardy flowers, such as the daffodils, the blue anemone (*A. apennina*), the globe flowers, wood hyacinths, snowdrop, crocuses, &c., which would be as much at home on the heath as the bracken and the furze. Such as these might be bought cheaply in quantity, dotted about in the short grass and about low wild shrubs, and the result in a few years would be a vast wild spring and early summer garden surpassing all that art in "tum gardens" has yet effected.

FLOWERS AND FOUNTAINS.

BY NOEL HUMPHREYS.

THE two fountains in Trafalgar Square have been so severely, to say unmercifully, criticised, that condemnation need not be reiterated. They are already in possession of the unenviable distinction of being the best-abused fountains in Europe, and it will only now be necessary to allude, in some detail, to their admitted meagreness and nakedness of aspect, in order to point out the more clearly how those defects might be alleviated, if not even partially obliterated.

The most magnificent and, on the whole, the most successful of modern designs for town fountains of a strictly decorative character on a grand scale, are indubitably those of the Place de la Concorde at Paris. But even they have a certain indefinable defect—a kind of frigidity or baronness, which, by means analogous to those about to be proposed for the improvement of our comparatively puny structures in Trafalgar Square, might easily be overcome. In pointing out that there is a something still wanting to the compleat decorative success of the great fountains of the Place de la Concorde, it must not be imagined for a moment that it is sought to depreciate the stately and truly artistic merits of these fine works, which, for their important features of colossal statuary, combined with ornamentation that in itself reaches the level of high art, are certainly not to be approached in excellence by any similar works of recent construction in any part of Europe.

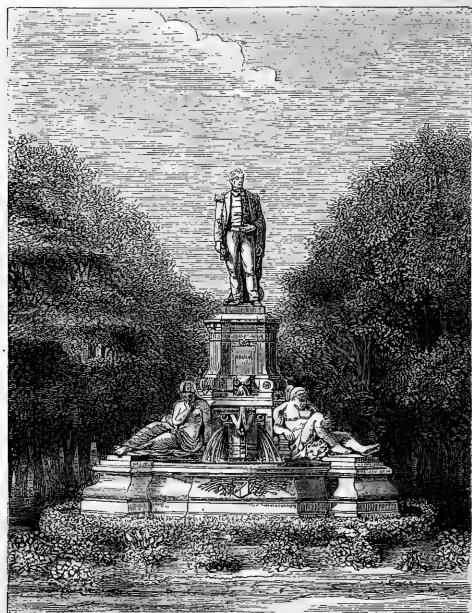

The French have, in fact, been the only nation in the nineteenth century whose artists have succeeded in laying hands on the true artistic principles which necessarily govern the general forms as well as the minor enrichments properly belonging to the class of structures at present under discussion.

Many other examples of French success in this department of art might be cited, which form spicidul ornaments to several of the great provincial towns of France, but it will suffice to mention one only, a fountain serving as a magnificent base and pedestal to the statue of Bruat (see next page), which the writer saw and sketched a few months before the late deplorable war. Bruat, who was one of the brilliant and successful leaders of the First Empire, was a native of Colmar, and the monument erected to his memory by his townsmen, is, in every respect, a very nobly- devised and finely-executed work. The principal mass of the structure supporting the statue consists of four richly-sculptured basins, separated by four symbolic figures of colossal dimensions and of great merit as pieces of high-class sculpture. The artistic treatment of these grandly designed figures might, however, be pronounced by a certain class of critics as "thoroughly French"; though they undoubtedly produce a fine effect, which is the chief object in architectonic sculpture. Moreover, the "drawing" of these grand figures is artistically and anatomically correct, which cannot always be said of works which have the supposed merit of greater sobriety and severity of treatment. The bold and largely-conceived mouldings, and the rich masses of incidental ornamentation also, although but minor features in the composition, are very skilfully and grandly traced, by the hand of a true master of his art; being as superior to those which belong to the base of the Nelson Monument in Trafalgar Square, or to those of the adjacent fountains, as it is possible to conceive. The whole composition is the work of M. Auguste Berthold, a young sculptor, who resides at an old family chateau, which nestles among a rich mass of ancient trees, not far from Colmar, in preference to entering the troubled artistic atmosphere of Paris or any other great city. He has thus determined, as I learnt, to carry on the enthusiastic pursuit of his art undisturbed among the woods of his native Alsace.

It may be urged by cavillers, in depreciation of many of the characteristics of French art generally, that all the best features in many of the noble fountains that have been erected during the present century in various parts of France have been borrowed from Italian models. That may be very true, for in the general style, in the disposition of parts, and in the noble sculpture of the fountains of the Place de la Concorde, the French artists were evidently inspired by the exquisite piece of fountain-work which was designed by

Giovanni di Bologna for the Piazza Vecchia at Florence; and in all probability M. Berthold had also seen and studied Bernini's famous fountain on the Piazza Navonna at Rome, before he designed the structure which is one of the greatest ornaments of Colmar. But, while admitting this, it must be confessed at the same time that such French artists have invariably stamped their works with the distinctive genius of their own age and country, and that their productions have a well-knit compactness and completeness seldom to be found in their Italian models.

The Bruat statue-fountain stands at the entrance of the public gardens, and is therefore backed by the rich greens of great masses of foliage, the dark tones of which form a background against which

The Bruat Statue-Fountain at Colmar.

the outlines of the various marbles define themselves with excellent effect—the sculptured outline of the base being immediately surrounded by a dwarf edging of a low-growing evergreen shrub, while symmetrical masses of richly-tinted flowers form additions of living colour, which have the effect of enlarging the base of the structure and imparting additional importance to its aspect, and, at the same time, softening the sharply-cut forms of the marble into the surrounding space, and warming the general effect by the addition of a *floral framework*, the absence of which is one of the chief causes of the naked coldness of aspect of our fountains in Trafalgar Square. Those fountains have other inherent defects in regard to the situation they occupy, which cannot very well be mended without their absolute removal, and the replacing of them by larger and better works; for, in the first place, they are on too small a scale, and consequently have a meanness of aspect, which no improvements or surroundings can entirely overcome; and, secondly, their form, as small tazzas, with an insignificant elevation in the centre, from which the water was originally made to ascend a few feet and then fall in frothy foam, caused them when first erected to be compared to big saucers with bottles of ginger-beer popping off in the middle; the aptness of which ill-natured *mot* caused it to stick to them with such tenacity, in spite of the dignified silence with which the ridicule was submitted to by those chiefly concerned, that it eventually became absolutely necessary to do away with the ginger-beer-bottle effect. To accomplish this, a dozen or so of separate water spoutings were contrived, instead of the single central one. Had these supplemental jets been produced in some picturesque manner, showing their *raison d'être* through

artistic means, the effect would have been as good as could be expected on so small a scale. But the *modus operandi* was entirely inartistic. The leaden squirts through which the jets are thrown up were left plainly visible, no means being sought by figure, shell, vase, or any other device, to secure an agreeable and pictorial effect and produce a decorative out-shoot for the water; so that when the fountains are not playing, these ugly, black excrescences are in the highest degree unsightly.

Our niggardly grants for purposes of a purely decorative character were, perhaps, insufficient either for an entire reconstruction of the fountains on a large scale, with enrichments of high-class sculpture, or even for clothing the projecting pipes with some artistic device, however simple, by way of rendering them worthy rivals of the Fontaine Louvois (engraved below).

There is, however, a means by which the extreme nakedness and chilly aspect of these, our only metropolitan fountains of a decorative character, might be very considerably abated. All who take an interest in such matters, and who do not pass over with closed mental eyes the changes and daily-varying aspects of our vast city, must have witnessed with satisfaction the temporary improvement wrought upon the dingy desolation of Trafalgar Square by the recent introduction of a few tolerably well-grown Bay trees during the summer months. A touch of living colour is ever-refreshing in the highest degree; and had the tree been bigger and more numerous, the inevitable result of an experiment of that kind would have been very charming, though far from fulfilling all that a love of the stately and beautiful in such an important and central situation might desire. But, at all events, the plan essayed was in the direction which the writer of this article wishes to recommend, with the view of imparting a more cheerful aspect to that dull, black expanse of flag pavement, which a very competent authority once pronounced to be the finest site in Europe for art purposes, and which might still be made a very noble and attractive area, if properly treated.

The plan recommended is simply this: Let a portion of the present pavement be taken up round the basins in which the fountains stand. Let a finely-designed moulding, dwarf but massive, surround the basins at the distance of a certain number of feet, and let the form of the enclosure correspond symmetrically, but not regularly, with that of the basins. The space between the basins and the new enclosure should then be turf'd, and in the turf there should be well-designed flower-beds, which, during the whole of the spring, summer, and autumn—that is to say, from the Crocus season to that of Chrysanthemums—should be filled with bold and richly-coloured plants. Few will be found to deny that a very pleasing and satisfactory effect might be produced in this manner at comparatively small

Fountain in the Place Louvois.

expense, especially if the same principle were resorted to round the base of the Nelson Column and in front of the terrace wall of the National Gallery. In the last-named situation the Bay trees, duly supported by the fresh green of an expanse of turf, would produce ten times the effect they have hitherto done when placed separately on the dark, un congenial pavement.

It may be urged that turf and flowers will scarcely thrive as might be desired so close to the dense and smoky neighbourhood of the Strand, St. Martin's Lane, and the crowded masses of sooty brick-work which form the antifloriger region known by the name of Seven Dials. In reply to this objection it is to be remarked, by way of answer, that many of the old City churchyards, especially that of St. Andrew's, Holborn, and that of St. Sepulchre, at the corner of

the Old Bailey, as well as several which are situated in the dark and narrow lanes of the very heart of London, have already been transformed from recesses of mouldy blackness into flower and shrub-studded spaces of refreshing green; and that the plants flourish sufficiently well to convey an air of pleasantness to spots which were depressingly desolate before. The inference therefore is, that in the comparatively open space of Trafalgar Square, turf, shrubs, and plants, with occasional renewals, would thrive sufficiently well for all the purposes sought by their introduction, and would form a very pleasing addition to the present nakedness and repellent frigidity of the fountains. With regard to the fountains themselves, a great improvement might be effected, at small cost, by getting rid of all the unsightly squirt-pipes, and doubling the supply of water to be emitted from a single aperture. The increased supply of water ought to be cast up to a much greater height than that attained by the present vertical jets, and it should issue from a handsomely-designed columnar opening much higher than the present one. This increased supply of water might then be made to fall in a copious cascade into a secondary tazza at a well-calculated elevation above the lower one, from which it should be made to descend, in an unbroken glassy sheet of glistening gossamer-like texture, to the spacious basin below, which might be enriched very advantageously in the introduction of masses of water plants symmetrically distributed.

A few hydraulic difficulties might be set up by opponents to such a scheme; or the expense might be objected to; but difficulties of that kind might be very easily, and even cheaply, got over; and it is to be hoped that all who delight in witnessing the creation of such embellishments for our metropolis as will place it more upon a par with other great cities in its ornamental features, may, even as early as next spring, be called upon to admire such improvements of the so-called "finest site in Europe," as will make it more worthy of that high sounding designation.

THE INFLUENCE OF OUR PUBLIC GARDENS.

As the young artist looks to Italy for models and for inspiration so look numbers of untravelled amateurs and gardeners to our great National Gardens, and hence a reason why their true character and importance, as regards the art of laying out grounds, should be widely known throughout the land. The chief public gardens of a country must have a powerful influence on its private ones, and it is most unfortunate that with us this influence can rarely be anything but injurious to all the true interests of garden design. Most of our public gardens and parks are designed in direct violation of the very essentials of the art of laying out grounds; many of them show precisely what to avoid, and though this merit is not alluded to in their guide-books, it may, to one who rightly uses it, be of greater importance than any other feature. Descending or ascending to particulars, let us glance at a few of our public places. Look at Kew, in some respects superior to any botanic garden or botanical establishment in the world, but in point of design no higher than a chess-board. That breadth—*i.e.*, an open spread of lawn here and there—is the most essential principle in garden design one would think was known to everybody who ever thought of arranging or planting a public garden or park. Without this, you cannot get any but a confused effect—you cannot fully see the beauty and dignity of our now rich arboreal flora; without that you may have a thousand kinds of noble trees, and get little better effect than you do in a large unthinned plantation. You can, in fact, not make a really beautiful garden or park without at least one sweet spread of open, turf-y ground than you can a lake without water. At Kew, both in general design and in the arrangement of details, this principle is completely ignored, and the good old-one of putting in a tree wherever there is a little opening adopted. The result is that the finest botanic garden in the world is devoid of any picturesque beauty. As to the Paris botanic garden it is infinitely worse; there, not only is all the breadth destroyed, but even the very turf has gone!

Take, again, the Royal Horticultural Society's garden at South Kensington, and, leaving out of view entirely the question of style, assume that the geometrical is the only one. This garden was specially designed for flower-shows and for the reception of crowds. Now, if there has been any one thing taught by all previous experience of large flower-shows and the gardens in which they have been held, it has been that the happiest effect is only attained where there is a quiet open lawn on which crowds can promenade at pleasure, and pass from it with ease to the various important points of interest in the garden. And what has been done to meet this want? The design is the most complicated one we have ever seen even for a geometrical garden. Every place where a bit of turf might have spread out to form a foreground, or a setting for the different objects which a garden should contain, is frittered away—here a maze (what an idiotic adjunct to any public garden ranking above that of a

tea-house!); there a short avenue of Lombardy poplars cutting off the view, for no evident reason; beyond, placed on a bank, lest its lovely effect should be lost, a fire-shovel pattern wrought on the earth, with all the beds filled with broken stone-rubbish of various colours. In short, there is no room anywhere except on parched and wearying gravel walks. At every step a sensitive person who visits the garden in the hope of seeing trees or plants or flowers is offended by a sickly low-clipped yew hedge, a dead wall, a flight of steps, a ghastly corridor, or one of the many contrivances by which nature is shut out from the scene; and if a prize had been offered for the very worst kind of garden in which to enjoy a flower-show or plants or trees of any kind, a garden more fitted to win it could scarcely have been designed. In this case, however, the deviation from the right course was so marked that it is not likely to be so harmful, as the manifold contortions of the scene disgusted even the admirers of the style; and since the finishing of this unhappy garden there have been much fewer gardens of the same style made in connection with country houses.

The only one public garden that betrays any judgment or insight into what a garden should be is the small garden of the Royal Botanic Society in the Regent's Park. We speak not of its collections, which are poor, nor of its gardening, but simply of its design when we say that if the judgment which has done so much with eighteen level acres had been equally successful with the vast surfaces in some of our public gardens, they would be models indeed. The Botanic Garden in the Regent's Park is disfigured by absurd conglomerations of rock, by a still more absurd small geometrical garden; but in point of general design it has helped to keep a true spirit of landscape gardening from slumbering among us during one of the most marked periods of retrogression that it has ever lived through. I mean the period of the success of those who preferred the presence of barbarous artificial things in the most important parts of our gardens to Nature's own children, of which we shall never weary—who often spent sufficient wherewith to plant a thousand acres with the noblest trees in the world on a water-squirting contrivance, who, where we wanted peace and variety, gave us the monotony that dulls the sensitive spirit, and the angularity and barbarous gyrations that torture it—wretched so callous to every mercy of nature, and so estranged from all passion of joy in her works, that, when we asked for flowers, they gave us broken bricks and slates, arranged in patterns by their miserable "art." We could name gardens of from five to twenty acres in extent near London and in the home counties which display more merit as regards plan than all the public gardens in Britain put together. Plants and trees and flowers, no matter how disposed, fail not to charm the wearied, dust-pested citizen; but it cannot be too widely known to all interested in horticulture that there is NO GOOD DESIGN IN OUR NATIONAL BOTANICAL AND HORTICULTURAL GARDENS.—Field.

PALMS FOR THE GARDEN.

(Continued from page 93.)

C. CALAMUS ADSPERSUS (*syn. C. gutta*: Java).—Fronds, erect, clothed with nearly black spines, arranged in whorls of from nine to ten at base. The whole plant has a dark-green hue, and is very spiny. A strong grower, and very elegant where a central plant is required for a water-tank.

C. asperimus (*Java*).—Plant, erect, and clothed with yellow spines irregularly disposed; top of leaflets gracefully drooping; grows from sixteen to twenty feet in height, and forms a dense bush. A very elegant, free-growing palm, of a yellowish tint.

C. ciliaris (*Java*).—Dwarf, and erect; when three feet high the fronds are a foot long and six inches wide, grey; spines very slender, pale green; pinnae dense; very compact, and feathery—in fact, the gem of the genus, and very desirable for table decoration where a small plant is required, or for intermixing with orchids for the sake of contrast.

C. deprespusculis (*Java*).—Plant, dense; fronds, compact and spreading; spines on petiole, small, light brown; young plants furnished with fronds, eighteen inches long and eight inches wide, almost flat. A very distinct.

C. flagellum (*Assam*).—Fronds, six feet long; pinnae, distant; spines, yellowish. A plant of lax growth, and not very useful in the way of decoration.

C. leptopadix (*Java*).—A very elegant slender-stemmed palm; fronds, flat and short; pinnae, dense; spines, few, brown; the whole plant velvety in appearance, very compact, producing fronds at intervals of four inches apart. One of the best of palms for table decoration.

C. (Damonoporus) Lewisianus (*Penang*).—Plant erect, slightly spreading at top; fronds, from six to eight feet long; spines, yellow. An exceedingly elegant free-growing species for the general

decoration of large houses. *C. Jenkinsii* is so very like this plant, that whoever has the one does not require the other.

C. (Draenoropis) melanochetus (Java).—A strong useful plant, with dark shining foliage and habit compact; spines, few; fronds, from two to four feet long, dense.

C. montanus.—Under this name seed was received at Kew from Ootacamund, but the name is a somewhat doubtful one. Though said to be a cool-house palm, it appears to be very fond of heat.

C. pachystemonus (Java).—A tall, free-growing plant with broad pinnae; spines, long and pale. Where a plant is required to run quickly up the corner of a house, this may be of use, otherwise it possesses little value.

C. Rotang (Bengal).—When young a spreading graceful palm, with dark-green foliage; pinnae, long, distant; spines, few, black. A plant variously named in gardens, but readily distinguished by its black spines and dark foliage; when old it gets lax in growth.

C. Roxburghii (India).—Fronds, spreading; rather lax; dark green; spines, brown, few. Not one of the best of palms.

C. tenuis (Java).—A slender, erect plant; foliage, sparse; spines, few. A distinct palm but not very handsome.

C. trichrous (Sumatra).—Fronds, erect, forming a beautiful plume at top; habit, dense; spines, yellowish. A very good plant for table decoration.

C. viminalis (Java).—Plant dwarf, flowering* at three feet in height; stem, slender, yielding offsets freely; fronds, spreading, two feet long; spines, yellow, small. A very beautiful, useful-sized plant for a small house.

(To be continued.)

J. CROUCHER.

THE AMATEURS' REMEMBRANCE.*

In-Door Department.—In greenhouses or small conservatories a low, equal temperature must be maintained; and now, when there is little attraction in the way of flowers out of doors, no effort should be spared to have Camellias, Azaleas, Roses, Dutzias, Sweet Indian Daphnes, Cinerarias, Chinese Primulas, Cyclamens, &c., brought forward in as fine condition as possible. Among these perhaps none excites so much interest as the Rose, of which a few well-rooted, carefully-prepared plants in pots may now be placed in gentle heat, and forced steadily, for Roses dislike a high temperature. They should be syringed every morning, along with other inmates of the forcing-pit in a growing state; and as soon as they get fairly into leaf, aphides and rose-grubs must be kept in check—the first by tobacco fumigations, the second by means of hand-picking. Otherwise carefully attend to them; but never allow either Roses or other plants to open their blooms in the forcing-pit. When they approach that condition, remove them to the conservatory or other show house which they are destined to ornament. During winter all plants in pots should be watered in the morning, and except in the forcing-pit, everything should be kept on the side of dryness, to prevent damp and disease. Give air whenever favourable to plants in masses, removing the sashes altogether in the middle of sunny days from such things as Carnations, Pinks, or Asters, but in rainy weather keep them on, tilted back and front: Where Vines are not already pruned, that operation should now be performed without delay. After which, having well mulched the border, the house should be shut up for forcing.

Flower-Garden and Shrubberies.—With the exception of a Christmas Rose or two, we have had little to interest us in the way of flowers, since the Tritomas and Michaelmas Daises left us; but on walls we shall soon have Chimonanthus grandiflorus, the blossoms of which when gathered are highly prized in-doors on account of their fragrance. The Jasminum nudiflorum will also soon be opening everywhere its bright blossoms, which, when issuing from among Ivy leaves, have a cheerful appearance. With these and other evidences of floral life, lawns smoothly rolled, and clean and comfortable walks, out-door gardens even now afford a certain amount of real enjoyment. Evergreens overgrowing the bounds assigned to them may still be cut back, but the pruning of the tender kinds of Roses and other shrubs likely to be hurt by frost had better be deferred till spring. Planting and alterations in the way of ground work, should now be finished with as little delay as possible.

Fruit and Kitchen Garden.—While open weather lasts push forward pruning and railing. Orchard trees, often too much neglected, should have their heads opened up a little by cutting out all ill-placed branches, and such as cross one another. If not already done, mulch all root-pruned or newly-planted trees with rich, partially-decomposed manure. Clear wall and other trees from insectests, and stake and name such as are in need of such operations. Mulch Strawberries with rough stable dung, shaking it lightly over both plants and alleys. Its strength washed down to the roots, is of much benefit to the plants, while the strawy portion left affords them protection. In the Kitchen-Garden, manuring and trenching must now be pushed forward with vigour. Peas peeping through the ground pricked with spruce branches in the event of frost. Broccoli may also still be taken up, and put in closely together where it can at any time receive protection, or it may be pulled up and hung by the heels in some shed or cellar out of the reach of frost. Cauliflower plants should now have plenty of air. Stir the ground among Cabbages, Spinach, and similar crops. Examine Potato and Onion

stores to see that nothing is going wrong, and continue to take up Rhubarb and Seakale, and place them in darkness in gentle heat to force. Sweep and roll walks, and maintain as much interest as it is possible to keep up at this dead season of the year. Stable dung and leaves may now be thrown together to ferment for cucumber and other hotbeds. When fermentation shall have become active, turn the heap over once or twice to permit its rank heat and steam to escape before making up the bed.

THE FOOD OF PLANTS.*

You know that wood is capable of being burned entirely away, with the exception of a small, almost insignificant residue of white ash which is left. This is the mineral matter of the wood, from the circumstance of its being of the same nature as the matter of which our most common rocks and minerals are composed; whereas that portion of the wood which burns away is called the organic matter, from its being the matter of which the living plant is mainly constituted. When wood is exposed to heat—by being thrust into the fire, for example—it gives off gases which burn with flame. Now, where wood is subjected to heat, and more particularly to the hot flame of the burning gases surrounding it, it becomes blackened, or charred, or converted into charcoal. The same principle is made use of in the production of charcoal for manufacturing purposes. When manufacturers want to produce charcoal, they resort to one or other of two principal methods. One of these is to heat the wood to redness in an iron box or oven, entirely excluded from the air, with the exception of a pipe allowing the gases to escape; and after these gases have been driven off through the pipe, nothing is found left in the iron box or oven but a quantity of charcoal. Another way of making charcoal consists in piling the wood up into a large heap, and setting fire to it. By this means the outside wood, in contact with the air, gets burnt away to a greater or less extent; but the inside wood, being simply heated by the burning which is taking place upon the outside of the heap, does not get burnt away, but gives off its gases which burn on the outside; and what is left in the inside is charcoal, produced by the action of heat upon wood out of the access of air. Now, if you examine a piece of charcoal, it will be found to have lost both size and weight compared with the original wood. But you will observe that the resulting charcoal presents exactly the form of the original piece of wood. The conclusion, therefore, is that wood is a substance partly composed of charcoal; or, in other words, that charcoal is one of the constituents of wood. Charcoal may be said to be an impure form of carbon, and, in practical effect, if not in actual fact, carbon is a simple substance. It is a substance which has not yet been decomposed, and is not, so far as our present knowledge goes, decomposable into two or more different kinds of substance. Now, charcoal is not only a constituent of wood, but also of hay and corn, and, indeed, of vegetable produce generally.

But it is important that we should know, not only that vegetable produce, wood, hay, and corn, contain charcoal, but that we should be able also to form some notion of the amount of charcoal or carbon which they contain. Now, it is found that pure, dry, woody matter contains very nearly half its weight of carbon. It contains in reality forty-five per cent. Now, if we pass from pure woody matter to the consideration of other forms of vegetable produce—such, for instance, as starch—we find that that contains exactly the same proportion of charcoal as woody matter, and that sugar contains very nearly the same proportion. But some other vegetable substances contain a much larger proportion of charcoal, as, for instance, resin and turpentine, and the oils expressed from seeds and fruits, as linseed oil, cabbage-seed oil, and olive oil, &c. All these substances contain a much larger proportion of carbon than is contained in wood. Now, just as certain vegetable products contain more carbon than wood, so there are other products which contain less; and among these I may refer to the different acids, or sour substances, which are found more particularly in the juices of unripe fruit. There, for example, is a fine specimen of tartaric acid—an acid which exists in the juice of the grape, and is produced on a large scale, in wine-growing countries, in the process of converting

* Abstract of a lecture delivered by Professor Odling, F.R.S., in the Hulme Town Hall, Manchester, November 24, 1871.

* Complete general calendars, written by some of the most able gardeners in the country, are published in THE GARDEN in the first issue in each month.

grape-juice into wine. In the same way we meet with citric acid in the juice of lemons, and other vegetable acids in other vegetable juices. Now, all these vegetable acids contain a smaller proportion of carbon than is contained in wood. But having regard to the fact that the great mass of vegetable produce is composed of woody matter, or of substances such as starch and sugar, having substantially the same composition as wood; and having regard, further, to the circumstance that, of other vegetable products, some of them contain a larger, and some of them a smaller, proportion of carbon than is contained in wood, it results that the amount of carbon contained in woody matter may be taken as a fair representative of the amount of carbon contained in vegetable produce generally, viewed as a whole. We may say, then, that the dry organic substance of a growing plant contains, on an average, about 45 parts in 100, or rather less than half of its weight of charcoal. Now it is found that on an acre of meadow land, or arable land, or wood land, there are produced in the course of a single season several thousand pounds weight of vegetable produce, containing not unfrequently as much as two thousand pounds weight of charcoal; while the charcoal of an average crop may be taken at over 1,600 pounds, or nearly three-quarters of a ton per acre. Some notion may, therefore, be formed of the large amounts of charcoal or carbon accumulated somehow in vegetable produce. And when we pass to the consideration of vegetation, not as we see it here, but as it manifests itself in the luxuriant growth of tropical climates, the amounts of produce, and, consequently of carbon contained in the produce, become yet more astounding. Humboldt, among his experiences in South America, records the existence there of forests so huge and so thick, that monkeys might run on the tops of the trees for a hundred miles in a straight line without a single break. And the millions of tons of dry wood, capable of being furnished by these forests, are composed, we know, to the extent of nearly half their weight of charcoal! You perceive, then, that the growing plant, whether large or small, tree of the forest or grass of the field, may be regarded by us simply as a contrivance for producing carbon.

In the case of cereals or other crops that are grown in a single season, it is evident that we remove from the land at the end of the season several thousand pounds weight of vegetable produce which did not exist in the form of vegetable produce a few short months previously. Nevertheless, the actual substance, or weight of matter, constituting this produce must have existed before the growth of the crop, although in a very different form. The several thousand pounds weight of wheat and barley and oats, grown on an acre of land in a single season, were not produced out of nothing; but were produced out of many thousand pounds weight of something pre-existing at the beginning of the season in the form of certain very different kinds of matter, out of which this matter of wheat and barley and oats was somehow constituted. In the same manner, when, in course of time, the acorn grows into a tall oak-tree, the several tons of matter which go to compose the woody tissue of the full-grown oak were not produced out of nothing, but out of many tons of matter which existed, though in a different form, before the acorn was ever planted; and which have been accumulated, and transformed into woody matter, by the plant or tree, during the period of its many years' growth. For the matter or substance of which the grown oak is finally composed was not furnished by the acorn, but was furnished to the acorn, or young plant springing from the acorn, by external and very different forms of pre-existing matter. The problem, then, which I wish to put is this, what is the external matter or substance out of which the matter of wheat and barley and oats and hay and wood is ultimately produced? And more particularly, what is the sufficiently abundant substance containing carbon, out of which the carbon of all this vegetable produce is accumulated? for I need scarcely say that this carbon can only be got from some substance already containing carbon. Iron can only be produced from iron-stone, or matter containing iron; copper can only be produced from copper ore, or matter containing copper; and in the same way it is evident that the carbon of vegetable produce can only be obtained from matter containing carbon. What, then, is the primitive matter containing

carbon, out of which, in the course of the growth of the plant, this carbon of vegetable matter is ultimately produced? It is well known that in forest lands there exists a large amount of rich vegetable mould, the produce mainly of the decay of leaves; and this vegetable mould, which has received the name of "humus," is found to be exceedingly rich in carbon. Further, richly carbonaceous vegetable matter of much the same kind is found in a sort of grass turf; and again, matter of a not dissimilar kind is commonly added to arable land in the form of farmyard manure. Now, until about thirty years ago, the prevalent notion was that the carbon of vegetable produce was furnished to the plant by the carbonaceous matter of the soil called humus, or by a matter of a similar nature. The vegetable matter of the growing plant was conceived to be formed out of pre-existing vegetable matter; and plants, like animals, were thus supposed to live upon food more or less resembling in composition the tissues or parts of the plants and animals respectively nourished. Now, notwithstanding the inadequacy of this notion, and notwithstanding its discordance with well-known facts, and with facts that had been for a long time well known, it prevailed for very many years almost without question. About thirty or more years ago, however, the consideration of eminent agricultural chemists both in England and in France was directed to this view of the subject, and very serious doubts of its truthfulness began to be entertained. But the notion was not ultimately exploded until the year 1840, by the celebrated German chemist, Liebig. Now, I do not propose to advert to all the arguments which may be employed to show the inadequacy of this humus theory to account for the accumulation of carbon in plants; but I will direct attention to some of the most prominent reasons only. First, it is probable that in certain rich soils there does exist an amount of humus, or such like vegetable matter, containing a quantity of carbon sufficient to furnish the crop grown upon the soil with the carbon which it ultimately contains. But this vegetable humus is exceedingly insoluble in water; and Liebig made the curious calculation, that if all the rain that falls upon the land during the period of the growth of the crop were to remain upon the land, and to dissolve as much of this humus matter as it is capable of dissolving, so as to become thoroughly saturated with humus; and then, if all this water so saturated with humus, instead of draining away, as we know that most of it does, and evaporating from the surface, as we know much of it does—if all of this so saturated water were absorbed into the tissues of the plants, nevertheless there could not be dissolved in this water, and so supplied to the plant, a sufficient quantity of humus to furnish the quantity of carbon ultimately found in the crop. This, of course, does not amount to a demonstration that the plant cannot get its carbon from the humus of the soil; it is only a demonstration that the plant cannot get its carbon from this humus by the only process of absorption of which we have any knowledge; and, accordingly, it comes to this, that if plants do acquire their carbon from humus, they must get it therefrom in a manner with which we are totally unacquainted. But another argument, and a much more striking one, has reference to the fact, that the carbon of the crop may be increased two-fold, and even three-fold, by adding to the soil matters which contain no carbon whatever.

Messrs. Lawes and Gilbert have found that, taking the average of seventeen years, the gross amount of produce removed from an acre of continuously unmanured land, in the case of wheat, was 2,434 lbs., and that when from this gross produce they subtracted the amounts of water it contained and of ash which it yielded, there remained 1,963 lbs. of dry organic matter; and when they came to analyse these 1,963 lbs. of dry organic matter, they found them to contain 880 lbs. of carbon. And this, mind, is the average produce of seventeen years' continuous growth of wheat, on land to which nothing whatever was added. Now to a similar strip of land the same experimentalists added every year a certain quantity of mineral matter, corresponding to the ashes yielded by each successive crop removed; and on the strip so treated, the amount of gross produce was found to be increased from 2,434 lbs. to 2,912 lbs., the amount of dry organic matter to be increased from 1,963 lbs. to 2,347 lbs.; and the amount of carbon to be increased from 880 lbs to 1,052 lbs. Now to another strip of

land they added year by year exactly the same quantity of mineral matter and, in addition, a considerable quantity of ammonia salts—the ammonia salts and mineral matter being alike absolutely free from carbonaceous organic matter. And in the case of this strip they found, that the amount of gross produce was increased to the surprising extent of 6,394 lbs., while the amount of dry organic matter was increased to 5,149 lbs., and the amount of carbon to 2,308 lbs. These results, it will be observed, are fully as high—in most cases indeed somewhat higher—than are results obtained on a fourth strip of land, supplied year by year with an abundance of farm-yard manure, containing not only the mineral matter and ammonia added to the third strip, but rich also in carbonaceous organic matter. It is inconceivable then that the plant should acquire its carbon from these organic matters of the soil, seeing that the amount of carbon in the crop may be increased twofold, and in some cases nearly threefold, by adding to the soil substances, such as mineral salts and ammonia, which are entirely free from organic matter. It is inconceivable, too, that the original humus in the soil could furnish the carbon contained in a succession of crops for seventeen years consecutively.

Indeed, it is found that many plants flourish best, in a state of nature, upon soils which, if not absolutely free from organic matter, are yet to all intents and purposes free. Thus, according to Darwin, rich harvests of maize are yielded in the interior of Chili and Peru by soils consisting of the merest quicksand, never enriched by manure. According to Colonel Campbell, the soil of the cinnamon gardens, at Colombo, and where else the tree is cultivated, is pure quartz sand, as white as snow. Dr. Schleiden, again, observes that the oil palms of the western coast of Africa are grown in moist sand; and that from the year 1821 to the year 1830 there were exported, as produce of these palm-trees, into England alone, 107,118,000 lbs. of palm-oil, containing 76,000,000 lbs., or 32,000 tons, of carbon, these thousands of tons of carbon being furnished by trees grown in a soil that was practically free from organic or carbonaceous matter of any kind whatever. The only further argument with which I will trouble you is based on the observation that when plants are grown upon soils actually containing organic vegetable matter, so far from this vegetable matter in the soil being used up or decreased by any feeding of plants upon it, it is very much increased; so that the more vegetation we get from the surface, the more humus we get accumulated in the soil; and we say, therefore, that so far from humus being the cause of vegetation, vegetation, on the contrary, is the cause of humus—the humus being produced chiefly by the decay of matter formed by vegetation.

(To be continued.)

which should only be employed for blocking up the entrance to the well, or for thatching the stack; for when straw gets damp, it assists in wasting the ice. I may add that we stored away in our ice-house and stack nearly three hundred cartloads by the middle of November, this season, an early date for so large a quantity.—DAVID CUNNINGHAM, Moor Park, Rickmansworth, Herts.

Rabbit-Proof Plants.—Experience appears to differ considerably on this subject. In THE GARDEN of December 16th and some of the earlier numbers, several plants and shrubs are named as being rabbit-proof, which no rabbits of my acquaintance, at least, have ever manifested a great dislike to in hard times. These are, if I recollect aright, hollies, cotoneasters, roses, mahonias, and the Pampas grass. The first of these they eat up wholesale here, so that we had the greatest difficulty in getting young plants up. Cotoneasters and mahonias they bark unsparsingly. Roses they eat even when their natural food is plentiful, and I have shot them with the bite in their mouth. The Pampas grass they stamp to the ground; indeed, the amount of damage half-a-dozen rabbits will effect during a hard winter would hardly be credited. An experienced woodman of my acquaintance declares that nothing but rhododendrons is safe from them in severe winters.—J. SIMPSON, Worthy Hall Gardens.

The Long-tailed Titmouse.—This is a bird which ought to be cherished by all possessors of fields and gardens, for there is scarcely a more determined enemy to the many noxious insects which destroy fruits, vegetables, and flowers. Fortunately for ourselves, the Long-tailed Titmouse is very fond of various sawflies which work such mischief among our fruit-trees, and often lay waste whole acres of gooseberries; and it is no exaggeration to say that, to a possessor of an orchard or fruit-garden of any kind, every Long-tailed Titmouse is well worth its little weight in gold. When, then, we come to consider the inestimable and unappreciated services which this tiny bird renders to mankind, we should not only be devoid of all gratitude, but likewise of all common sense, were we willing to destroy our feathered benefactor.—Wool's "Homes without Hands."

Bitter Willows as a Game Covert.—For the formation of a game covert which protects the object from the ravages of game, there is hardly any situation in which this plant will not grow, and a good covert would be formed by it in one season, as it puts out abundant shoots, which, in rich bottoms, will attain a height of from seven to thirteen feet in one year's growth. Among other kinds in the S. purpurea group, S. Forsythiana is also an excellent willow for the same purpose; but, although these two willows are well adapted to the backwoods, they grow into tall, slender poles for fences and other uses. They may be reckoned that feathered game has an especial liking for willow plantations, whilst they afford them a more secure protection than any other description of cover. The S. Kerksii is equally secure against the ravages of game, and, although not so vigorous in its growth, still it would be found of more value, in a commercial point of view, where profit is desirable. I should recommend cuttings from three to five feet in length, in preference to rooted plants, as being more easily planted and taking quite as readily, and even more so, on foul and rough land.—*Scutell's "Salix."*

Bees and Brambles.—In October last, while walking in the glen next to Fairlight Glen, on the Hastings side, I picked up a stick about a foot long, and began to break it without looking at it. It broke into fragments very easily, and when about five inches were left I happened to notice it. I found it was a stem of bramble. The whole of the pith was gone, and the space occupied by a number of transparent cocoons, each containing a maggot, such as one finds in an apple, and which, (as far as I can see,) are the pupal stage of the bramble fly end to end, without any interval between them. They were about three-eighths of an inch long by one-eighth in diameter, and of uniform section throughout, so that the maggot did not entirely fill each cocoon. I regret very much that when I left Hastings I forgot to bring the stick away, as I had intended to send it to you. I wrote for, but did not succeed in obtaining, it. Can you tell me the name of the insect? and whether what I have described is its natural habitat?—*Dr. Syme, Fife.*—I have often seen this bee in dead bramble sticks in summer, and always attribute it to the operations of these bees, which, during the previous year, have eaten all the pith out of the shoots when young and succulent.—*Ed. Field.*

Fertilization of Cereals.—I am not aware, says Dr. Syme, in *Journal of Botany*, of any observations on this subject. This year I turned my attention to the question, and, as my residence is in the midst of cornfields, I had ample opportunity of investigating the subject. In wheat and barley the stigmas receive the pollen from the anthers before the latter are protruded, and the exerted anthers I found to be always empty. In the oat most of the protruded anthers are empty, but occasionally anthers with pollen are to be found after protrusion, and stigmas exposed at the sides of the flower have not been able to find in any instance the pollen grains of the Aegyptianum, the Maritimum, and Hordium murinum, maritimum, and bulbosum, protrude their stigmas and unexpanded anthers in the manner usual among the Erythraceae. My observations are confined to the county of Fife, and the case of the oat seems to show that the mode of fertilization is not always constant in the same species, so that observations are required in other places. The question is more important than it appears at first sight. I have noticed letters in the newspapers from farmers, saying that a wheat harvest because the "wind has blown off the flowers." Now, if the anthers may be blown off without affecting the fertilization no harm is done, and the belief of this may save a needless panic and uneasiness for rise in the price of corn.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE GARDEN IN THE HOUSE.

FLOWERS FOR THE DINNER-TABLE.

BY NOEL HUMPHREYS.

I HAVE just seen, in the private dining-room of a London Club, such a display of Orchid blossoms, those gorgeous jewels of the tropics, as made that square, unpretending, gas-lit room a very hall of beauty. No other flowers at once convey to one the impression that we stand in the presence of supreme beauty. They are the floral queens of loveliness, whose charms are unrivalled and undisputed. The very butterflies of their own regions, gorgeous as are the dazzling colours of their painted wings, must cede the palm of beauty to these glorious flowers. Even the golden splendours of Papilio Priamus, and the flashing metallic azure of Morpho Adonis, sink into a secondary rank of beauty as they fit past the wondrous forms and exquisite tints of these unrivalled blossoms. The colouring of the tropic butterfly is glaring and coarse when compared with the pearl-like graduation of the pervading tints of Orchid flowers, and their striking contrast with the purples, crimson, and oranges of their markings. And, then, there is the dainty texture of their exquisitely-formed petals and sepals, often of a flake-like semi-transparent tissue, that leaves far behind the cunningest manipulation of the artistic wax-worker in his vain attempts to imitate their beauties. That pale dead wax makes but a sadly poor and brittle petalage, compared with the flakes of living beauty that form the Orchid flower, which in its sculpture-like vitality is evidently intended to be "a thing of beauty and a joy" for a much longer period than a common flower. It is, in fact, well known that the flowers of many of the most splendid Orchids endure in all the splendour of their loveliness for several weeks among the balmy shades of the deep recesses in which they delight to hold their court of beauty, secure from the disturbance of any invading wind more ruffling than the warm breath of a tropical evening; and where no too ardent sun-ray can intrude till softened down to tender, caressing warmth by the deep veil of interwoven foliage that meets above their bowers.

What a glorious privilege to possess these exquisite creations of nature in our uncongenial climate!—creations, of which it might be said, "the earth bath stars, and these are of them." To be able to command their growth, to time the period of their expansion to an hour, is a triumph of our civilization in which it is very sweet to indulge. The poet Cowper only expresses dimly the refined enjoyments which improved horticultural appliances and the stores of new beauty which the enterprise of our travelling botanists have since brought within our grasp, when he said,—

"Who loves a garden, loves a greenhouse too:
Unconscious of a less propitious clime,
There blooms exotic beauty, warm and sung,
While the winds whistle and the snows descend."

The genuinely flower-loving poet little dreamt what exquisite and entirely novel beauties of the floral world were destined to be placed at our disposition by means of that artificial protection, the results of which so delighted him; and most assuredly he would have been no less astonished than delighted, if he could have seen the display which I have just enjoyed—a display not raised sparingly by such laborious means as would have rendered each flower precious, but produced by sheer horticultural skill, in such lavish abundance as rendered it possible to cut a whole hamperful for the embellishment of a single meal. As the

result of such successful culture, just such a supply was gathered from his private collection by one of our merchant princes, merely to embellish a dinner-table prepared for a comparatively small number of friends—about a dozen—the preparations for whose reception I have just enjoyed the privilege of examining. The table was circular, and in the centre was placed a tall, slender, trumpet-shaped vase of simple glass, twenty-seven inches high, from the mouth of which seemed to be breathed forth, as by some horticultural magie, not delicious sounds, but a cloud-like group of forms and hues—fair and fairy-like, as though they had arisen through that crystal tube from the very spirit-land of flowers. Their forms seemed scarcely those of the flowers of earth, so strange, so weird, and yet so beautiful! so wildly fantastic, yet so exquisitely symmetrical! so chaste and delicate, and yet so gorgeous in their varied tones and tints! Above all the others climbed forth, with a paradoxical angularity of grace, a branching, many-flowered Oncidium; a little lower drooped three elegant sprays of the closely-bloomed Calanthe vestita. Still lower shot brightly forth, bold and sparkling, several of the starlike flowers of Angreacum sesquipedale, from whose brightness seemed to emanate a soft astral light, while the long train-like appendage streaming wildly from them made them look like a constellation of comets about to dart from their spheres. Then came again Calanthes, drooping low in their tender tints of white and violet; then a spray—queen of this bevy of fair flowers!—of the exquisite Phalaenopsis amabilis—a fairy shower of snowflakes, that is to say as to their beauty, but more substantial, more sculptural, not like the snowflake on the lake, white for a moment, and then gone for ever, but created to endure to the very longest limit ordained to floral life, in all its pristine perfection. Then, travelling round the group, came more Calanthe, and another comet constellation of Angreacum, and a huge pendent spray of Epidendrum ciliare, whose sharp intercrossing sepals looked like piled lances, and whose bare and slender flower-stem was hidden by an over-lying and gracefully curving spray of Odontoglossum Alexandre. Other things as rare and as beautiful followed, each coming forth from among feathery fronds of delicate ferns (especially the Maiden-hair), the only kind of foliage, except their own, that the flowers of the Orchid tribe can tolerate association with; but from tufts of this kind of vegetable plumage they seem to issue as congenially as from among the neighbouring greenery of their native dells.

At its base, the trumpet-shaped vase sprang from a shallow crystal saucer, filled with mosses, from the midst of which issued other and larger fern fronds, some reclining gracefully against the slender stem of the vase, and others drooping with a negligent grace on to the snowy table-cloth; a few wandering stems of the climbing Myrsiphyllum asparagoides straggling playfully still further afield. Reposing upon this bed of delicate greenery other Orchids lay, revelling in their beauty. Cattleya exoniensis, Lelia elegans, and several other superb beauties boldly basking in the glare of gaslight as luxuriously as if still growing among the balmy dews and rich warm shadows of their native dells of the prolific tropics; one pale creamy beauty, far beyond all others in loveliness—Odontoglossum Alexandra—exhibiting rich crimson maculations that shone like rubies.

Beyond this central vase and its gorgeous freight of floral magnificence was arranged, circling about the grand central group like a guard of honour, a constellation of lesser vases, each bearing its plume of floral beauty. And this was not yet all the display, for, again, in front of each expected guest was placed a lesser vase, each with its delicate spray of Maiden-hair fern enshrinng a single blossom of some exquisite Orchid—such button-hole bouquets as Covent Garden can only furnish forth sparingly, and at fabulous prices.

Surely, the decoration of our dinner-tables by means of such exquisitely-beautiful natural objects tends to invest even the vulgar charms of turtle and aumontillo with a certain amount of real elegance, and to raise trains of thought above the ordinary level of such occasions; far above the mere materialism of the banquet, towards a more spiritualistic contemplation of some of the most exquisitely beautiful of all created things. The ancients placed roses on the banquet-board not only as a symbol of the brevity of existence, and as expressing in their evanescent beauty the motto, "Enjoy while

ye may," but also with the view of showing that life is not only to be lived, but also to be embellished; and horticulture is evidently one of the many means through which its embellishment may be most advantageously achieved, and by which it may be endowed with beauties of never-ending variety, and its feelings and aspirations perfumed, as it were, with a civilizing and elevating influence.

P.S.—It was intended that a sketch of at least one of the lesser vases, with its Orchid and its fern fronds, grouped by a tasteful and experienced hand, should have accompanied this wandering reverie on Orchid beauty, but the project was given up in despair, as it was found that wood engraving, even of the highest kind, could not convey any adequate idea of the delicate tones of the original flowers.

FLOWERS UNDER ARTIFICIAL LIGHT.

It is a more important matter than at first sight may be apparent to know exactly what flowers are the most effective when seen under the influence of artificial light. Some flowers, as we all know, which are most beautiful in the day-time are dull and dirty-looking at night, and for that reason totally unfit for table decoration. Although this is well known to those who are conversant with the arrangement of flowers for festive occasions, sufficient attention is not, as a rule, paid to the suitability of the various classes of flowers for the purpose, either by the gardener, or those who have the dressing of the épergnes and the filling of the vases, when that work is done by the housekeeper or the lady herself. Too much is left to chance; and, instead of growing a certain number of plants which furnish flowers most suitable for the work, no consideration is paid to the matter until they are wanted, and then the flowers that are most plentiful are gathered and used as best they may be. There is no remedy for this state of things unless those who have the arrangement of the floral decorations know exactly which are the best, and then give instructions accordingly. It is a grave question whether épergnes ought not to be dressed in a room darkened, and then lighted artificially: there would then be fewer mistakes than are now commonly met with. In my opinion, the whole question of dinner-table decoration is in need of reform, especially with reference to the public exhibitions, which, as at present conducted, do but very little towards educating the public in principles of taste, or in showing which are the most suitable flowers for the purpose. Regard ought to be paid to effectiveness when subjected to the influence of artificial light. As at present conducted, these exhibitions do but little good, for the appearance of flowers during the day-time is alone considered, and it is worthy of note that, at the last exhibition of table decorations at the Crystal Palace, the leading prizes were awarded to stands dressed with flowers, which, however light and elegant they appeared at the time, were utterly unfit for the purpose.

The question, then, arises, what flowers are the most suitable? And I will at once proceed to answer it. First of all, it must be said that shades of lilac, blue, mauve, and purple, must be avoided, and preference given to white and various shades of red. Amongst greenhouse plants, many of the Azaleas and Camellias will be found invaluable. Of the former, Admiration, white; Chelisom, scarlet; Comet, scarlet; Fascination, bright rose red; Flag of Truce, double white; Flower of the Day, white, striped carmine; Francis Devos, double scarlet; Grande Duchesse de Bade, scarlet; La Superbe, scarlet; Mars, bright crimson; Reine des Roses, rose carmine; Stanley Anna, rose carmine; Virginals, white. The best of the Camellias are Beau, deep carmine; Chandlier elegans, rose carmine; Countess of Derby, white, flaked carmine; Doncelkatal, red and white; Gem, carmine; Imbricata, red; Jenny Lind, white and rose; Madame Pepin, rose carmine; Queen Victoria, carmine; Victoria Magnosa, deep carmine. Nearly all the Cape Heaths are useful, as also are the Epacris. The best of the latter are Carminata, Eclipse, Hyacinthiflora, H. candidissima, H. carminata, Lady Alice Peel, Miniatia splendens, The Bride, and Viscountess Hill. The white and carmine varieties of Cyclamen persicum are invaluable either for placing upon the table, or for furnishing cut flowers for the épergne or for the little glasses by the side of each guest. The dark rose-flowered varieties are not so good. The Chinese Primulas: crimson and white are both good, as also are the carmine varieties. Dracophyllum gracile, Iamopterophyllum minutissimum, Kotsosanthus. Pelargoniums: all the carmine and white varieties, such as Gauntlet and Blancheur, and the scarlet-flowered zonals. All the scarlet-flowered Salviae and Tropaeolums; Valloota purpurea, the flowers of which are not purple, but scarlet; white garden lilies, especially Lilium eximium and Lancifolium album; Rhynchospernum jasminoides; all fuchsias with red or white tube and sepals may be turned

to account: From the stove we can take all the Achimenes with scarlet flowers—Stella, Scarlet Perfection, and Coccinea being especially good; Achmea fulgens, Aechmella splendens. All the scarlet-flowered Amaryllis; Anthurium Scherzerianum, Aphelandra aurantiaca, A. Rosea, Clerodendron Balfourianum, Epiphyllum truncatum, E. t. aurantiaca, E. t. violaceum, Eucharis amazonica, Euphorbia jacquiniiflora (should be grown in quantity); Gesneria exoniensis; G. refulgens, G. zeyheri splendens; Ixora Colei, I. coccinea superba, I. crocata, I. salicifolia, I. Williamsii; Poisettia pulcherrima. This also should be grown in quantity, for the single bracts intermixed with the other flowers and fern-fronds produce a most brilliant effect. Specimen plants are also invaluable for table decoration. Justicia coccinea and J. speciosa, and Thrysacanthus ruticans, are all useful, the latter being a real gem, and Stephanotis floriformis. Several orchids are useful, especially Cattleya cristata, Barkeria Skinneri, Burlingtonia candida, Calanthe Veitchii, C. veratrifolia, C. vestita. Many of the Cattleyas, Cymbidium eburneum, Cypridium niveum, Dendrobium albo-sanguineum, D. densiflorum album, D. infundibulum, D. moniliforme, D. noble, D. Parishi, D. pulchellum, Epidendrum vitellinum, Goodyera discolor, Lælia anceps, L. albida, Lycaete Skinneri, Odontoglossum Bluntii, Phaius albus, Phalaenopsis amabilis, P. grandiflora. Amongst hardy plants adapted for forcing, mention must be made of Lily of the Valley, Astilbe (*Hoteia*) japonica, Dielytra spectabilis, Double White Narcissus, White and Red Hyacinths, White Lilacs. Hyacinths are very valuable for table decorations if the bells are stripped off the spikes, and used either singly or in bunches of four or five.—W. C., in "Gardeners' Magazine."

THE FOOD OF PLANTS.*

(Concluded from p. 136.)

I HAVE now brought forward not all the arguments which might be adduced, but a sufficient number of them to satisfy you that the quantities of carbon accumulated in the crop or tree are not derived from carbonaceous matter existing in the soil; and seeing, in this way, that the solid substance of the earth does not suffice to furnish the carbon required, our attention is next directed to the water which falls upon the earth as a possible source of all this carbon. Now water—pure water, that is to say—is a substance which itself contains no carbon, and therefore cannot furnish any carbon to the plant. But certain natural waters are found to contain carbon in small quantity. For instance, the drainage water of peat bogs, and land-drainage water in general, contains a certain amount of carbonaceous organic matter derived from the land; but we have already seen that the land does not contain enough of this organic matter to furnish the carbon of vegetation directly, and cannot therefore furnish it indirectly through the intervention of water taking up organic matter from the land. But we find that rain water does contain carbon derived from another source. The rain, in falling through the air, acquires different impurities or additions from the air; and more especially, it takes up a certain carbonaceous constituent of the air, on which I shall have directly to dwell more particularly. And I am not merely speaking of rain which has fallen in great cities like this, and which has become contaminated with carbonaceous soot and smoke of imperfectly burnt coal; but I am speaking of rain wherever it falls, whether on land or ocean, in town or country, at the end of a period of drought when the air is foul; as at the end of a period of wet, when it has been washed clean by continuous showers. Pure water, I have said, is free from carbon. But all water that has been left in contact with the air, and especially water that has been condensed from and fallen through it, contains, in small proportion, a particular definite compound of carbon, namely, carbonic acid, very different indeed in its nature from the indefinite compounds of carbon we have hitherto spoken of under the name of humus and vegetable organic matter. In this way our attention is necessarily directed to the air as a possible source of all the millions of tons of carbon that are accumulated in forest trees and annual crops, growing on extensive areas of land. And although at first sight it must strike us all as being improbable—scarcely, we should think, possible—that any such quantity of solid carbon could be got from the fresh, transparent, intangible, fleeting air, yet, when we consider that upon setting fire to a heap of wood, or of the charcoal produced from wood, and letting it go on burning, it

* Abstract of a Lecture delivered by Professor Odling, F.R.S., in the Ulmle Town Hall, Manchester, November 24, 1871.

is mainly resolved into matters which are dispersed into the air, and are themselves aerial, we begin to perceive that the improbability is not in reality so great as at first it appears. When we burn, however large a quantity of wood, or of the charcoal produced from wood, there is nothing, you know, left behind but an insignificant quantity of ashes; there is no solid body formed; there is no liquid body formed; there is nothing but an aerial body formed, which is discharged into the air. Now this aerial body used actually to be called air—fixed air, to distinguish it from ordinary atmospheric air—but it is nowadays called carbonic acid gas. This gas is possessed of many curious properties; but is more especially characterised by two. The first of these is the property which it has of extinguishing flame. Another is that it combines with lime to produce carbonate of lime or chalk. Now lime is a substance which dissolves in water to form a clear transparent liquid; but chalk will not dissolve in water. When carbonic acid exists in a large proportion, it has the property of rendering lime-water milky and also, as I have said, of extinguishing flame; but when the proportion of carbonic acid is not sufficient to extinguish flame, we are able, nevertheless, to recognise its presence by the property it has of converting clear lime water into an opaque white mixture of chalk and water. Now I have stated that the aerial substance into which solid charcoal was converted, when it underwent the process of being burnt in air, was carbonic acid gas, which is a compound of carbon with the aerial or gaseous substance, oxygen; and that when carbon or charcoal burns in ordinary air, it unites with the oxygen of the air to form the aerial substance, carbonic acid gas, which is discharged into the air. But although the air does, beyond question, contain carbon in the form of carbonic acid, the proportion that it contains is exceedingly small, not more than four parts in ten thousand. A room twenty-five feet long, as much broad, and sixteen feet high, would hold 10,000 cubic feet of air, containing four cubic feet of carbonic acid gas. And these four cubic feet would weigh 2,465 grains, and contain 607 grains of charcoal—that is to say a quantity of charcoal about the size of an egg. And when we pass from the consideration of air in rooms, to that of the air pressing everywhere upon the surface of the earth, we shall get to results great almost beyond conception. It is well known that the weight of air overlying every square inch of the earth's surface is fifteen pounds. Now, fifteen pounds on the square inch is 2,160 lbs. on the square foot; so that every square foot of the earth's surface has overlying it 2,160 lbs. of air, and these 2,160 lbs. of air contain about $1\frac{1}{2}$ lbs. of carbonic acid gas, equivalent to very nearly half a pound of carbon. I have shown that there are produced, in many cases, from an acre of land, some 2,000 lbs. of carbon in a single season. Now, reckoning from feet to acres, we find that not merely at the first instant of the growth of the crop, but that during every instant of the period of its growth—at the end no less than at the beginning—there is overlying the acre of land furnishing those 2,000 lbs. of carbon some 20,000 lbs. of carbon in the form of carbonic acid, existing, though in such small proportion, in the air. Calculating in this way, we find that the amount of carbon existing in the atmosphere, in the form of carbonic acid gas, is not only enormous in its absolute quantity, but that it is far in excess of the wants of vegetation, and far in excess, moreover, of the quantities of carbon contained in all living beings, both plants and animals, existing on the surface of the earth, and in inflammable carbonaceous minerals, such as coal, which exist buried beneath the surface. In this way, then, we come to the conclusion that by their contact with the air, plants are at any rate afforded the opportunity of getting that carbon, which constitutes so large a proportion of their structure. The question now is, do they avail themselves of the opportunity afforded them? do they actually absorb carbonic acid gas from the atmosphere, and extract the carbon of the gas which they absorb? The evidence on this point dates from the latter end of the last century; when it was ascertained by the older chemical philosophers, and more particularly Dr. Priestley, and by Saussure and Sennebier, that when growing plants are exposed, under the influence of sunlight, to air containing carbonic acid, they do as a matter of fact absorb some of this carbonic acid; and, that having absorbed it, they do not discharge it again into the air, but instead discharge only its one constituent oxygen; the

necessary inference being that its other constituent, carbon, is retained in their tissues. Of late years, the subject has been investigated with great care and elaboration by the French chemist Boussingault, who has shown not merely that plants have this property of absorbing carbonic acid from the air, and of discharging the constituent oxygen of the gas into the air and retaining the constituent carbon of the gas in their tissues, but that they do this with extreme rapidity. In the case of some oleander leaves, enclosed in a glass globe he found, by measuring the leaves and analyzing the air passing over them, that under exposure to sunlight there was an absorption of carbonic acid from the air at the rate of $56\frac{1}{2}$ cubic inches, or a fixation of carbon at the rate of $11\frac{1}{2}$ grains per hour per square yard of leaf surface exposed, showing the extreme rapidity with which the absorption of carbonic acid from the air and the retention of its carbon actually took place. Moreover, he made a great number of other experiments, which established not merely the general fact that plants can absorb carbonic acid gas from the air, and can discharge the oxygen and retain the carbon of the gas so absorbed; but, operating with seeds, and more particularly with peas and vetches, and growing them in artificial soils quite free from carbon, he found that the entire weight of the carbon ultimately accumulated in the grown plant was identical with the weight of carbon contained in the carbonic acid gas which the growing plant had absorbed from, and the oxygen of which alone it had discharged back into, the atmosphere. In this way, then, Boussingault established the important fact that plants acquire their carbon from the carbonic acid of the abundant ever-changing air in which they are grown.

We have thus considered the source from which the carbon of vegetation is obtained. But we have yet another point, and that is—what becomes of it? Now, a little consideration will show that just as the carbon of vegetation is produced from the aerial substance, carbonic acid gas, so the destiny, if I may so say, of the carbon of vegetation is to be reconverted into this same aerial substance. First of all, let us see what becomes of the most abundant of vegetable products, namely, wood. You know that a great deal of fresh wood is put to no intermediate use, but is at once chopped up for the fire; and when this wood is burned, its carbon combines with the oxygen of the air, and is so re-converted into carbonic acid. Again, a considerable quantity of wood is manufactured into charcoal, and this charcoal is then burned and so converted into carbonic acid. And with regard to the diverse applications of wood, we know that much of it is made into furniture, and that this furniture does not last for ever, but finds its way from the best rooms to the attics, and at last to the fire-place. Wood is also used for the building of ships and in the construction of houses; but in course of time the ships get broken up and the houses get pulled down, and the wood of both ships and houses becomes ultimately sold for firewood, and then the carbon of this wood gets burnt into the very carbonic acid from which it was long years before produced. In other cases the wood or woody matter, although it never undergoes a process of actual burning, nevertheless undergoes an equivalent process of oxidation. At the present season, or but very recently, we had large falls of autumn leaves, and those leaves are still accumulated in many places, and undergoing not burning but decay. Now the process of decay consists really in a slow combination of the carbon of the leaves with the oxygen of the air, whereby carbonic acid is produced. Indeed, woody matter of all kinds exposed to the weather, to the action that is of air and water, gradually undergoes decay or oxidation, and, if left to itself, crumbles away, and in course of time disappears altogether, being converted into the invisible aerial matter carbonic acid. When we pass from the consideration of wood to that of the hay and grain eaten by different classes of animals, and mark what becomes of all this food, we shall find that so much of it as is both eaten and made part of the blood and substance of the vegetable-feeding animal, undergoes one or other of two principal changes. A large portion of it gets oxidised in the body of the vegetable-feeder, with production of carbonic acid discharged principally from the lungs in the act of respiration. Another portion gets accumulated in his body, whereby it is fattened and rendered fit to become the food of the flesh-feeder. And when the flesh-feeding animal eats up

the bodies of the vegetable-feeders, their vegetable derived fat and lean that becomes assimilated in his body is found to suffer there a speedy oxidation. Therefore, in the case of food consumed in our bodies, as in the case of wood consumed on our fires, the carbon of vegetable produce is directly or indirectly converted back into the aerial carbonic acid from which it was originally formed. The conversion of carbon into carbonic acid, on the fire, is a burning process, attended with the evolution of heat. The conversion of carbonic acid into carbon and oxygen, in the tissues of a growing plant under the influence of the sun's rays, is an unburning process attended, not with an evolution of heat, but with an absorption of heat from the solar rays: and it follows that there is just as much disappearance of solar heat in the production of the charcoal, as there is evolution of heat in the ultimate combustion of the charcoal produced. So that, you see, the quantity of heat which the charcoal eventually gives out in burning on the fire, is the exact equivalent of the quantity of solar heat which disappeared in the act of growth of the wood, from which the charcoal furnishing our fire was obtained. From what has been said it will be seen, too, that plants derive their carbon from the air rather than from the soil in which they grow.

THE TWO PATHS.

THE NEW GARDENS AT ROCHESTER CASTLE.

A very wholesome feeling in favour of public parks and gardens has fairly set in, and, to say nothing of the metropolis, one after another of our great provincial towns has already provided itself with one or more such places of healthful recreation. The arboretum at Derby, planted some thirty years ago upon land presented to that town by the munificence of Mr. Strutt, the friend and patron of Loudon, who superintended the plantation, must already have become a well-timbered park, though still in the youth of its arboreal existence. Zoological or botanical gardens are already old-established institutions at Manchester, Liverpool, Birmingham, and other great centres of commercial activity. The noble ruins of Dudley Castle have long since been planted about with shrubberies, now well grown, and containing many finely developed trees. From the shady walks of those shrubberies, promenades emerge upon a plain of undulating green sward—untrimmed and unbordered by the innovation of gravel walks, in the midst of which rises the magnificent ruin, just as it might have appeared twelve months after the rude marks of destruction dealt upon it by Cromwell had been freshly clothed by nature with a mantle of tender green, to hide the cruel devastation. When the authorities of the city of Rochester wisely determined, in the beginning of last year, to treat the enclosure surrounding the magnificent shell of the grand old Norman Keep as a public promenade, after the same good fashion as Dudley, for the benefit and recreation of the inhabitants of their ancient city, they certainly took the proper course in advertising for competitive designs for the best plans for laying out the area in question. Prizes of forty pounds each were offered to the authors of the two best designs; and twenty pounds to the third. These prizes offered for plans which only admitted of the most simple treatment ought to have been sufficient to secure the services of the most competent horticultural artists; but the result does not seem to prove that such was the case.

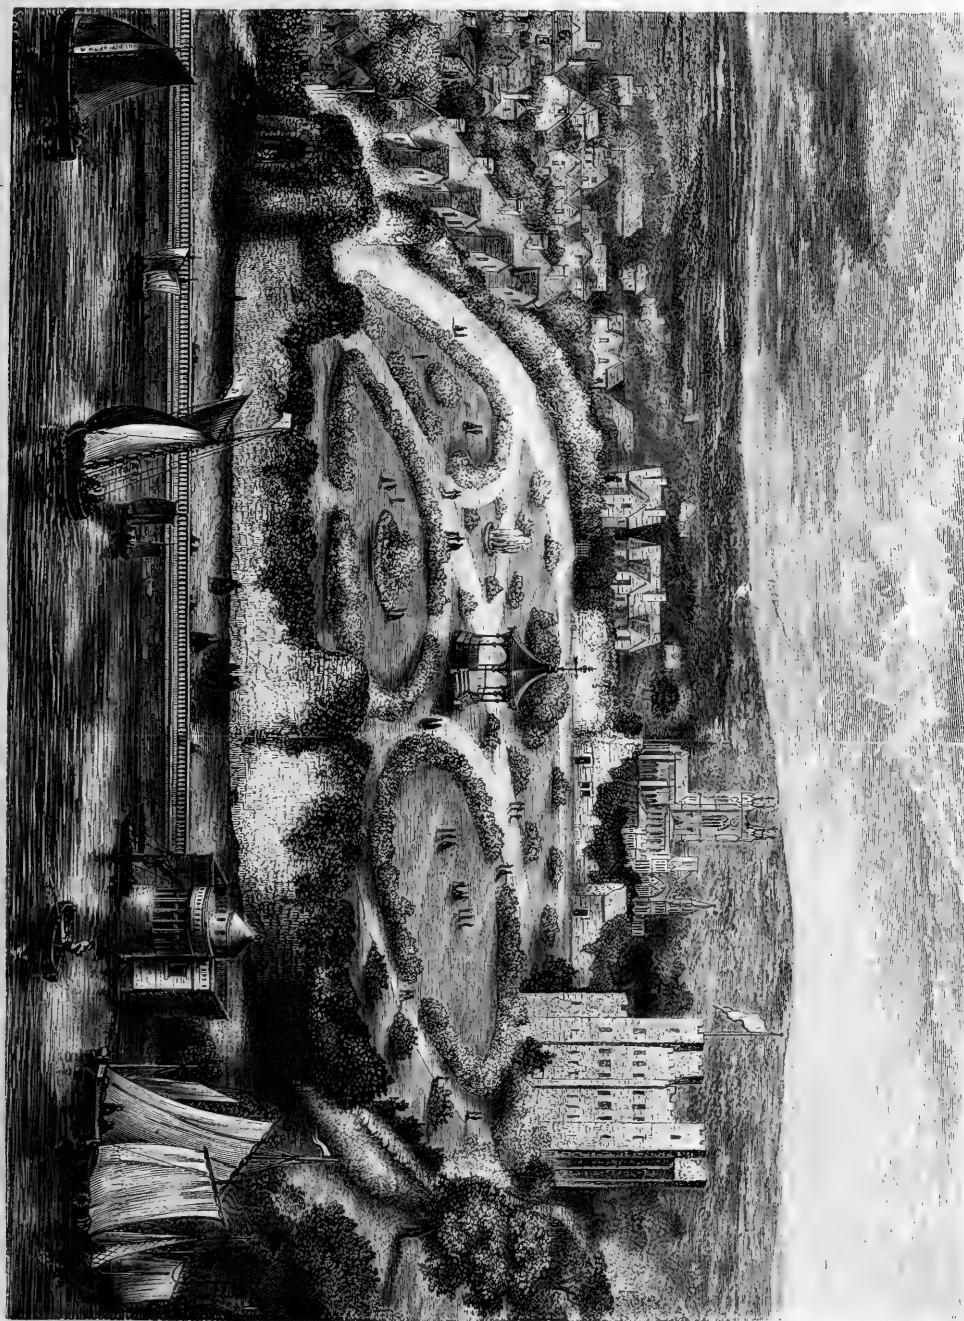

What number of designs were sent in I have no means of knowing; but I learn from the columns of the *Builder* that six were selected from the bulk, as the best; from which, three were nominated to prizes. The one selected for adoption was marked, "Norman," in the competition, and was the work of gentlemen, who, being architects and surveyors, do not seem to have possessed the requisite qualifications for the picturesque

laying out of gardens and the planting of them with suitable trees, selected with taste and care from the abundant arboreal stores now at command. That the qualifications of ordinary architects and surveyors fits them for this kind of work seems plainly open to doubt. But the plan engraved in the *Builder*, and which we reproduce in a manner well adapted to do the fullest justice to the design in question, sets all doubt upon the subject at rest; for anything more bald, unimaginative, inappropriate, and tasteless could not be imagined. In no respect does the plan rise above such an one as might have been furnished for a suburban tea-garden by an intelligent labouring gardener; and thought suggests that it must have been meant for Rosherville, rather than for Rochester. It has indeed all the commonplace vulgarity suited to such a purpose. A Chinese pavilion for a brass band is placed in the middle, and meaningless walks, leading nowhere in particular, cut up the whole surface; utterly destroying the breadth and repose which ought to characterize such a site. Surely, nothing could have been devised by the utmost stretch of descriptive ingenuity more calculated to destroy every association connected with the history of the place, and utterly disgust every visitor of taste and feeling who may in future visit a spot hallowed by one of the most remarkable of the still existing monuments of the feudal story of Britain. One is tempted to inquire how many other designs were sent in—whether twenty, forty, or sixty, and whether they were openly exhibited, in order that the public and the press might have the opportunity of expressing their opinions before the final selection was made. It is the more probable that the drawings were never openly exhibited at all; or, not till some small official conclave had made its own private selection of the plan to be adopted; for it is almost impossible to conceive that, among a number of designs sent in, something infinitely better than the wretched plan adopted could not have been found.

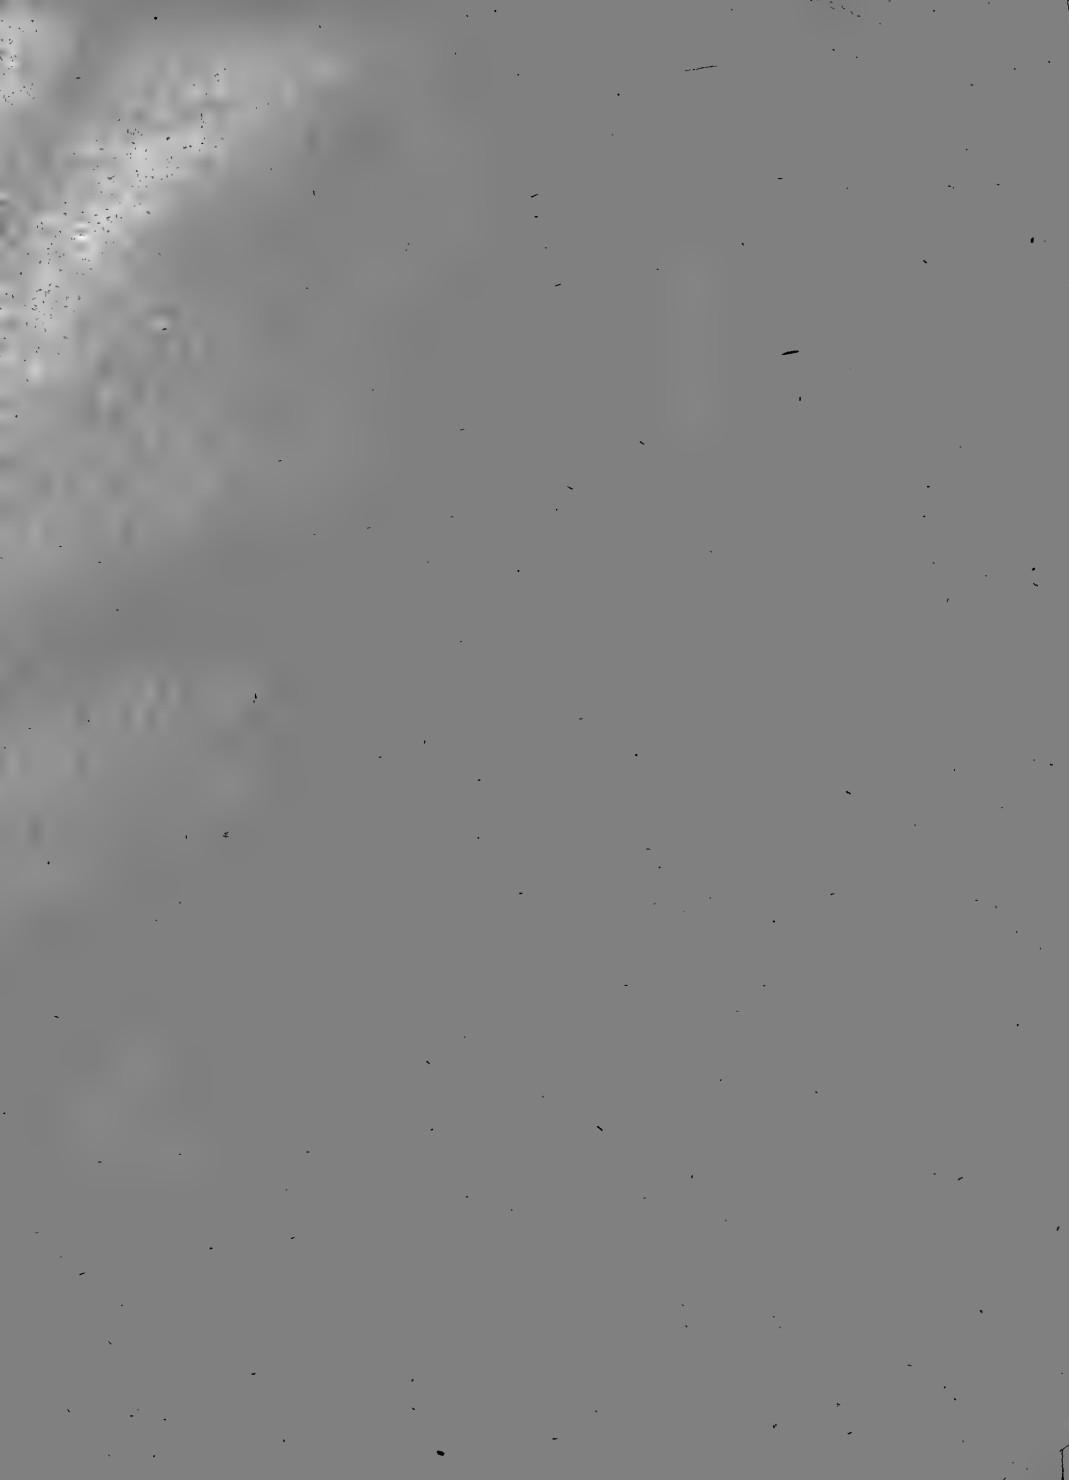

Not to dwell upon the unpleasant subject of the proposed plan, nor to indulge in regrets for many better ones that may have been rejected, it may be well to consider briefly what ought to have been the manner of laying out and planting this plot of historic ground. It rises finely above the broad waters of the Medway, crowned at its highest point by the grand old castle and its round-arched window-openings, which are still in many places nearly perfect, even to their crisp sculpture, so characteristic of those arts of nearly eight hundred years ago, of which Rochester Castle is a noble remnant. That ancient fortalice, in its hoar antiquity, and with its venerable beard of grizzled lichen, still erect in its baronial grandeur, is scarcely second in interest to the noble pile at Warwick, against the vulgar restoration of which Mr. Ruskin has written such noble words, or even the stately remnants of Kenilworth, with all their associated romance. It is most certainly not second in interest to the grand ruin at Dudley; and in throwing freely open to the public the ancient turf-clothed slopes that surround it the greatest care should be taken not to disfigure and vulgarise the historic site by common-place gimcracks; and by such sadly prosaic treatment, of the true tea-garden school, as are exhibited in the accepted plan.

Those venerable slopes should be but very tenderly, very affectionately, and very sparingly, touched by art of any kind; and the art which is permitted to approach them should be of a very high class—the *ars celare artem*. That *sot-disant* art of the glaring kind, which dashes itself insolently at the eye, like an offensive intruder, as it always is, should be kept entirely aloof, at any cost. With this view, the whole of the central space (disfigured in the plan by the trumpery band-stand) should be kept broadly and grandly open, and undisturbed, except by the planting of a few, very few, choice trees, destined to become large and striking objects, either singly or in groups of three or five. In every other respect the expanse of turf should remain unbroken; obtrusive gravel walks, with trimmed edges, would be utterly destructive of the calm repose which should pervade such a scene.

A single pathway, partially concealed with shrubs of various kinds, chiefly evergreens, might extend around the interior circuit of the enclosure for some two-thirds of the distance from the entrance, in the direction of the castle; but the occasional openings should be wide and clear, commanding, in some

THE WRONG PATH.—THE NEW "PRIZE" GARDEN AT ROCHESTER CASTLE.

places, uninterrupted views across the open green, and in others fine glimpses of the castle from different points of view.—As to flower-beds and flower planting, in the ordinary sense, there should be none of it. All must be strictly a nature garden; and nature, left alone, does her garden work exceedingly well. Over the broken walls of our ruined abbeys and castles she has hung, with unerring grace, her glistening mantle of ivy; not cropping its fringes either with the aid of the mechanic's straightedge or gardener's peg-line. And then she leaves portions of the hoary masonry free from the ivy-woven scarf, in order that, at sunny angles, she may plant in the crumbling crevices seeds of the golden wallflower, to shed its perfume over the scene of venerable decay, and that she may suspend graceful tufts of the creeping antirrhinum from certain joints of the dislocated stonework; while along the ridge of the ancient parapets she plants its more ambitious congener, the greater snapdragon, whose bold spikes of pink or crimson flowers form a gorgeous crest-work to old ruined walls. Rochester, too, has long been celebrated for an exceptional and elegant addition to nature's ordinary wall furniture; those old battlements being known as one of the few spots in England where the wild carnation is found; and many an enthusiastic field botanist has made a devout pilgrimage to the ancient castle of the Medway to gather specimens, destined to be long cherished among the choicest treasures of his herbarium.

Those ancient flower-wreathed walls, and the window-gaps in the great square keep—those "loops of time," whose crumbling sills have been long since replaced by mingled masses of flowers and ferns—should be allowed to give the key-note to the floral treatment of the green space of the enclosure. Hollows, in suitable aspects, may be naturally carpeted with primroses and wood anemones; others with blue bells, mingling tints with purple squills; while towering foxgloves, purple, white, and grey, may contrast their hues with the yellow and orange of the wild linaria on bright and sunny banks. And then, huge clumps of the pale golden daffodil might be made to light up the deeper parts of shadowy dells, and many other delightful natural features might be developed by careful, and not obtrusive, art. In short, nature may be aided, in the setting forth of her fair display, in such a manner as to conceal the aid afforded. Thus, wallflower and antirrhinum seed may be freely sprinkled in the crevices and along the ridges of the walls, and nature may be safely left to rear such of her numerous progeny as she chooses, while rejecting others; just as, after the thick planting of primroses, blue bells, foxgloves, and other of the queens of our native flora in what appear to be the most suitable spots, nature may be left alone, to extend or diminish the colonies so planted according to her own good grace, ever unerringly guided by the suitableness of the situation and the soil. So treated, the ground about Rochester Castle may be filled with attractions of an elevating character, that will be in sweet and reposeful accordance with the scene of noble ruin. But, cut up in the glaring fashion of the tea-garden horticulture exhibited by the published design, it will become a desecration to the spirit of the place, and a disgrace to the city authorities, who permit the perpetration of such a vulgar piece of atrocity.

H. N. H.

[If Rochester wants a Rosherville, there cannot be the slightest objection; but, in the name of good taste, do not let it be made within the precincts of the glorious old Castle. The illustration will enable the reader to judge of this piece of "prize" garden design. The chief vices of "landscape-gardening" are well shown in it. The scarcity of tastefully-designed gardens in private places need puzzle us no longer, when a beautiful piece of ground, in one of the most hallowed spots in England, is thus violated. As an example of the true course to be pursued in such a case, we may point out the quiet and beautiful garden surrounding the Abbey and Roman ruins at York.—CONDUCTOR.]

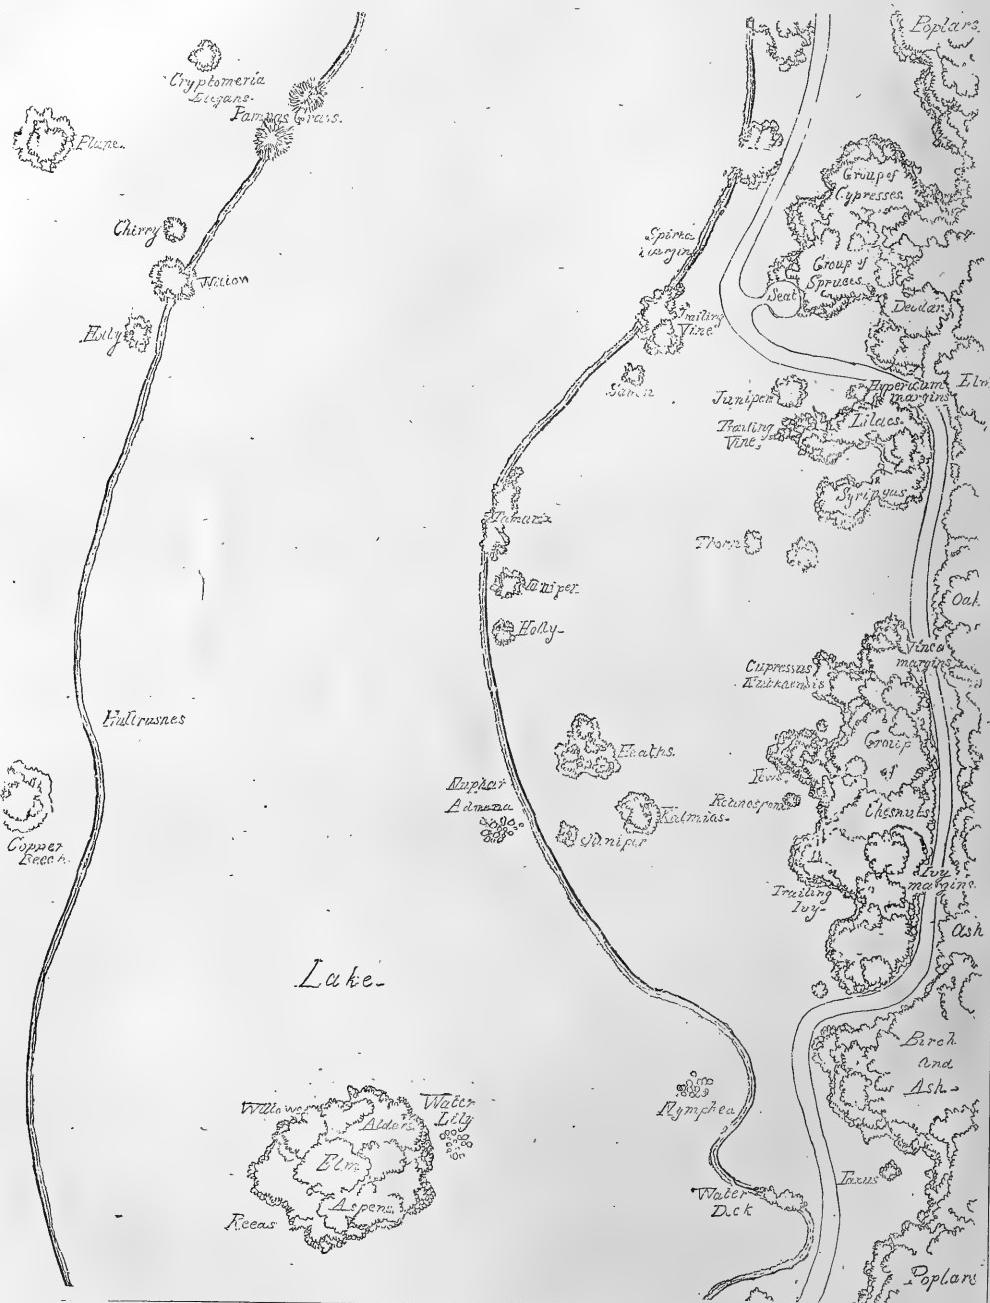

The Odour of Box.—So they walked over the crackling leaves in the garden, between the lines of box breathing its fragrance of eternity; for this is one of the odours which carry us out of time into the abysses of the unbeginning past; if we ever lived on another ball of stone than this, it must be that there was box growing on it.—*Elsie Fenner.*

THE PLANTING AND LAKE MARGIN AT BERRY HILL.

We this week engrave a plan of a portion of the pleasure-grounds at Berry Hill, to show the beautiful character of the planting carried out there by Mr. Marnock. The comparatively small portion represented enables us to show the planting much more clearly. Besides, this small portion of good work clearly shown and clearly understood will teach much more than a large plan, in which the eye is caught by walks, drives, and other details which, while they make a plan seem pleasing to some, are only fraught with danger to garden scenery. Here we are brought face to face with a graceful piece of water and a narrow slip of ground running between it and the public road, and we can study its treatment without having the eye of the tasteless offended or that of the injudicious beguiled by the geometrical twirlings which are unfortunately rarely absent from garden plans or gardens, but which have nothing to do with pure gardening. Our plan gives a clear idea of the planting, and also of the free and tasteful disposition of the margins of the water, but only a visit can give an idea of the charming effects of the scene from many points of view.

What are the merits of the planting, and the disposition of ground shown by the plan? 1st. The natural flow of the margins of the water. The true and natural way in which the banks slope into the water cannot be seen, but it helps to lend a great charm to the place. Two kinds of wretched water margins may be named in opposition to this: the railway bank-like margin, in which the ground rises stiffly and abruptly; and the French pseudo-natural style, in which the very edge, instead of being allowed to kiss the water, is plastered with a tarry compound, and made to look like a section from a newly-tarred ship's side, both in colour and curve. The kerb-stone style is nearly allied to this. The most violent example I know of it is in the public gardens at Boston, U.S.^c. The line of cement and stones that guard the edge of the ornamental water in the Regent's Park for the past few years is quite as bad in its way, as may be seen from the suspension bridge near Hanover Gate. 2nd. The tufts of water plants, and isolated specimens and groups near the margin, are well selected and placed. An isolated specimen of the common Tamarix is quite lovely by the edge of the water. Dovaston's Yew, too, near the margin, and on one side slightly drooping over it, is very effective. Groups of stately water plants, like the Lythrum, Epilobiums, and taller rushes, and of floating ones like the water lilies, are most effectively placed in various positions. 3rd. The formal lines which margin most of our ornamental plantations are unseen. Hence the most perfect ease. The scene is as free from stiff formalism as some quiet little lawn by the side of a mountain lakelet. 4th. There is a rich variety in the planting. No hasty glance suffices to exhaust its interest; no eye, however learned in plants, may not find a new friend or a fresh lesson. We have only been enabled to write the name of the family in many cases on the plan. The "group" is often a whole family of distinct species of our handsomest trees or shrubs. In some cases the ground beneath the trees looks much too bare; but in the smaller groups on the grass there is nothing in wild plant-life more lovely than the way the beds and groups of the various kinds of sainv and other dwarf conifers send their shoots fearlessly over the short grass, and the way the American and other vines throw their long shoots over the low, grassy banks. The grouping of the various families, too, is noticeable, as superior to the general mixture and dotting plan. 5th, and lastly for the present, the breadth of sweet little lawns preserved is the most noticeable feature of all. On the small lawn, fringed by tufts of Tamarix, trailing vine, and with the groups of heath and Kalmias, the effect would have been totally destroyed by dotting specimens. Now, from every point on it the varied planting towards the road is seen to the greatest advantage. Not less charming are the peeps through it and across the water to the open sweep of rising pasture-land on the opposite side. Some might suppose it needless to point out the advantage of this last feature. Not so! In the great majority of gardens, when a pretty new conifer arrives it is usually planted in some open green spot, and if the garden ever bore any evidence of thoughtful design, by perseverance

[JAN. 6, 1872.]

THE RIGHT PATH.—PLAN, SHOWING A PORTION OF THE LAKE AND PLANTING AT BERRY HILL, TAPLOW.

in this direction it is soon obliterated. Mr. Marnock, who designed Berry Hill, tells me he frequently finds, after an absence of a few years, all his openings and bits of verdant foreground planted over with young conifers as regularly as a cabbage plot.

CONDUCTOR.

THE IN-DOOR GARDEN.

BLECHNUM BRASILIENSE.

(SYN., CORCOVADENSE.)

For mixing with such palms as Latania, Phoenix, Chamaerops, and others, this is a fine plant, with much majesty of port; while the undulating margin of the pinnae add to its charms of a minor character. It is a plant of free growth, and sufficiently hardy to be grown in the open air in summer. Though not generally termed a tree fern, it is, nevertheless, a good dwarf one; excellent for decorating greenhouses, in which it relieves the monotony produced by masses of fuchsias, pelargoniums, and similar plants. Its spores vegetate freely, and if put on a damp wall, in any unsightly corner, they will grow into nice-sized plants. Those who wish to have tropical effects with little trouble should, by all means, have this fern, which is not only a plant of very great beauty, but one which will grow and appear dressy at all seasons of the year.

J. CROUCHER.

THE IN-DOOR GARDEN
FOR JANUARY.

By THOMAS BAINES, SOUTGATE.

Stove.—Calculate what the probable requirements for the next few months will be as regards cut flowers and blooming plants for general decoration, and provide accordingly. A blaze of bloom in the flower-garden in the dog-days would be but a poor recompence for the absence of the more simple—yet, nevertheless, more welcome—harbingers of spring; and if this holds good in out-door gardening, it is equally applicable to that carried on in-doors. Therefore, look well as to what it may be necessary to introduce to the cool end of the stove, forcing-pits, or whatever structure is available for bringing on such plants as are required for bloom later in the season. At no time of year are roses unacceptable, and at no season are they more valued than in early spring. To have them early, the best way is not to prune them in autumn; but, to place them in very gentle heat with all their summer growth on them; keep them as near the glass as possible. But be careful not to admit cold currents of air upon them, otherwise mildew is certain to attack them. Feed them well with liquid manure, but not in too strong a state. When flowering is over, give them a season of rest in a cold house or pit, and then prune them, surface dress with strong loam well enriched with rotten dung, and re-pot in similar material such as require that attention. When the frosts are over, plunge them out of doors for the summer, where they will make their growth, attending well to them with water. Plants so treated will last good for at least a score of years. I should recommend the stock employed for this purpose to consist of half Teas and of half hybrid perennials. Towards the end of the month, cut back, and pot a portion of the Allamandas, Clerodendrons and Bougainvillaea glabra, the last being the only species of that handsome genus suitable for pot culture. If this plant is well managed, it is almost a continuous bloomer, and it is a universal favourite, its delicate mauve bracts harmonizing well with every form and colour of flower with which I have seen it associated; and if not grown in too hot a place, it will last, in a cut state, for a week at a time. A portion of the Glinoxias and Achimenes may also now be potted, and they should be placed in heat as soon as the operation is performed; for if left in the potting-shed in cold damp soil even for a few days, they are in danger of rotting. Re-pot the

different kinds of Alocasias, using half sphagnum well chopped and half fibrous peat, with a liberal admixture of sand, for the purpose. Richardia (Calla) ethiopica grows well, and if placed now in moderate heat, will soon throw up its great white, trumpet-shaped flowers. Spring-struck Hydrangeas will likewise succeed in a similar temperature with the Richardia, and at no season will they be found of greater service than in early spring. They are much more useful grown as small plants with single heads than in a larger state; they last long in bloom, and admit of being set about with impunity in places where many plants would suffer or die outright. Eucharis amazonica is another useful plant, and a general favourite. It will throw up its flowers at any time, after having been subjected to a slight check before being introduced to heat. This is a plant that may be grown to almost an unlimited size, or it may be divided, and kept in eight or ten-inch pots. These smaller-sized plants will be found the most useful for general purposes, and especially for winter and early spring blooming. Some of the older plants of Fuchsia should now be placed in heat. A light kind named Mrs. Marshall is one of the best for general decoration, blooming, as it does, early, in the greatest profusion. As soon as the plants have "broken," they should be shaken out, and re-potted in three-fifths good loam, one-fifth rotten dung, and one-fifth sharp sand, the whole made firm in the pots. But, in potting these and all other plants, do not fall into the common error of filling the pots too full, to the exclusion of room for sufficient water at one application to moisten the whole of the ball; for, if only the upper portion of the soil and roots get moistened, the result is almost sure to be disease, and sometimes even death.

Orchids.—The plants in the East-India house will now be at rest, and with their growth fully matured, are in the best possible condition for a thorough cleaning, with a view to remove all scale, thrips, &c., which, with the low temperature now maintained, will not increase fast, and, consequently are much easier to reduce to a minimum than when circumstances are more favourable to their development. Those who are not disposed to grow a collection of orchids, but who, nevertheless, value orchid flowers in the winter season, should not omit to grow those most valuable winter-blooming favourites, Calanthe vestita, C. Veitchii, Dendrobium moniliforme, Zygopetalum crinitum, Lycaste Skinneri, and Cyprideum insigne. These are comparatively cheap, of easy culture, and produce a profusion of flowers that last long, either on the plant, or when cut. See that all potting materials, such as sphagnum, fibrous peat, and clean crocks, are in readiness for that operation when necessary.

If any of the Cattleyas, or other inmates of the Mexican house, show, by excessive shrivelling of their pseudobulbs, that they are getting too dry, apply water; but let it be done sparingly, otherwise it will excite growth, which is most undesirable at present. The roots of many of these plants are pushing actively at this season, when they are otherwise at rest. See, therefore, that these do not become a prey to cockroaches, woodlice, and other pests, that are particularly fond of them.

Conservatory.—Where Pelargoniums have not yet been placed in their blooming-pots, no time should be lost in doing so. For compost, use good loam, with a moderate admixture of thoroughly rotten dung, and sufficient sand. Do not use too large pots—eight-inch ones are sufficient for the largest plants—and pot them hard, otherwise they are disposed to produce more leaves than flowers; keep them as near the glass as possible in a night temperature of 45°, and water them sparingly for the next two months. The best time to pot Lilies is in the autumn, as soon as they die down; they dislike any mutilation of their roots, which are then less active than at any other season. If not already potted, however, that ought to be at once attended to. They thrive well in rich, fibrous leach, with a little leaf soil and some rotten dung added, with enough sharp sand to insure porosity. Great differences occur in regard to the time of blooming of Lilium auratum. If a dozen bulbs of it are started,

Blechnum brasiliense.

Dwarf tender Tree Fern: suitable for shady dels during the summer months.

some may not flower for two months after the others, the consequence of which is a desirable succession. If plants of *L. lancifolium* are not required to flower until autumn, when they are most useful, they should be placed in as cool a temperature as possible, to insure the exclusion of frost, and all the kinds used for pot culture should receive just sufficient water to keep the mould in a healthy state, but not more until they appear above the soil, and then they should receive all the light and air possible to keep them short and compact. Now is a good time to divide and re-pot *Vallota purpurea*, which is a most useful autumn bloomer; but be careful in the operation not to mutilate the roots more than is necessary. It will be found to succeed in soil similar to that recommended for lilies. Remove all blooming plants from the conservatory as soon as their flowers become shabby or unsightly, and give prominence to such fine foliaged plants as do not require a higher temperature than is maintained here. Many of the *Agaves*, *Yuccas*, *Dasyliatrons*, &c., though not furnished with gay flowers, possess attractions for those who can appreciate the beauty of form quite equal to the most gorgeous blooming plants. All work that can be done at this season should be completed as soon as possible; for unless time is taken by the forelock, it is difficult to recover lost ground.

NOTES AND QUESTIONS ON THE IN-DOOR GARDEN.

Anthurium magnificum and **Alocasia metallica**.—Will *A. magnificum* thrive under the treatment which Mr. Baines recommends for *A. Schererianum*? I have also a plant of *Alocasia*, in a twenty-inch pot, measuring five feet in diameter. I do not wish to increase the size of the pot: how shall I proceed?—*Ed. Woollen, Charlton.*—Mr. Baines, to whom your query has been submitted, says that *Anthurium magnificum* and *Alocasia metallica* will both succeed perfectly in the soil recommended for *A. Schererianum*. Both, he adds, require liberal pot room, and in repotting only remove by hand any soil that may be getting sour. Give to both plenty of drainage, and supply them well with weak liquid manure during the time of active growth. They also require a somewhat higher temperature both while growing and of rest than *Anthurium Schererianum*—say a night temperature of 60° with a rise of 5° in the daytime, when at rest; when growing, 70° at night, and from 80° to 85° by day.]

Bouvardia Davidsonii.—This variety of *Bouvardia*, which is of American origin, appears to be a sport from *B. Hogarthii*, which it resembles in every particular, except that the flowers are white instead of red, and, I think, a trifle shorter in the tube, which will be an advantage to them in cut state. A few small plants which I had of it are covered with flower-buds; I therefore conclude it will be a free-flowering plant, and valuable for furnishing flowers for coat bouquets. *Bouvardias* of all kinds are extremely useful, as they flower all the year round, and are plants of easy culture.—*W. Howard, Balham.*

Acacia Riehana (humifusa).—In reference to the *Acacia* noticed at p. 73 as *A. humifusa*, allow me to remark that it was under that name here, or something like that name; but feeling dissatisfied about it, I sent a piece of it to Dr. Hooker, and he gave it the true name, *A. Riehana*—under which it is now known, and figured in the *Botanical Magazine* last year. It is, as you justly observed, a most elegant and admirable plant for a conservatory or elsewhere. What enhances its value so much is, that it is not only beautiful when in flower in April and May, but that it is graceful in appearance all the year round, and at this season more particularly, when plants of a graceful, persistent character are so much valued. I have used it with satisfaction in every conceivable way, from the decoration of an “ancestral portrait” to the adornment of the human head, and in “button-hole” bouquets. It will stand days without water, as you may prove by the piece I send you per post; so that it is needless to say how admirably suitable it is for the dinner-table, twined, as it may be, to any degree among candelabra and the like, without injury in the least. How such an elegant plant has been overlooked so long, I cannot imagine. It has been kindly distributed through me by the Marquis of Beaumont to many of our principal gardens, Kew included, where, no doubt, in years hence it will form a feature, as it is here at present. On the whole, *Acacias* have no beauty but when in flower. This, however, is a grand exception to the rule, the beauty of which cannot be known but by seeing it in its improved state as it now is in the garden here.—*H. K., Floors.*—[The singularly graceful shoot sent seems after its voyage in the cold and ten days' existence in London as fresh as when cut.]

Carbolic Acid Plant.—*Andromeda Leschenaultii*, which grows in the Neilgherry Hills, has been found to yield carbolic acid. Mr. Broome, the medical officer for that part of India reports that it is far superior in purity to the ordinary product of coal tar, being less deliquescent and free from any admixture of noxious comitants; as its cost is far above that of the mineral product, and as latter can be chemically purified, the discovery has no economical commercial value; but it is nevertheless interesting in a botanical point of view.—*Daily Paper.*

CEMETERIES.

EVERY considerable town requires, or will require at no late day, not only fields for the disport of its living swarms, but other fields (requiring exceptional care of their own) for the interment of its throng of dead. Indeed, the living can steal some chance moments of rural enjoyment, by bursting into fields and gardens of their neighbours, or by plunging into untamed wilds; but a man cannot steal a grave: there is no larceny possible to us of some charming spot upon a neighbour's hill-side where our bones may rest

In dealing with the question of a public cemetery adequate to the needs of a growing population—as in the question of a public park—our larger towns show a provoking delay, blinding themselves year after year to the necessities of the case, and deferring positive action, until the needed investment assumes gigantic proportions. There are scores of towns whose grave-yards are absolutely brimming with the dead, who yet take no decisive measures for an increase of the privilege we all sigh for at last—of a quiet sleep under trees.

Among the requisites for a country cemetery are to be named, I think, first, a distance not exceeding forty minutes drive from town; next, a friable soil, and one not underlaid with rocks. An absolutely dry soil is also desirable, and a sheltered position: for in the last tender offices of respect to the dead, we are exposed to all seasons, and a harsh sweep of northerly winds adds dismaly to the chill of a wintry burial. I think we love to catch, too, in such localities, the first warm beat of spring sunshine, and that we welcome the early violets on graves we know, as we welcome them nowhere else.

If with all these requirements can be associated picturesque variety of surface, secluded glens and pools, where, as in Mount Auburn, water flowers show their white regalia, it would be well; but there should be no sacrifice of the quiet seclusion which should belong to such a spot to compass the garish charms of over-nice and pretentious gardening.

Park gardening and decoration is one thing; that of cemeteries is quite another. Aims, treatment, effects, all should be different. Sombre masses of wood, heavy shadows, these should be present; above all things, there should be avoidance of those sudden surprises and graceful deceits by which gardeners sometimes win their lesser honours. Great simplicity of design is also essential, not only as in keeping with the sepulchral offices of such ground, but being, to a certain extent, proof against the harm which an elaborate plan must suffer by injudicious planting in private inclosures.

From the fact last named—the giving over of individual lots to private caprices of planting or arrangement, non consummate or finished gardening can, of course, ever be looked for in our cemeteries. The general effect will be at best spotty, and lack coherence. The course of the principal drives or walks, the establishment of the capital masses of foliage, the ordering and adaptation of the encircling belt, the finish and appointments of the entrance-way—these are the objects which will demand taste and skill for their happy execution. To twirl a great labyrinth of serpentine paths through a forest, shaven clean of its under-brush—to throw rustic bridges over a flow of sluggish ditch-water, and to construct grottoes where they sit like mountebanks in the hollows of the hills, is not good gardening for cemeteries—if it be good anywhere. If there be great reach of irregular surface, there should be sunny glades to contrast with masses of solemn shade. Rustic or other littlenesses should not pique and arrest attention. The story of the place should be told in the largest letters of the gardener's vocabulary and the interpretation easy—quiet—seclusion—rest.

Something might be said of the character of the trees which should be planted in these fields of the dead. The willow is the traditional weeper, and in place; but such product of the gardener's art as a weeping ash is a terribly starched mourner, and should be banished as an impertinence. All curious and rare exotics, I should say, have no place there; unless, like the yew or the cypress, they bear some story of association which chimes evenly with the solemn shadows around. The darker evergreens generally are most fitting; and there is a variety of the Norway spruce, with long, pendulous arms, that is one of the stateliest and comeliest and friendliest of mourners it is possible to imagine. If the Mediterranean cypress would but

withstand the rigour of our season, its dark plumes, leading up on either side to the gateway of a tomb, would make a standing funereal hymn.

Near to Savannah, in Georgia, and upon one of the creeks making into the irregular shores thereabout, is a cemetery called, if I remember rightly, Buena Ventura. In old times, any visitor at the Pulaski used to find his way there, and was richly repaid for the visit. There was no proper "keeping" to the grounds. You passed in under a lumbering old gateway of unhewn timber; the paths were not carefully tended; there was much of rampant and almost indecorous undergrowth; the tombs were mossy, and the graves, many of them, sunken; but great live-oaks over-reached your path, and from their gnarled limbs hung swaying penants of the weird grey moss of the Southern swamp lands—festooned, tangled, streaming down—now fluttering in a light breeze, and again drooping, as if with the weight of woe to the very earth. There was something mysteriously solemn and grave-like in it. The gnarled oaks and the slowly swaying plumes of grey told the completest possible story of the place. Had there been no tombs there you would have said that it was the place of places where tombs should lie and the dead sleep. I have alluded to the scene only to show what and how much may be done by foliage and tree limbs, with their investing mosses, to give character to such a spot.

Neither the live oak nor the Spanish moss is available, indeed, in our Northern latitudes; but there are various degrees of fitness in the trees at command. The yew and the compact-headed Austrian pine, and the balsam fir always in their sables; even the much degraded Lombardy poplar, in full vigour, carries a ceremonious, self-possessed stiffness not unbefitting; while the glittering-leaved beech, and hornbeam, on the contrary, with their ceaseless, idle flutter, are the most unseemly of chatterboxes. The ash, again, without liveliness of colour has great dignity of carriage, and in its half mourning of autumn purple is one of the stateliest and fittest of attendants:

I know there is a philosophy which denies the propriety of seeking for, or multiplying, any solemn symbols, in connection with death, or the places where the dead lie; which believes in opening wide and laughing landscapes around graves, and in smothering all memory of the short-lived, funeral black under the gayest of colours. It seems to me, however, that so far as such a philosophy puts its meddlesome liveliness upon churchyards and tombs, it is only a gay hypocrisy. Death is always death; and the place where the dead lie always Golgotha. The real grief that goes thither with its bitterness, will be put down by no pelting of bright colours, and mock grief may be mended by what solemnity belongs to the scene.

—D. G. Mitchell.

THE FRUIT GARDEN.

THE FINEST PEARS FOR WIRE TRELLISES.

INQUIRIES having reached us as to the best kinds of pears for furnishing neat wire trellises now justly becoming popular, we have much pleasure in publishing the following list. They have been selected specially for this purpose by an experienced fruit-grower well acquainted with each variety, and the conditions which suit it best. It is most desirable to exercise caution in selecting pears for this purpose, as if bad kinds, or those that do not ripen properly, are selected, the result will be anything but satisfactory.

Those marked with an asterisk are especially recommended. No fixed time can be assigned for ripening, as much depends upon seasons, localities, condition of the trees, &c., and some pears, such as the Marie Louise will ripen in succession for two or three months together. The following kinds, however, ripen, as a rule, during the months under which they are arranged:

JULY, AUGUST, AND SEPTEMBER.

- * *Doyenne d'Eté*.—Small; excellent; a great bearer; requires to be gathered before it is quite ripe.
- Peach* or *Poire Pêche*.—Medium size; greenish yellow; slight musky flavour; excellent.
- * *Williams' Bon Chrétien*.—One of the finest of pears; large and, excellent; requires to be gathered before becoming yellow or the flavour is gone.
- * *Beurré de l'Assomption*.—An earlier, larger, and superior form of Williams' Bon Chrétien.

Souvenir du Congrès.—Another form of Williams' Bon Chrétien; very excellent.

Beurré Giffard.—Medium size; pyriform; excellent in quality; ripens early.

SEPTEMBER AND OCTOBER.

Beurré d'Amanlis.—Large; melting; of excellent quality and a great bearer.

Jersey Gratioli.—Large; russety, melting; an enormous cropper; and fine in quality.

* *Flemish Beauty*.—Large, russety, splendid quality, a great cropper, and sometimes very beautiful.

British Queen.—Above medium size; warmly russetted; fine melting flesh; excellent.

* *Beurré Superfin*.—Large, roundish, pale lemon-coloured, russet, fine, melting, buttery, hardy; a great bearer, and very excellent.

* *Louise Bonne de Jersey*.—One of the best pears in cultivation; a great cropper.

OCTOBER AND NOVEMBER.

* *Fondante d'Autunno*.—Medium size; roundish; fine; rich; melting; great cropper; hardy.

* *Suffolk Thorn*.—Medium size, warmly russetted, fine, melting, rich, a great cropper, and hardy.

* *Madame Treyre*.—Medium size; very rich; melting; juicy; excellent.

Comte de Lamay.—Medium size; roundish, rich, and sugary; great cropper; hardy.

Seckle.—Small, but very rich and excellent; a great cropper.

* *Thompson's*.—Medium size; rich, melting, and excellent.

* *Marie Louise*.—A well-known excellent pear, and one which cannot be too much cultivated.

* *Beurré Bosc*.—A very hardy and prolific sort, of excellent quality..

NOVEMBER AND DECEMBER.

* *Maréchal de la Cour*.—Large and most excellent; great cropper; hardy.

Beurré Clairgeau.—Large and very beautiful; moderate in quality; a great cropper; hardy.

* *Beurré Diel*.—Large, and in some situations most excellent in quality; a great cropper.

* *Clout Morceau*.—A large well-known pear of the highest quality.

Doyenne du Comice.—Large; probably the finest pear in cultivation; invariable good; moderate cropper.

DECEMBER AND JANUARY.

* *Winter Nelis*.—Medium size; melting, rich, and excellent; a moderate bearer.

Beurré Sterckmans.—Large, melting, rich, and vinous; a great cropper.

* *Ne plus Meuris*.—Medium size, good quality, very hardy, and a great cropper.

Zéphirin Grégoire.—Medium size, rich, sugary, and vinous.

* *Beurré Rance*.—Large, and in some situations excellent.

* *Josephine de Malines*.—Medium size; rich and excellent.

The Shiraz Apricot.—This does not differ much in appearance of tree from the better known varieties; it is indeed very much like the peach apricot, and like that it is very vigorous. It is, however, very different as regards its fruit, which is distinct from that of all the varieties of apricots known to our gardens. It is distinguished by its elongated form, and principally by its kernel, which is elliptical, pointed at the two ends, resembling that of certain plums. Another distinctive character is its flesh, which has nothing in common with that of any other kind. Instead of being dry, more or less clammy, with little sugar, and of a somewhat acrid flavour, like the flesh of apricots, it is soft, pulpy and honey-like. This apricot is without doubt the best of all; it is delicious; its flesh is so melting that it has not much consistence of texture, and therefore it softens quickly after being ripe. When better known, it cannot fail to be preferred to all other kinds for dessert. The fruit has nothing about it to flatter the eye, and owing to its want of consistence it is not likely to be a good variety for commercial purposes; but it is probable that it will make excellent preserves. It must not be confounded with another which was much spoken of some years ago, and which was said to have come from Smyrna, and to have sweet kernels, which after all was not surprising, as this character is common to many varieties of apricots. The leaves of this kind are smaller than those of the apricot of Shiraz, and its appearance generally resembles that of the kind called Musch Musch. We received the Shiraz apricot from M. Regel, of St. Petersburg. The

following is an enumeration of its principal characters; Tree vigorous, in form and aspect very near the common apricot, which its flowers also resemble; fruit longish, heart shaped, slightly narrowed at the base, then suddenly enlarging, and gradually narrowing to the apex, which finishes in an obtuse point; skin pale yellow, or white-yellowish, frequently splitting; flesh yellowish and tender, very melting, soon soft, and almost pulpy, sugary and honey-like; water abundant, lightly and agreeably perfumed; kernel quite elliptical, attenuated in a point at both ends, filling completely the cavity.—*E. A. Carrière (in Revue Horticole).*

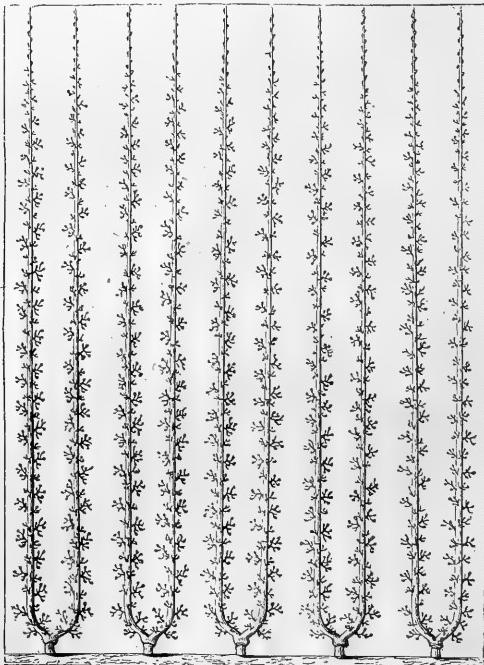

THE UPRIGHT SYSTEM OF TRAINING FRUIT-TREES ON WALLS AND ESPALIERS.

The value of this system is not sufficiently known with us, yet there is no country in which it is certain to be of such great use. Wall culture is necessary for the production of the finest fruit in many northern and temperate climes. We seem to have long recognised this fact, but not to a sufficient extent, and the progress with wall-fruit cultivation is very slow. Not in one garden out of ten is sufficient attention paid to it, while it is most rare to find the walls of gardens in

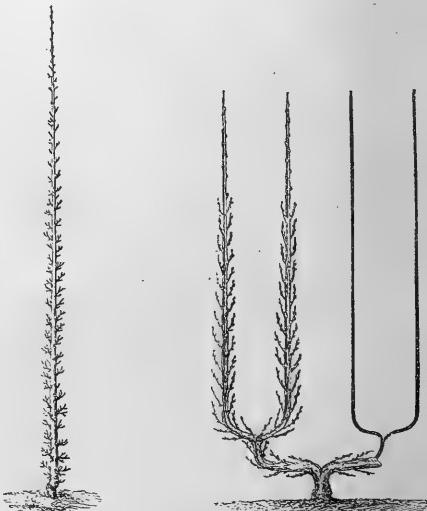

formed some new varieties will have come to light, and the judicious cultivator will be anxious to clear away the results of so many years' work.

There is no need to spend even one-third of this time in the covering of even the highest garden walls with forms of trees as fruitful, as agreeable to the eye, as any of the old large forms, and much more easily made. The simplest and best form for every kind of wall-fruit is the erect one, with from one to four or five branches ascending from the bottom to the top of the wall. In this way a good cultivator, by selecting healthy and vigorous plants to begin with, may furnish a wall ten feet high in two years from the time of planting.

To do so, he would not, of course, follow the common practice of cutting hard back the shoots; if he thought they would not break regularly, he would bend them down to induce them to do so. With good young trees, three years are the most that should be required by any gardener to cover the wall by this system. It must not be supposed that it is applicable only to the pear; it is equally so to every other kind of fruit-tree worthy of a place against a wall. In the case of the peach a still smaller form is, we are quite certain, desirable. A peach-tree with two branches like a capital U may seem awkward to persons only accustomed to the fan mode of training; but we have seen many walls perfectly covered by it on the Continent, and it is far better suited to our climate than a larger form. Trees trained in these particular forms are not required to begin with; we have simply to take, in the case of

Upright Pear-trees in the U Form.

Single Upright Pear (a good Form for very High Walls).

Peach-tree in the double U Form
(Sketched after Spring Pruning).

the pear or the apple, a young nursery tree, with its five branches or so, and train four or five of them, as may be required, in a vertical manner against a wall, and at equal distances.

The general adoption of this system would soon fill our fruit-rooms and cover our half-naked walls. It would prove of the greatest possible advantage to gardeners generally, in enabling them to rapidly cover the many bare walls one sees; and if a desirable system for ordinary garden-walls, it is much more so for the walls of stables, houses, &c., which it takes years to furnish by the common plan. The only case where it is not so suitable as a spreading mode is on very low walls and trellises. These, however, should never be erected for fruit-growing purposes.

Examples of walls as well covered as those shown in our

which considerable pains are taken with the fruit-trees covered as they ought to be. We will assume that the cultivator is sufficiently aware of the importance of walls in the production of the very finest fruit, and that he has selected the varieties really worthy of culture in this way. After these there is a third condition of success indispensable to perfect wall culture, the absence of which leaves half our wall-surface bare and robs us of quantities of the finest fruit. This is the true mode of covering walls quickly and well—the erect training. The wrong and the tedious, and therefore the profitless mode, is the large fan or horizontal tree, which takes a dozen years to form well even in good hands, and perhaps by the time it is

woodcuts are not unfrequent in France and Belgium. When in the neighbourhood of Geneva in 1868, the late Mr. H. A. Watson, then gardener to Sir Robert Peel, showed us many examples of walls well covered with peach and other trees trained in this form, and we have lately seen a very good example of growing the apple thus with Mr. Sage, in the garden at Ashridge Park, who covered a portion of his walls in two years with choice desert apple-trees. In THE GARDEN for December 9th figures of upright forms admirably suited for tall wire trellises were given.

NOTES AND QUESTIONS ON THE FRUIT-GARDEN.

Make Your Trees Branch Low.—Train your pear trees so that they will branch at a distance of one or two feet from the ground. The advantages are easily enumerated.

1. They are easy to trim.
2. It is easy to gather the fruit.
3. Falling fruit is little injured.
4. All branches being sturdy will not be strained by over-bearing or over-weight of fruit.
5. The soil will be kept shaded and moist.
6. The trunk will be protected from the scorching sun.—*Horticulturist.*

Wiring Fruit Walls.—Mr. Fish merits the best thanks of young gardeners for his sympathetic observations under the head of “Pruning and Nailing in the Cold.” He says truly that there is a great amount of tying and nailing to be got through in a certain time, but if gardeners would advise their employers to adopt the French system of wiring walls, they would save much labour and inconvenience. The antiquated system of decorating the limbs of fine young trees with rags ought now to be classed among things of the past. When the plan of wiring was brought into notice my employer had all the walls in the kitchen-garden fresh pointed with mortar, first fastening the fruit-trees, many of which are large and old, and, after having the guiding-nails inserted, had the wire put behind the trees, drawn through the eyes, and made fast at each end of the wall. The raidisseur or tightener I placed about midway on each wire, instead of at each end. Two of our walls, with south aspects, are each eighty yards in length, and one raidisseur was found to be sufficient for wires that length. The result is admirable; the trees look better and bear better than under the old plan, and there is a great saving of labour. The wiring was done in 1869, so we have had time enough to prove its utility. Our crops of wall-fruit during these two last years have been good. Our walls required upwards of 3,000 yards of galvanised wire.—J. M. H., *Ledbury*.

THE FRUIT-GARDEN FOR JANUARY.

BY WILLIAM TILLERY, WELBECK.

Out-Door Fruit.—January being in general one of the severest of the winter months, the planting of hardy fruits during the next few weeks must be ruled by the state of the weather. If mild, this operation may still be performed; for even winter planting, if the roots are mulched, is better than driving it off till the spring. If pruning has been neglected in November and December, it should now be attended to. The nailing of wall-trees should likewise be vigorously carried on in mild, dry weather; for this work, if neglected in the autumn and winter months, often sadly interferes with pressing operations in the spring. Figs on walls, if not protected, should now be so, as severe frosts in January and February often injure them.

Orchard-House Fruit.—Having grown in pots or in the borders in an orchard-house many of the newer varieties of peaches, nectarines, apricots, plums, and cherries, last year, the following list of the sorts, and their time of ripening, may not be without interest:—Of peaches, the earliest kinds grown in pots here were the Early Beatrice, Louise, and Rivers, all three varieties ripening in July in succession. The Early Beatrice ripened on a wall in the open air on the 20th of July; but its flavour was watery, and not so good as the fruit grown on the pot trees. Hales' Early York is a delicious small peach, like the Early York; but it ripened earlier in August than that variety. Dagmar, another of Rivers's seedling peaches, ripened about the middle of August, and is a high-coloured and good-flavoured kind. Malta, a small peach of the Noblesse section, was the juiciest and best flavoured of all the August sorts. Magdala, another new kind ripened in the end of August. It is creamy in colour, with a crimson cheek, and is well flavoured. Of the newer varieties of September peaches, the Alexandra Noblesse, Dr. Hogg, and Stump the World, were the best. Some were grown in pots, and some were planted out on the back wall. The latest sorts, ripening in October and

November, were Lord Palmerston and Princess of Wales, the latter a very large creamy-coloured sort, slightly tinged with rose next the sun, and a great acquisition amongst the latest varieties. Among nectarines, the earliest in ripening was Lord Napier, which was fit for table about the beginning of August, the same season as Hunt's Tawny. The Stanwick and Pine-Apple ripened about the end of August, and were two very high-flavoured varieties. The Victoria was the latest in ripening, and is a valuable sort for late keeping and flavour. Of plums, the newer kinds grown in pots were all of the gage section. Oulin's Golden Gage was an early sort, ripening in July. McLaughlin's Gage is an excellent American variety, which ripened early in August. Boddaert's Green Gage was a very good large plum, ripening in the middle of August. Transparent Gage was one of the very best flavoured of all the gages, and was ripe in the beginning of September. Among cherries, the earliest in ripening in May was the Guigno Tres Precoce, and about the same time the Belle d'Orléans. The Frogmore Early Bigarreau, and Early Lyons, were ripe about the end of May; and the Bedford Prolific about the middle of June. Of apricots, Precoce Doulins was a very early and good kind, ripening in July. Grosse Pêche is a variety as large as the Moorpark, but was earlier in ripening. St. Ambrose, a French sort, does well in pots, being better flavoured than when grown on the walls.

Early Vines.—Those started in December will now be breaking, and they should have air on all favourable opportunities; but the giving air to vines during severe frosts in January and February requires much attention, especially if the weather is windy. A temperature of 60° during the night, and a rise to 75° in the day, when the vines are in bloom, will keep all safe. Vines lately pruned will want the rough bark peeled off them, and they should be dressed with some strong composition, to keep mildew and insects in check. I have always found the following mixture very efficient for the purpose, namely, four ounces of soft soap, six ounces of sulphur to a gallon of water, and as much quicklime and clay as will bring the mixture to the consistency of thick paint. The water must be boiled, so as to melt the soap; the other ingredients should be stirred in, and the mixture used when cold. When it is used for peach or nectarine trees, more water and clay must be added to cool it; for I have known the young bark and flower-buds of these trees injured by it when it is put on too strong. Home-made brushes of bast matting, tied on short pieces of stick, are quite good enough for painting the mixture on the trees, and, to make safe, every cleft must be filled up; and when the first coat is dried, a second application must be made on places missed in the first dressing. If the vineeries are heated by pipes with troughs in them, all the sulphur and lime of last year's dressing should be scraped or washed off, for fear of rusting the tender berries after the vines are out of bloom. When the vines are forced early, the outside side border should be protected by some slightly fermenting materials, such as litter, or tree-leaves; and if covered on the top with wooden shutters, the covering will not want renewing till taken off in the spring.

The earliest forced peaches will now be in bloom, and the night temperature may rise from 50° to 55°. Peach-trees swelling their buds in the second peach-house will require daily syringing, and the atmosphere of the house should be kept damp by sprinkling the floors and pipes.

Pine Apples.—For the general stock maintain a mean temperature of about 60° at night, allowing an advance of some five or more degrees during the day.

Cherries.—When cherries are forced early, the temperature must be kept low, never allowing it to rise above 50° until the fruit is set.

Strawberries.—A second batch will now want introducing to the shelves of a peach-house or pit at work. For early forcing, plants with good plump crowns ought to be selected; and I find those potted in rather small pots with good matted roots always set their fruit the best.

Cucumber House or Pit.—At this dull time, cucumber plants are frequently much infested by thrips, so that repeated fumigations must be resorted to, as well as syringings, to keep down red spider. A sowing of both cucumber and melon seed ought to be made early in the month, to raise plants to fill up vacancies. I find early melons do very well in boxes in a pine stove, selecting Scarlet Gem and Egyptian Green Flesh as the types of the high flavour of early sorts.

When French beans are forced in stores or early vineeries, they must not be placed too near other plants, for fear of introducing red spider. I find the best soil for growing them in is good strong or turkey loam; and the varieties most to be depended on forcing early are the Newington Wonder and Fulmer's. Forcing for the spring supply.

THE FLOWER-GARDEN.

OPUNTIA RAFFINESQUIANA.

ALLOW me to add the testimony of my experience as to the complete hardiness of this Opuntia in this climate. I got a plant of it in the spring of 1869 from Messrs. Haage & Schmidt, of Erfurt, which has ever since that time been in an open border exposed to all weathers. Last winter was particularly severe; and this winter the thermometer, quite near the plant, has marked 21° below zero centigrade. It was often covered with a foot in depth of snow last winter, and it has been so once this year (1871) already.

This Opuntia is a very free bloomer, and its dwarf-branching habit makes it better suited for out-of-door vase or rock-work culture than for a border. All the Nopalea division of Opuntia are very rapid growers. Many of them have fine flowers, and bloom freely; but they shortly get very large and cumbersome. I practised at one time the following plan of keeping a large collection in a comparatively small space. I chose some large specimens of stout, erect kinds, such as Tuna, pseudo-Tuna, coccinellifera, &c., and grafted a branch (frond) of a different kind on almost every branch. This was very easily effected, by cutting the end of the branch to be grafted into a sharp wedge at its lower extremity, inserting it into a gash made on the branch of the stock, and running one of the Tuna's sharp spines through both of these, to maintain the graft in its place.

To show what a large size some of the Nopalea will attain even in this cold climate with very little artificial heat, I may mention that, some years since, I saw in an old tumble-down conservatory some miles from here a plant of the Tuna, or pseudo-Tuna, that had been originally grown in a wooden case, but from which the bottom had long since rotted away, leaving the roots to ramble at pleasure in the earthen flooring. This plant had reached the roof, fully twenty feet high, and had already forced out several panes of glass. Its diameter fully equalled its height, and it formed a thick mass of fronds borne on stout stalks, or rather, trunk, as thick as a man's leg. The rusty old stove, shaky sashes, and broken panes, fully bore testimony as to the plant getting but little artificial heat. I saw it in midsummer, when it was really a grand sight, covered with thousands of sulphur-coloured blossoms, as large almost as half-crown pieces.

Versailles.

FREDK. PALMER.

THE FOXGLOVE.

ONE of the most beautiful features about some of the French woods, especially in those connected with many of the old royal residences, is the masses of gorgeous-coloured foxgloves in all their natural beauty, associated with bracken and heather. One spot particularly calls for especial notice in the Versailles wood, through which the Chemin de Fer de l'Ouest passes to Rambouillet and on to Brest. This spot, I venture to say, is unequalled anywhere for such masses of this splendid, uncultivated flower. There may be places in this country where foxgloves look and thrive as well, and, no doubt, there are hundreds of places where they would grow and flower in perfection were a few hundred plants planted in favourable spots at first, since it would perpetuate itself easily. This was done at one or two private places, to my knowledge, and was brought about by the sight of those above mentioned. I could mention a few places in France where the proprietors introduced them with effect near the flower-gardens, in large masses, alongside the avenues that in all French chateaux run away right and left into the uncared-for woods. Foxgloves among masses of green, whether bracken or what not, have a grand and majestic look, such as is not easily forgotten when once seen; and I think, in places where we too often see such masses of nettles, with a very small amount of trouble we might see in their stead the beautiful foxgloves, as a rule, in perfection.

I purpose planting some hundreds next year about, here and there, among rhododendrons—newly planted rhododendrons, for where these thrive in the natural soil I have invariably seen the foxglove do well. Many hundreds of plants can be raised from a good packet of seed, and, nowadays, when we have such fine, spotted, improved strains, I think we may look forward to the time when all our woods, and shaded, frequented nooks, will be beautified with this fine wild flower. To those who have had no experience with this plant I would further remark—procure a packet of seed and sow

it in a pan, in a moist heat, in February. As soon as large enough to handle, prick out an inch apart or so in a frame or under a hand-light where there is a slight heat, and where no frost can enter. A month or so after they will be large enough to plant out into borders, to be lifted again in autumn to plan in permanent places anywhere and everywhere where suitable, to flower the following summer. They must be nearly two years old, and strong, ere they flower profusely. We had spikes of flowers last year fully four feet long, from two-year-old plants. These were planted, however, in garden soil among large rhododendrons; and had a fine effect. They continued to throw up spikes all the summer, and being a moist year, they, moreover, being situated on an east aspect, shaded by a high wall, they continued to flower till September.

I can't say they are as brilliant as the gladioli, but one thing in their favour is, they can be grown among large evergreens in a dressed and formal way as well as in the shady woods. At the Chateau de Dampierre, the residence of the young Duc de Luynes—who was killed during the late war, under melancholy circumstances—about twenty miles from Versailles, I remember seeing, some years ago, on its being pointed out to me by M. Cide (the gardener there) an improved spotted form of foxglove. It was amongst a lot, growing wild; and he kindly gave me a pod or two of seed, from which I have grown the sort here and elsewhere. It is among foxgloves what the new spotted form of gloxinia that came out at the French Exhibition in 1867 is among gloxinias, and it varies in colour from pure white to dark pink and purple. The one I speak of as growing in the Versailles wood is a much darker variety, and shows at a distance, but is not spotted, as is the sort which I grow.—H. K., in "Gardeners' Chronicle."

CHRISTMAS HORTICULTURE IN VIENNA.

In no part of Europe is there found so near an approach to the glory of the autumnal tints of the American forests as in the eastern provinces of Austria, especially in the neighbourhood of Vienna. A press correspondent writes as follows of the Austrian foliage in autumn, and of the foliage which succeeds it at Christmas, "about the glorious grandeur of the timber in the Prater, and the wonderful tints with which autumn decorated the giants and dwarfs of that forest." Indeed, they were beautiful at that date he had reason to know, but now, in the last days of the expiring year, we have an arboricultural phenomenon which puts them quite in the shade. "Within the last few hours a very large plantation of trees and a nursery-garden of shrubs have broken out not only into leaf, but into bloom. The colours of the leaves, fruit, and flowers bring to the mind the fruit and vegetable market at Lisbon. The crops are so great that, after Christmas, and indeed before the 6th of January, they must be very much thinned, or the trees will be useless till next year. This sort of fruit harvest is an annual institution in Vienna. The produce is gathered by young children, who are not paid any wages, but get their share of the gathering. With so much lemonade and cake each *par noctem*, the workers work 'short time,' and are home by ten. A great amount of women's labour is, however, lost at this harvest, as the mothers or aunts usually sit on benches while their young charges bear all the heat of the evening. It is evident that this class in Austria take great pride in their children, and in their's and their own costume. Many of the mothers would look well in a London ball-room, and the children be 'much admired' as bridesmaids at a grand wedding. Sometimes when the trees are stripped—and it is wonderful with what rapidity this horticultural operation is executed—the employers give a supper, consisting chiefly of sweet-stuff, to their youthful gang, who then go back to their lodgings—usually very clean and well-kept—in charge of their parents. The trees stripped are an improvement on the Christmas rose, which, according to authorities, produces 'beautiful, white flowers about Christmas.' White flowers! *allez donc!*, these produce red, green, yellow, black, blue, pink, fruit and flowers—and will be known to those great botanists and night horticulturists in England, Professors Gunter, Fortnum, Mason, Hedges, Butler, &c., as the arbor-mulier or Christmas Tree."

The Viennese cultivators of Christmas trees exceed those of all other parts of Germany in taste and ingenuity. Not merely are whole groves of young firs made to put forth luxuriant blossoms with an air of naturalness quite sufficient to deceive juvenile-botanists, who devoutly believe the inflorescence to be real—but artificial shrubs, such as camellias, paoniuas; palms in full bearing of real coco-nuts, are so beautifully executed that botanists of a larger growth might be deceived without being ashamed, so perfect is the deception. Vienna is the Paris of Germany. It has specialties in matters of taste as distinctive as the celebrated *articles de Paris*, and which fully equal them in elegance; while in matters of real horticulture, the art is nowhere carried to greater perfection in the matter of

real flowers for the table, at all seasons of the year. At the Imperial Castle of Laxenburg there are vast gardens (under the immediate superintendence of Herr Rauch, a pupil of our ever-regretted John Claudius Loudon), where table flowers are regularly produced for the Court, where they are deemed indispensable all the year round—the winter violets of the large new variety being produced there in the depth of winter with a luxuriance of bloom and richness of perfume which I have not met with elsewhere.—H. N. H.

NOTES AND QUESTIONS ON THE FLOWER-GARDEN.

Soil for a Rock Garden.—I am about to construct a rock-garden, and should much appreciate your full information of the best kind of soil for it. There is plenty of peat not far distant, but the garden is on a sandy loam. E. L. H.

[For a great number of rock plants almost any kind of open soil will do; and in a free loam numbers of alpine plants delight. To have plenty of soil, and that so

arranges that the roots may descend deeply into it, and find an abundant supply

of moisture in it during the heats of summer, is of greater importance than the

kind of soil. For some of the Gentians, for Spigelia marylandica, Rhexia virginica, and dwarf ericaceous plants, some portions should have a silvery peat

soil, and others a loamy soil, and others a sandy soil.

Roses and Evergreen Climbers for a North Wall.—Will you or any of

your readers kindly give me the name of a good, free-flowering red rose, to

climb on a wall which has a northern aspect? Also the names of a few pretty

flowering evergreen creepers, to plant on a wall with the same exposure?—L.

Letter.—You can do well with plant Amelis, a fine Bourgaut rose,

flowering purple crimson, and the yellow rose, Alba plena. If you have

room enough, Splendens, Lauré Davout, and Ophiria. It is not so easy to get

"pretty flowering evergreen creepers" for a north wall, though you may get

some excellent deciduous things for that purpose. If your soil is warm and

light, the myrtle may do well against your wall, and the Laurustinus will be sur-

to do so, and though it is not a " creeper," yet it is quite as easily trained against

a wall as any such. We have seen it grow very high and look beautiful against a house in France. The camellia may also be grown against the house in the southern parts of England and Ireland, and we have seen beautiful blooms cut

from such in February.]

Japan Creeper (*Ampelopsis tricuspidata*).—I have often

gratified the dessert with the beautifully tinted foliage of the Gros Guillaume, Black Prince, and West's St. Peter's Vines; but none of these

after they begin to change colour last long, and it is pleasant to have so

goodly an acquisition as the *Ampelopsis tricuspidata*, than which for

purposes of dessert garniture nothing can be more beautiful. Nor have we

yet done with our new friend. I have often to cater leaves for ladies'

maids who take an interest in adorning their ladies' hair for the evenings.

The leaves of the old Cissus discolor and the red racemea of flower,

and leaves of Euphorbia Jacquinifolia used to be favourites; but now, with the

extra ammunition afforded by this new *Ampelopsis*, I have no fear of being

destitute as regards fine leaves for that purpose.—Wm. Miller, Combe

Abbey Gardens.

Giant Sunflower.—This much-neglected plant not only forms a

handsome contrast in the shrubbery, but its numerous seeds are much

relished in the poultry yard, being particularly beneficial to the birds

during the mounting season. The sunflowers I have grown this season

measure from 38 inches to 43 inches in circumference, their heights ranging

from 8 feet to 12 feet, the circumference of stem from 8 inches to 9 inches

at the thickest part, and the seeds which I counted from one head

amounted to 1,630. I sow the seed from the middle of March to the middle

of April; the plants should stand at least three feet apart. If flowers

as large as the heads already mentioned are desired, the side shoots should

be nipped off as soon as they make their appearance at the base of the

leaves, leaving only the terminal bud to flower. The sunflower is a greedy

feeder, and will consume large quantities of liquid manure, which should

be liberally supplied after the plants have attained the height of about a

foot. Watering with soft water overhead in dry weather will be found

very beneficial. Wherever the sunflower is sown, a handful of soot should

be scattered pretty thickly over the spot to repel the attacks of slugs, who

are very apt to eat the young plant off as soon as it appears.—Thomas S.

Jerrold.—[Mr. Jerrold has forwarded to us two heads of sunflower, the

larger being 39 inches in circumference. As the seeds are greatly relished

by pheasants, and possess high fattening properties, it might be advantage-

ously sown in some situations; but it requires very rich soil, and is an

impoverishing crop.—Ed. Field.]

Aquilegia formosa.—I observe that Mr. Ellacombe recommends this as one of the most desirable of the genus. I never myself yet

had the good fortune to obtain it true. I am inclined to think it

must be rare, even if it be at all in English gardens. But my chief

motive now is to warn amateurs that the *Aquilegia formosa* of

Fischer, referred to by Mr. Ellacombe, and is, in short, merely a

double variety of the common Columbine sprouting into many shades.

The true *A. formosa* is closely allied to *A. canadensis* and *A. truncata*

(*A. californica* of gardens), but is described as having stamens and

styles not protruding beyond the mouth of the flower. I observe,

with regret, a disposition in some quarters to hybridize the species

of this genus. There is so much tendency to vary in some of them,

that I think the aim of the cultivator should be to obtain, and

retain, each species as pure as possible; for I doubt if any hybrid

will ever exceed in beauty or interest the original type, or that, if

such could be produced, that they could easily be perpetuated.—

W. THOMPSON, Ipswich.

THE FLOWER GARDEN FOR JANUARY.

BY G. WESTLAND, WITLEY COURT.

By means of neatness and order endeavour to render all ornamental grounds as enjoyable as possible. Walks and grass must be frequently rolled when there is no frost, and no greater improvement could be undertaken than to make grass verges and lawns perfectly level. I do not mean like a billiard-table or croquet-ground, but where the ground naturally slopes the fall should be uniform and regular. Where verges are irregular it is easy to turn back the turf and to make the ground quite level, and then re-turf, beating quite firmly with iron rammers; but do not give the edges the final trimming until such time as the grass has taken root, and all danger from hard frost is over. Smoothness, I need scarcely remark, is one of the main constituents of beauty; therefore a lawn which is not perfectly eye-sweet can never please. Turn up vacant flower-beds to the ameliorating influence of frost, and renew the soil in such as may require that being done; turn gravel walks, surface dressing them with a coating of fresh gravel, and lay box edgings. Frequently examine half-hardy plants protected during severe weather, and endeavour to render their covering efficient by giving additional protection when necessary; also protect bulbs during severe frost. Plant and re-arrange towering deciduous shrubs, keeping in view ultimate effect; and so dispose of the stronger growing varieties as not to overgrow the more delicate kinds. Even hawthorns, beautiful and desirable though they are, frequently occupy the front rank of mixed shrubberies, when they would have been better placed further back, or set in groups; but all the stronger growing kinds are in better keeping as park ornaments. The best for dress grounds are the different varieties of *Cratagus oxyacantha*, as, for example, Paul's new double scarlet. This is a splendid variety that merits extensive cultivation. *C. o. multiplex*, the best double white, *C. o. punicea*, the finest single scarlet, and *C. o. rosa superba*, may be accepted as fair types of the kinds that will give most satisfaction. The double varieties just named are splendid subjects for pot culture. If not already done mulch all newly-planted trees with leaf-soil, dung, or spent tan; top-dress hollies, rhododendrons, and such plants as may require stimulating, with rotten manure and soil. Prune deciduous plants and climbers, and train such as may require it. Shake snow from evergreen trees and shrubs as soon as fallen, for if it is allowed to lodge heavily on the branches much damage may be done.

Tender roses must be efficiently protected, and mulch dwarf roses of every description. More particularly is this necessary with such varieties as are worked on the Manetti stock. In planting roses on this stock it is important to see that the place of union of the bud with the stock be underground. The great propensity of this Italian briar to produce suckers, together with its tenderness, is, in my opinion, an objection to its use. I give the preference to such roses as are grown on their own roots; these, when well established, give less trouble and produce the best results. The more delicate varieties should be budded on the briar stock, which is harder in constitution than the Manetti. And I would advise the inexperienced to plant the most vigorous growers. Prune climbing and hardy pillar roses. By pruning I do not, however, mean the whole to be clipped over with the shears; on the contrary, use discernment in the execution of this operation. Strong growing roses, such as the Boursault, require well thinning out, shortening the young wood but little. Prune the moss rose by cutting out the old wood and shortening back the young, pegging down the shoots on the beds which afford the best means of growing this rose.

Austrian roses should have all weakly wood cut clean out and the head thinned, but do not shorten the shoots at all. Provence roses may now be pruned, but the pruning of roses in general had better be deferred for some time to come.

Pits and Frames.—In such as are heated give no more fire heat than is absolutely necessary to expel frost, and give air early in the morning as the state of the atmosphere will admit. Towards the middle of the month the stock of bedding plants should be looked over; and soft wooded plants, of which there is a scarcity, should at once be placed in a growing temperature to produce cuttings for propagation. The heliotrope is well deserving of extended cultivation, and is very desirable in mixed arrangements. The finest varieties for bedding are *Étoile de Marseilles*—a star, indeed!—Surprise, and Jersey Beauty, the last very dwarf, and one of the best for bedding.

As regards geraniums in boxes and store pots, a portion of the variegated sorts may be placed in heat when cuttings are required, but I would warn the inexperienced not to be in undue haste, as the loss of a week or two is often more than regained by the superiority of the cuttings put in later. Water carefully but effectually, so as to thoroughly moisten the ball. Cold frames containing comparatively hardy plants, such as Gazanias, Centaureas, Echeverias, and Veronicas,

&c., must be attended to as regards covering when the weather is frosty; and to insure the glass being kept clean, mats should be employed next it, over which a sufficiency of fern or litter may be strewed to keep out frost; during the prevalence of severe frosts and snow there is no necessity to remove the covering, as it will stand for a month, if need be, in perfect safety; but in such a case insure them afterwards to light by degrees, so that the transition is not too rapid. For those who have not the advantage of a propagating-pit, and who have to depend on heating material, now is a good time to get dung and leaves together, and thoroughly mixed, so as to become of an uniform moisture. Take advantage of wet weather to make labels and procure stakes of various sizes; trim and tie them into bundles. Wash flower-pots and store them away for potting, and see that soils are procured in sufficient quantities, and in proper condition for potting.

YUCCAS.

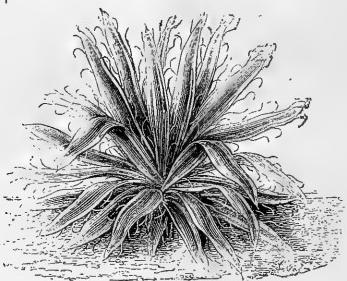

(Continued from p. 121.) ~

YUCCA ANGUSTIFOLIA.—A somewhat dwarf species, the whole when in flower not being more than two or three feet high. The leaves are thick, and rigid in texture, from fifteen inches to eighteen inches long, and about a quarter inch broad, of a pale sea-green colour, with numerous white filaments at the edges. The

Yucca filamentosa.

inflorescence is a simple raceme of white flowers slightly tinged with yellow. Till more plentiful, this had better be grown in warm borders, in well-drained sandy loam. N. America.

Yucca filamentosa variegata.

YUCCA CANALICULATA.—The leaves of this species are entire, i.e., neither toothed nor filamentous at the margin, and form a dense rosette on a stem which rises one or two feet above the ground. Each leaf is from twenty inches to twenty-four inches long, and two inches to two-and-a-quarter inches broad at the middle, very strong and rigid, and deeply concave on the face. The flowers are of a creamy white, in a large panicle four feet to five feet high. Fine for isolation or groups. Till more plentiful should be encouraged in favourable positions and on warm soils. Mexico.

YUCCA FILAMENTOSA.—A very common and well-known species, with a much-branched panicle, four feet to six feet high, and apple-green leaves, from fifteen inches to twenty inches long by one-and-a-half inch to two inches broad at the middle, fringed at the edges with grey filaments two or three inches long: the outer leaves spreading,

the central ones erect or slightly recurved. This species varies very much when raised from seed: one variety (*concava*) has short, strong, broad leaves, with the face more concave than in the type; another variety (*maxima*) has leaves nearly two feet long by two-and-a-half inches broad, with a panicle seven feet to eight feet in height. This species flowers with much vigour and beauty, and is well worth cultivating in every garden; not only in the flower-garden or pleasure-ground, but also on the rough rock-work, or any spot requiring a distinct type of hardy vegetation: and so is its fine though delicate variegated variety. All the varieties thrive best and flower most abundantly in peaty or fine sandy soil. N. America.

(To be continued.)

DOUBLE FLOWERS.

It will doubtless appear strange to some to be told that, botanically speaking, nearly all double flowers are imperfect, and that, so far from a double rose, for example, being more perfect than a single one, precisely the reverse is the case. But a little consideration will demonstrate the truth of this. A perfect flower may be defined as one which contains in itself all the requisites for the perpetuation of itself; it must therefore have at least one stamen and one pistil.

Before passing on to the consideration of the means by which double flowers are produced, and to the evidence of their imperfection, it is desirable that we should clearly understand what a double flower is. A great many of our most popular garden plants, of those which we most commonly term "double" asters, chrysanthemums, zinnias, marigolds, daisies, dahlias—have, in reality, no claim to that title.

We all of us know the common wild rose, with its calyx, corolla of five pink leaves, and numerous yellow stamens. If we contrast this with any of the double-flowered forms which are so justly esteemed as ornaments of our gardens, we shall be struck, not only with the presence of a great number of petals in the garden plant, but also with the corresponding absence of stamens. Here and there we may find a few stamens still remaining in the centre of the flower; but the blossoms in which they are found thus to remain are regarded as imperfect by the gardener, and are the exception rather than the rule. It is evident, therefore, that this development of the petals is co-existent with the diminution or disappearance of the stamens; and, as we have shown that it is on the presence of these stamens that the fertilisation of the flower depends, it necessarily follows that their diminution or disappearance must be accompanied by a relative diminution in the fertility of the flower. This transmutation of stamens into petals is the commonest method by which double flowers are produced.

Although it is only in cultivation that we find perfectly double flowers, there are many plants which, in a wild state, exhibit a tendency to become double. It is chiefly in such as have a great number of stamens that we notice this tendency; in the creeping buttercup, for instance, we usually find the normal number of petals increased, and perfectly double flowers of this, and of other species, are not very rare. The yellow bachelor's button of our gardens is but a form of the meadow buttercup in which all the stamens are converted into petals; and, as in consequence of this conversion the plant can never produce seeds, it is only by roots that this form can be propagated. Some plants, although but few, are normally semi-double, such as the camellia and white water lily; but in these species, although there are many rows of petals, the essential organs are not interfered with to any appreciable extent.

The majority of the double flowers which occur naturally, as well as most of those which are popularly cultivated, are composed of numerous separate petals (polypetalous), as amonoles, carnations, roses, stocks, wallflowers, geraniums; and, among monocotyledons, lycopers and tulips. In most of these cases—especially in such blossoms as have numerous stamens—the additional petals are chiefly derived from converted stamens, and this conversion is considered, as in the rose, essential to the horticultural perfection of the flower. Various other circumstances, however, in certain cases bring about the same result.

In monopetalous flowers—that is, those which have the corolla all in one piece, and not divided into petals—such as the primrose, we not unfrequently find the calyx assume a petaloid texture and appearance. This is often the case with double cowslips and polyanthus, which have thus two corollas, the stamens and pistil remaining unaltered. When the corolla is triple instead of double, we find the stamens converted into a corolla. Sometimes only one stamen is thus metamorphosed, and we then have a single petal protruding from the centre of the flower. Often, too, the mere increase in number of certain parts is the cause of doubling. In some cultivated double campanulas we find the monopetalous corolla split up into its component petals, and so becoming polypetalous.

It is interesting to notice the various artificial means which may be taken to produce double flowers. Suppose, for example, that out

of a thousand single stocks, one or two should be found with an extra petal—with five petals instead of four. By preserving the seed produced from one or two—by carefully raising, and again selecting only such plants as evinced the desired peculiarity—we might in time obtain specimens so perfectly double that in the attainment of our object we should have forgotten that we had at the same time effectually prevented the perpetuation of our treasures. This plan, however, of raising double flowers is far too uncertain, as well as too lengthy in detail, to be practically carried out. A French writer, M. Chaté, gives some interesting statements of the way in which double stocks are produced. "The gardeners of Erfurt," he says, "have for a long time, to a certain extent, monopolised the sale of seeds of these plants. To obtain these seeds the Erfurt gardeners cultivate the flowers in pots, and place them on shelves in large greenhouses, giving them only sufficient water to prevent them from dying. So cultivated the plants become weakened, the pods shortened, and the seeds less numerous and better ripened; and these seeds give from sixty to seventy per cent. of double flowers." M. Chaté's own method, however, is even more successful than this; he obtains eighty per cent. of double flowers, and that by very simple means. "At the time of flowering," he says, "I nip off some of the flowering branches, and leave only ten or twelve pods on the secondary branches, taking care to remove all the small weak branches which shoot at this time. I leave none but the principal and the secondary branches to bear the pods. All the sap is employed in nourishing the seeds thus borne." The result, as stated, is eighty per cent. of double flowers.

The passion for double flowers, now so general among us, seems to be an accompaniment of civilisation. Mr. Noel Humphreys thus speaks of their cultivation among the Chinese:—"The Chinese, having remained comparatively undisturbed for several thousands of years in the enjoyment of an advanced kind of oriental civilisation, in which a love of flowers has ever been a distinguished feature, succeeded in producing several kinds of double-flowering plants many centuries before such double-flowering varieties were known in Europe. Of these the double-flowering peach, plum, and cherry are now well

known. They were, indeed, pictorially known to us centuries ago by their representations in Japan ware and porcelain; but then our botanists only thought such representations imbecile vagaries of the Chinese pencil, and gave that ingenious people—those Celestials of the 'Flower' Empire—no credit for having positively produced by horticultural perseverance the flowers whose portraits they delighted to paint on their matchless China ware." Among ourselves, the rage for double flowers, which has resulted in the production of ugly double fuchsias and uglier double geraniums, appears to be developing. As an evidence of this, we may note that so common a plant as the double stock is mentioned neither by Turner nor Gerarde; but as, in 1629, both Johnson and Parkinson describe it, we may suppose that this improvement took place between the reigns of Elizabeth and Charles I. Double roses and pinks are of earlier mention; but many of our modern double favourites are of quite recent date.

In connection with this part of the subject it is worthy of remark that, in a natural state, double flowers are chiefly produced in the northern hemisphere, where the influence of cultivation is more extensively felt. Their distribution has been carefully traced by Dr. Seemann, who says that in Polynesia and the whole of Australasia not a single species with double flowers has turned up, although there are a few in South Africa and South America; the stamens of which are converted into petals. Since this statement appeared, however,

one exception—that of *Epacris impressa*—has been recorded for Australia. It is impossible to say whether the absence of double flowers from Polynesia and Australasia is owing to the non-existence of cultivators in those parts, or whether they really never occur. In Europe double flowers of various tribes are not unfrequently found wild. The fact that civilised man has always taken a peculiar fancy to them has caused their transfer to gardens and greenhouses whenever they are found. Hence the countries longest or most highly civilised have supplied the majority of double flowers—the camellia, most perfect of all, coming from China and Japan.

It is a curious fact that double flowers and variegated leaves rarely exist on the same plant; and those who regard the production of double flowers as an evidence of strength see in this a confirmation of their theory, variegated leaves being in many cases indicative of weakness. It has been asserted that they are never co-existent, but there are exceptions to the rule.—James Britten, F.L.S., in "Field."

BIRDS FOR THE GARDEN.

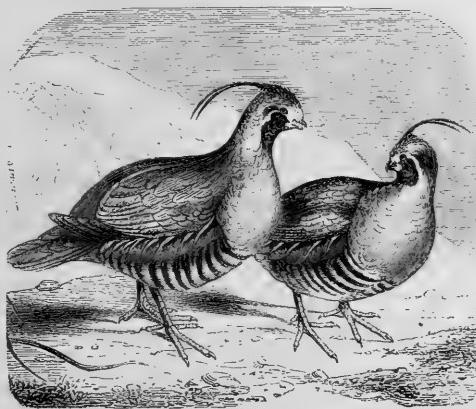

The Californian Quail.—Here and there on the rough dusty roads, in busy little groups, or escaping under the young pines and evergreens, this pretty bird is often seen in the lower parts of the sierras of California. And

happy is the hungry pedestrian who finds a dish of the fat and delicate bodies of California quail in the little hotel at the end of his day's journey, as I did at Grass Valley. The flavour is delicious, but the bird is so pretty with its long crests that one regretted to see the settlers' boys shooting them for their dinners, as they do the fat squirrels. For a country dating from 1849 (those who went there in that year are known as "old forty-niners") there are many interesting gardens in and near San Francisco, particularly in the suburbs of Oakland, on this side of San Francisco Bay. In visiting an unusually pretty one there, belonging to Mr. Moss, I was astonished to see my friends of foot-hills and highland valleys literally swarming under the acacias and other evergreen shrubs

of the garden. Mrs. Moss obtained some, and they had multiplied so fast that there were multitudes of them in the garden, in which they did not seem frightened in the least degree. I never saw a game bird, or indeed any bird, look so much at home in a garden before. Efforts more or less successful have been made to naturalise this as a game bird in England. Its beauty, harmlessness, and the fact that it is so much at home in a garden seem to point out the garden or pleasure-ground as the most desirable home for it. The bird is of a pleasing lead-colour, with an olive-brown gloss on the back and wings; the throat black, with a white line running backward from the eye; the crest black, and about an inch and a half long. Why should we not naturalise beautiful birds such as these in our pleasure-gardens?

W. R.

Dionaea muscipula.—Mr. Bain, late of the College Gardens, Dublin, a most successful grower of this plant, used to propagate it according to Mr. Balf's able secretary of the Royal Horticultural Society, Mr. Loddiges, as follows:—When the plant had got to the beginning of the year, he took up the plant, digested it of every particle of soil, and with very sharp scissors cut off the crown, which, when potted, formed a strong and perfect plant. He then took the remaining or basal portion of the axis, on the surface of which were the scales formed by the bases of the old leaves. This he cut into small transverse or other sections, so as to have a scale to each morsel. These he distributed evenly, as you would seeds, over the surface of a small pot, which he put standing in water, and placed uncovered on a shelf immediately under the glass, in an airy and perfectly cool house.

Californian Quail.

THE ARBORETUM.

TREES FOR TOWNS.

PLANTING requires to be done carefully everywhere. The *Arbutus* makes a glistening and beautiful bush for Ireland and the warm and genial parts of England and Scotland; but on the cold clay about London it is not worth planting. *Araucaria imbricata* is truly a noble tree in many parts of the country, notably at *Dropmore*, and at *Woodstock* in Ireland; and it is likely to make equally noble objects in many places where it has been more recently planted. But all that did not justify the "planter" who placed those noble specimens of it in front of *Tattersall's*, at Knightsbridge, there to perish of smut drapery and vile accumulation of London smoke and dirt. Planting trees in and near a large city requires as much judgment as anything I know of connected with arboriculture. It does not appear to be understood even by some landscape-gardeners; for I could enumerate several instances of extensive plantings in and round London within the past few years which have perished, from their total incapacity to withstand smut and the other "evil humours" of our London atmosphere.

At one time the vegetation of our gardens and shrubberies consisted to a great extent of trees that lose their leaves in winter. Then came the laurel, the Portugal laurel, the elegant tapering cypresses, and a host of evergreens from various parts of the world, and fashion wisely went in their favour immediately. This has been carried into London plantings, and with great detriment to vegetable beauty therein. Had half the attention and money that have been devoted to the putting evergreens to die therein been directed to the planting of ornamental, free-flowering, deciduous trees in the London squares and parks, we should by this time have an array of floral beauty in and about London in the early summer months which would put to shame the best of our summer parties. Deciduous flowering and ornamental trees should be the *sine qua non* of the London planter. When the fires are all alight in town, and smut darkens the very air, the leaves of the evergreens are fully developed, and reaping the disadvantages of it all. As a rule, they soon succumb; and what can be more miserable than a scrubby or a dying "evergreen"? The box, holly, *Aucuba* do, it is true, where the soil is free and light; but even these often fail, and look miserable to the last degree. But the deciduous tree is asleep when the deadly vapours are vomited so abundantly from our chimneys. All its life is wrapped up within it safe under a warm skin and a layer of mucilage, ready to burst forth into bloom and life of fresh young leaf when the fires begin to go out and the air of London to approach purity. Then it starts into flower and leaf; to go to rest again, as soon as people return to town and the fires begin to work with vigour. Deciduous trees do as well in and near London as they do in the country; whereas, in most cases, it is mere waste of money to plant evergreens or conifers.

The double cherry may be seen in flower even in London, fresh and beautiful as if in the open country. The charming pink, scarlet, and other hawthorns, do as well in and near town as in their own native woods; while, with the exception of the Japanese privet, there is scarcely an evergreen of which the same may be said. Now, as a rule, in the London squares and parks sufficient advantage is not taken of this fact; though *Victoria Park*, *Battersea*, and *Kensington Gardens*, contain fine examples of the kind of trees I allude to. If, instead of the miserable massing of starved privet and half-dying laurels, that never even acquire a respectable degree of greenness, and never yield a flower worth looking at, we had belts of those beautiful deciduous trees and shrubs to be enumerated presently, which burst into vivid green in spring and in early summer are covered with fragrant flowers of great beauty, how much we should gain thereby! The evergreen is planted for the sake of its refreshing colour in winter, but if our atmospheric conditions utterly prevent the attainment of this condition, why persist in throwing away money on such useless planting. Besides, our people do not—nor is it very desirable that they should—frequent our town parks, &c., during the depths of our cold, wet, and sunless winter. Therefore, the absence of vegetable beauty at that season is of slight

importance, although for my own part I prefer the winter aspects of deciduous trees to that of evergreens. Those noble old plane trees, marbled all over their stems, where the great patches of bark fall off, and betraying a mixture of picturesqueness and graceful symmetry which I know not where to find equalled among trees—the delicate grace of the Babylonian Willow, with its long swaying shoots stripped of their summer covering—the bright gleam of the yellow osier when the sun does shine on it through the almost ever-dark though shifting cloud canopy—these are things to be enjoyed even now in our London parks and squares; and this sort of beauty might be increased tenfold in and near London by the planting of the kinds of trees advocated. And, finally, a strong reason for planting such should be the beauty they afford when pushing into leaf in spring. There is no more beautiful, no more magical sight than the bursting into leaf of deciduous trees in northern and temperate climates. The beauty of evergreens does not equal it, because they lack that delightful changefulness. Change, perpetual change, is in some sort essential to our life and work; and, from an aesthetic point of view, the trees—bare but picturesque and perhaps noble or graceful in winter; "thrusting out their little hands into the ray" in spring; the most beautiful of all natural objects in summer, when a mass of fluttering leaflets green as an emerald; and full of mellowing and changeful beauty in autumn, when the leaves of not a few American trees that would do well near London assume tints of the most pleasing character—are far better for us than the evergreens, which we cannot grow in perfect health.

Of the trees best suited, then, for London planting, and which are likely to withstand the evil influences of its atmosphere, the following are the most prominent, and those which the writer has observed to flourish well under the influence of smoke, &c., and which, therefore, should be planted more extensively than other trees in planting our commons.

The great advantage of many of the things I recommend is, that they flower freely and beautifully. What can be more attractive than masses of the snowy *Mespilus* (*Amelanchier Botryum*) in April, or than the tiny rose-flowered almond trees, which grow well in the very heart of London with no attention after planting? Nothing more encouraging than to see these opening on a fine spring morning. They are not half sufficiently planted in our parks, and some of them indeed do not contain a specimen, the Regent's Park to wit, except we include a few young plants lately put in the new avenue gardens. But we want bold, natural-looking groups of these things instead of the ever-repeated limes, elms, &c. They are quite as cheap, and do even better than some of those common ones which, however desirable and indispensable, should not be the only trees to be observed in our recreation grounds, when we may buy some of the handsomest and noblest ornaments of the woods of America and Europe for a few pence a piece. The bird-cherry is also a free-flowering subject, especially suited for London. Then there is the weeping, double-blossomed cherry, which is certainly when in flower the most beautiful of all flowering trees, and yet it is very rarely planted, though nothing can do better than it does on the stiffest, coldest soil in the northern and north-western parts of London, simply because the leaves are off and the plant is at rest when the atmosphere is at its worst, and the leaves and flowers have time to come out and become fully matured and developed before the "blacks" of approaching winter come on.

Of course, everybody will recognise the value of the various kinds of horse-chestnut; and the plane is the noblest of all London trees. There are not a few of great merit which are yet too costly to be used for this purpose, and some few which are of such low stature and slow growth, that their planting would not be desirable, and, therefore, I omit them. The common lilac does so well, and flowers so freely, that the planting of its finer and variously-coloured varieties is very desirable. I allude to such as the Siberian, the white (*virginiana*), and, of course, the Persian, for the dwarf clumps. But space forbids individual comment upon each of the plants suitable for this work; and, therefore, I will give a concise list of the best deciduous kinds, and follow that with the names of a few of the best evergreens.—These are the Snowdrop-tree of which there is a good example at Sion

House; *Gymnocladus canadensis* (the Kentucky coffee-tree); a handsome tree; *Koelreuteria paniculata*, a handsome, graceful tree, with spikes of yellow flowers; the "Mock oranges" (various species of *Philadelphus*), which are covered with white flowers—fragrant, too; *Prunus sinensis flore pleno* and *triloba*, very beautiful shrubs peculiarly adapted for the margins of dwarfish groups in parts—not so well for common planting. *Sophora japonica* is a noble tree, with very graceful foliage, exceedingly well adapted for the poor sandy soils that occur rather extensively in some of our commons, in consequence of drought not affecting it. It can bear any amount of drought and heat likely to occur in this country without suffering in the least, and this surely is a great point! Not a few of the greater willows are very fine, and grow freely in London; and so does the *Alantus*, or Tree of Heaven, as it is called. It has great pinnate leaves, which, when looked down upon from the windows, appear like, and indeed are as graceful as, the fronds of large ferns.

The *Robinia*, or common *acacia* (Cobbett's Locust-tree), though a failure as regards the virtues which its advocate accorded it, is admirable for planting near, or rather in, cities, where it grows and flowers freely and beautifully. The common birch is not sufficiently used, although the most bewitchingly graceful of all indigenous trees. The weeping variety of the mountain-elm, or, in other words, the large-leaved weeping mountain-elm, forms a truly picturesque tree in winter, and affords dense shade during the summer months; the purple-leaved and virginalis also thrive freely amid the smoke of large towns. The Lombardy poplar is as valuable for its pointed habit, so to speak, as for its exceeding willingness to grow amid our smoke. It is surprising it is not used to better ends in our park planting. The Abolo poplar, too, is invaluable, and particularly its comparatively new white variety. But least of all must be forgotten the many noble American and European thorns, so full of flowers in spring and so full of bright fruit in autumn, freely attracting song-birds, the presence and the melody of which we should cultivate as far as possible.

Of the conifers, I doubt if any are worth recommending for London planting except the Scotch and Austrian pines, and these only pretty well out of London. The deciduous cypress (*Taxodium distichum*) might, however, be tried near the margins of the ornamental waters in our parks. The evergreens which do best are the *acubas*, *hollyes* (in great variety), box, yew, Japan privet (which flowers freely and sweetly, and is, altogether an admirable thing for London; it may be grown in a back-yard!), and the harder kinds of evergreen oak. Very few more, indeed, are worth planting. Bringing fresh, brightly-leaved evergreens and conifers to London, and there planting them, is generally as successful a practice as planting them in the salt sea would be. They either die, or become so miserable-looking, that it soon becomes imperative to dig them up and throw them away.—V. E. K.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Larch for Poor Lands.—My object in writing now is to give you particulars of a sale of larch just held on my father's property near Llanwrtyd Wells, in the Aeron Valley, in Breconshire. The trees are growing on sideland mountain land, barely worth five shillings an acre, and are two to three miles distant from a railway station, and nearly forty miles from any colliery. No. 1.—625 larch, growing on 3½ acres, realised £305. No. 2.—1,200 larch, growing on 5½ acres, realised £350. Thus 11½ acres of larch produced £1,250, or over £108 per acre. The trees had been planted by my grandfather, and were from forty to sixty years' growth. Had the plantation been situate either nearer the South Wales coal district or the midland counties, and, consequently, had the advantage of lower railway rates, a considerably higher price would have been obtained. The timber was very fine indeed: No. 3 averaged over 20 feet a tree, and several sticks contained nearly 60 feet of timber. The chief lots were purchased by a Manchester firm, and are to be sent to Stockport at a railway charge of over £1 per ton measurement. Great profit can be made by planting almost worthless land with larch.—John Lloyd, jun., in "Field."

Abies Menziesii.—In the arboretum at Bicton is a magnificent, perfectly-grown pyramidal plant of this conifer, measuring seventy foot in height, with a last year's leader, from two to three feet in length, at its summit. It is branched so densely, even down to the green sward, that it is impossible to get a sight of its boughs without pulling aside its branches or creeping underneath. Its boughs or trunk is nearly nine feet in circumference, the spread of its branches is upwards of forty feet in diameter. It grows freely, its thick foliage being of a lovely silver-colour underneath, and above rich vivid blue-green, and very distinct from that of every other conifer with which I am acquainted. Cones began to show themselves in April; they are of a delicate pale green, changing when nearly full grown to a rusty blue or greyish colour; when ripe they become a rusty brown. The seed ripens the end of September and beginning of October, and the cones soon open their scales on windy sunny days, and allow it to fly away and get distributed a long way off. The male catkins are pendulous, and very abundant in March and April, so plentiful indeed that I have seen on a windy, dry, sunny day the pollen wafting about in the atmosphere like a cloud of dust. By the time the cones, which are at first on the upper sides of the branches, are full grown the little branches on which they are produced have themselves generally made their growth; therefore the weight of the cones renders them pendulous, and a very splendid sight it is to behold so beautiful a shaped tree with silver-white-blueish shining green leaves and brown cones waving in the breeze; it is in short a sight when once seen not easily forgotten. Even at a long distance this tree shows to great advantage.—JAMES BARNES.

A Gigantic Tree.—In travelling from La Victoria, a small town in the province of Aragua, towards Puerto-Cabello, in Venezuela, the road leads, in part, along the northern shore of the Lake of Valencia, situated in a longitudinal valley nearly 1,500 feet above the level of the sea. This valley is of unsurpassed fertility, and Humboldt calls it one of the most charming realms he has ever seen in all his travels. In the middle of the road above mentioned, three miles west of Turmero, stands the famous Zamang, an enormous tree, belonging to the sub-order Casalpinoe. It is not so much on account of the height or the dimensions of the trunk for which this tree is celebrated; but it is the size, and especially the horizontal diameter of its head, that attracts attention. Its head is somewhat of the shape of an opened umbrella, and covers very nearly an acre of ground. In 1857 I measured the head in its greatest diameter from E.S.E. to W.N.W. most carefully, and found it to be 206 feet 11 inches. Fifty years preceding it was found by Humboldt to measure in its greatest diameter 192 feet, French measure, which is equal to about 204 feet 6 inches English. Hence we see that this extraordinary tree has, within fifty-seven years, increased the horizontal diameter of its head only by 23 feet, from which we may infer that it is of a good old age. The natives assert, moreover, that as far back as the discovery of the country by the Spaniards, three centuries and a half ago, the Zamang was, even at that early day, reputed for its enormous size. At the time I saw it, it was but thinly covered with leaves, and seemed to lack vigour of growth. The natives hold it in high veneration, and it was against the law to break even the smallest twig. Besides their own enormous weight, the branches sustain the additional weight of an astonishing mass of succulent heavy epiphytes and parasites, such as Bromeliads, Orchids, Cacti, Mistletoes, and fleshy Piperaceæ.—A. F.

UNDER THE VIOLETS.

Her hands are cold; her face is white;
No more her pulses come and go;
Her eyes are shut to life and light;—
Fold the white vesture, snow on snow,
And lay her where the violets blow.

And grey old trees of hugest limb
Shall wheel their circling shadows round
To make the scorching sunlight dim
That drinks the greenness from the ground,
And drop their dead leaves on her mound.

At last the rootlets of the trees
Shall find the prison where she lies,
And bear the buried dust they seize
In leaves and blossoms to the skies.
So may the soul that warmed it rise!

—Oliver Wendell Holmes.

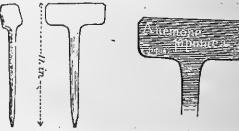

TREE, SHRUB, AND PLANT LABELS.

EVER since man first regaled himself upon fruits and green meat he has had some kind of plant nomenclature. But "the herb yielding seed and the fruit tree yielding fruit after his kind" were of comparatively easy division and remembrance, contrasted with our present host of plants, natives of every clime, and diversified so as to be almost beyond the comprehension of any but those who study botany in all its bearings. Although this science deals with the vegetation of the globe, and horticulture, strictly speaking, deals only with that useful or ornamental for our gardens, the stores of the latter have for many years become so rich and varied that a good system of naming plants has long been one of the chief wants of the gardening community. It is desirable even where the cultivator or proprietor may know every plant himself; and how much more so in the case of the great majority who have the ordinary degree of knowledge in this respect! It is desirable, too, from the aid it affords in helping young people to an initiatory knowledge and love for natural history. It is always satisfying to the mind to know the name of a thing, and if its native country be indicated and a hint given of its associations or uses, if it have any, a still better move will be made towards fixing it in the reader's mind; and when once a little knowledge is gained in this way it is always pleasant and usually comparatively easy to add to it. Anything which facilitates the acquirement of a knowledge of beautiful and interesting natural objects is valuable. A distinguished botanist once told us that he was first led to the study of the subject by the considerable amount of information and facts about plants placed so simply before the reader in some of Loudon's books on plant nomenclature. But books on botany, horticulture, or any other such subject are not usually referred to till they are wanted. On the velvety turf of lawn or garden is the most suitable place to make first impressions in this way, and, as nearly every pleasure-ground or garden has some permanent and interesting objects, it is most desirable that they should be named in the simplest and most useful way. For many years past the discovery of a really useful label has been a great object with our leading horticulturists. Yet it is very rarely that you see the plants well named, even in our best public gardens; and to find them so in a private garden is very rare indeed. Therefore it may not be unacceptable if we describe the best, neatest, and simplest system of labelling all kinds of plants—from the tiny greenhouse fern or rockwork alpine to the young towering Wellingtonia or rare old specimen of some old tree with a history.

It is a pleasing custom with many people nowadays to plant young trees, and of course they generally select something permanent and noble in character; thoroughly hardy it ought to be above all things, though subjects that perish during a severe winter are frequently selected. When they do well, these form grateful souvenirs or memorials of the planters; and really, considering how often our artists fail when they set about what Artemus Ward calls "sculpting" a memorial, a man of any taste would rather be commemorated by the least dignified of our trees than by many of the so-called successes, let alone the admitted failures, of the studio. Her Majesty, the late Prince Consort, and the other members of the royal family, have planted many trees in various parts of the country, as well as in their own grounds at Windsor, Osborne, and other places, and it is a desirable custom which many others practise more or less. In all such cases a good special and permanent label is desirable. It should be one to insert in the ground, neat and in every way presentable. Now, unquestionably the best for this purpose are those used in the Zoological Gardens in the Regent's Park, in a few cases at Kew, and in all cases, we believe in the royal pleasure-grounds. Round the mausoleum of the Prince Consort at Frogmore, for instance, the various members of the royal family have each planted a tapering and suitable young green pine, a family of trees in which the late Prince was much interested. These are named with the labels we refer to, the name printed, and then bedded firmly under glass in an iron frame, the whole closely cemented, and very neat. Not a desirable label by any means, observe, for a general collection, because expensive and permanent, but the best, so far as we know, for young trees of special interest. Now most people seek a permanent label for their plants; but we think it a bad plan, and for this reason: The contents of a garden are usually in a state of change; we are continually adding to and taking from them. New plants are introduced; and surpass the older kinds or new varieties, and then you "ring out the old" by throwing them away. A severe winter comes and kills a number of handsome pines or shrubs, which you determine not to plant again. Fashion changes the garden vegetation,

too, and then what becomes of the permanent labels that are cast and burnt into the face of hardware and cemented into cast-iron? They are generally useless, of course, and thrown aside with old iron, &c.

The label which can be used again is the best, and therefore we prefer a cast-iron label of what is usually called T shape, or, in other words, a slip of cast-iron with an oblong head slightly thrown back. These are cast very cheaply in the north, and will last for centuries. Of course you will have to paint and write the names of the trees on them when they come to hand; but that can be readily done by any handy painter, who will probably be glad of such a job in winter. In a large garden or a public garden where much naming is required, the right way is to train a boy or youth who is likely to remain in the place to do it; and we have done that in a few weeks by placing a

Cast-iron labels: the simplest, neatest, and best form for shrubs, herbaceous plants, and all cases in which the label has to be fixed in the ground.

copy of the desired kind of letters before him. We have found it of great advantage to give the face of the label a coat of copal varnish when the letters are dry, and we usually use white letters on a black ground, giving three coats of black over one of red-lead. These are the best labels for the usual shrub and choice young tree vegetation of a pleasure-ground or flower-garden. They will require repainting probably every half dozen years or so, and should you from any cause cease to cultivate the plants to which they belong, they may be newly painted and re-used at pleasure. One can get more than one hundred of them for the price of two or three of the permanent labels recommended for choice specimens. We suspect that with three coats of white lead, and the letters done in black, they would last longer than with the black ground.

Next we come to the wants of old trees, or any trees of respectable elevation and bough, or body, so to speak. When a rare tree attains size and dignity, like many of those at Sion House and in hundreds of fine old English parks and pleasure-grounds, it is still more desirable to label it than a young specimen, however choice. With such big trees it is always a mistake to use a ground label, which, indeed, we only recommend for the younger and choicer subjects, because another kind could not be affixed to the tree in a satisfactory way. The cheapest, best, and simplest of all labels for large specimens are made of pieces of tin about four and a half inches long by

Position for tree label.

Large and very unsuitable label used in Kensington Gardens and Hyde Park. (From a sketch in Kensington Gardens, 1870.)

three and a half deep. About half an inch of the upper edge should be bent down at a right angle so as to form a little coping for the label, two holes made just beneath the little angle, through which you pass a strongish copper wire, that is firmly nailed to the tree. Place it so that it may be easily read, and at about five and a half or six feet from the ground. This label will last for a long time, and is in every way satisfactory. All labels inserted in the grass in pleasure-grounds are liable to be pulled up by mowers, or some person or other, and in this way frequently get lost, whereas the labels on the bough are removed from all such mishaps, and are more satisfactory than any other kind whatever.

(To be continued.)

Weeds in Louisiana.—A Louisiana railway engineer was acquitted of neglect in running over a man, because "the weeds on the track grew so high as to obscure the person."

Gaultheria Shallon for Pheasant Coverts.—I wish to ask a question or two about Gaultheria Shallon, and its adaptability as food and covert for pheasants. Will it thrive as well or better than the Berberis under trees? Will it bear berries when well shaded, and does it grow high enough for covert?—A. L.

THE PROPAGATOR.

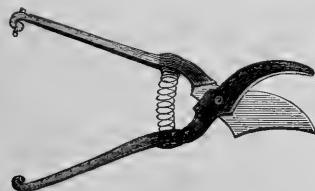

THE ART OF GRAFTING.

(Continued from p. 122.)

SEASON FOR GRAFTING.—On principle, grafting should be performed while the sap is in motion. When it is done in spring or in autumn, the time should be chosen when the sap has begun to flow, or before it has ceased to do so. In summer it is best to avoid the period of its greatest activity. In all kinds of grafting, the condition of the sap should be nearly similar in both scion and stock: when it is not so, it is much better to have the scion in a less advanced stage than the stock. The season of grafting in the open air is from the month of March till September, that is, generally speaking; in warm countries, vegetation commences a month sooner. Certain plants also preserve the flow of the sap up to October and November, which permits a delay in grafting them until that time. The time most suitable for the different methods of grafting will be indicated further on when we come to describe each method. The tradition which ascribes greater vigour to grafts made at the time of new moon, and greater productivity to those made at the end of the last quarter, we consider simply ridiculous. A calm atmosphere, and warm rather than rainy or cold, is both agreeable to the operator and conducive to the success of the operation. Heat, within certain limits, stimulates the nutritious fluid, while cold, on the contrary, chills and benumbs it. During the frosts of winter, grafting cannot be carried on except in the shelter of the propagating-house, where artificial heat and the other arrangements of the horticulturist will bring on vegetation to the desired extent at all seasons. Grafting under glass, either in houses or frames or under the cloche, is constantly practised from January to March, and from July to September.

IMPLEMENT AND APPLIANCES FOR GRAFTING.—Simple, handy tools, with well-steamed blades, and kept in good condition, are preferable to complicated implements with several blades or bristling with salient or cutting points, which may wound both the tree and the operator. The tool with a fixed blade is more firm in the handle, but one with a closing blade is more easily carried in the pocket, the apron, the tool-case, or the basket.

THE SECATEUR.—This is an implement formed with two arms of steel or iron, one of which terminates in a cutting blade, the other in a blunt bevelled crescent, against which the branch

The Secateur.

to be cut rests. The handles being wide and roughened on the back are, in consequence, easier to hold and less fatiguing to the hands. The secateur is used for the following purposes:—

1. For cutting off the heads of stocks which are too thick for the pruning-knife, and not thick enough to require the saw, in those modes of grafting which demand a preliminary shortening of the stocks.
2. For cutting off scions from the parent-tree.
3. After grafting, for cutting, above the scion, any stocks that have not been previously shortened, with the object of stimulating the development of the graft.
4. For cutting off the heels of grafts made on the branches of the stock after a year's growth.
5. For severing from the parent tree scions grafted by approach.
6. For pruning spine-bearing plants and trees.

In general, the wounds occasioned by the secateur require to be dressed with the pruning-kine.—“L'art de Grefier,” by Charles Basset.

(To be continued.)

THE KITCHEN-GARDEN FOR JANUARY.

BY JAMES BARNES, LATE OF BICTON.

If frosty weather should happen to set in, take care to have all salad and other kinds of vegetables required for use protected, and a store of such as are daily wanted should be put into cellars so as to be readily comestable. Maintain everywhere neatness and order; trench all vacant ground, turning it up in as rough a state as possible, so as to permit frost to pulverize and sweeten it, and to clear it of the larva of insects, which dislike exposure to hard frost. In trenching, open a thoroughly good trench, and break up the ground well at the bottom of it with strong forks, allowing it to remain rough and loose. Turn into the trench all surface vegetation and rubbish, and over that lay the mould from the next trench, again well breaking up the bottom; and so proceed till all has been turned over. By well moving the soil and getting down deeper and deeper every year, any depth of soil may be secured, and thus not only will crops be supplied with abundant food, but also, in dry seasons, with moisture. I was always an advocate for thorough drainage, deep culture, and surface stirring, and it is wonderful what luxuriant crops I have thus been enabled to obtain from land at first by no means good. Whatever vegetable refuse may be lying about, or collected at the rubbish heap, keep close together covered with earth and salted—salt being a good desodoriser. If there is one thing more than another a gardener should feel an antipathy to it is a weed; not only do weeds impair the appearance of a garden, but their production costs a considerable amount of money, inasmuch as they rob the soil of that which should go to support profitable crops. Deep trenching is a good way of keeping them in check, and there is no doubt that by deep culture the amount of most kinds of crops might be greatly increased. Surface stirrings should also be constantly carried out on all suitable occasions. Where required look out for a new stock of bean and pea sticks, and get them prepared so as to be ready for use when wanted. Seed lists, too, should be made out, in order to give the seedsmen time to get the goods put up in proper order before the busy season has arrived, and when you have the seeds home place them with the list methodically into thoroughly clean drawers or cupboards. See also that they are placed secured from the ravages of mice, and in a dry situation to prevent mildew or dampness. Of course, all kinds of vegetables, salads, &c., now in season, will be securely protected, and easily comestable daily, as required for use. Asparagus, seakale, rhubarb, and chicory roots should be all protected, in readiness to take up in succession at any time; no matter what the weather may be, these must be had for table, and if other vegetation is frozen in and covered with snow, there will be more inquiry for such articles. Cucumbers should now be sown pretty freely in succession, and those bearing fruit must not be checked for lack of heat, which should be 70° to 72° by night, and more by day, the increase being regulated by the light and sunshine we get. Sow early melons, which should consist of early, short-jointed, not over free vine and foliage-producing kinds. About the middle of the month will do. Sow in an intermediate house or frame in pans or boxes just free from frost, a pinch of some early variety of cabbage, cauliflower, or celery, to grow on in frames, to succeed the out-door stock when exhausted. For celery, like parsley and onions, there is an everyday demand. Carrots and radishes sow in succession, both on a slight bottom heat and on an open dry border if free from frost; look sharp after damping, shrinking, canker, mildew, and slugs. All young stocks of vegetables, salads, &c., dredge with wood ashes for mildew, and dry dust to prevent canker, &c. Keep everything clear of decayed leaves; surface-sir soil on fine days among growing crops; air freely to maintain strength and sturdiness, and cover and protect enough to prevent injury from severe frost. Mushrooms will be in request, and a valuable article they are to have in abundance at this season; kindly moderate warmth and gentle humidity should be maintained; about from 55° to 60° will be a secure warmth for keeping beds in full production of useful mushrooms; never allow draught; if you do, check will follow. It is a good plan to work the material for succession beds always in the mushroom-hous during the dead of winter, a practice which produces by gentle fermentation just the natural, gentle ammonia-charged humidity in which the mushroom luxuriates.

Hard Soil in Gardens.—There is one point in the practice of farmers that seems to me in advance of that of horticulturists—that is, the degree of artificial compression given to the earth for various crops. Agriculturalists seem to expend as much labour in crushing or rolling the ground down as in breaking or raising it up, and this not merely to provide a smooth surface but a compact tilth. This is considered essential for most crops on the farm; the roots bite the earth better, and the stems grow more sturdy and erect. The importance of a hard seed bed for onions is generally recognised in gardens, but beyond this a good many cultivators go little or no further. I have long observed that broccoli,

cauliflowers, cabbages, grow better if the ground has been trodden or rolled firm previous to planting. Firm planting is also helpful to a good start. Especially has this been seen to be the case with autumn cabbages planted towards the end of September to stand the winter. Last summer I had a striking instance of the value of a hard root-run for savoys, Brussels sprouts, and broccoli of various sorts. It happened in this way: The greater portion of our strawberry crop was cut off by the May frost. Still a few blooms escaped here and there. I was consequently unwilling to trench them down till the juicy fruit from such was secured. So towards the end of June a row of winter stuff was planted with an iron-shod dibber between each row of strawberries. Our ground is a strong loam, so the plants were put in with difficulty. They started freely, and have grown stronger than any planted at the same time in ground prepared in the usual manner.—D. T. F.

FLORISTS' FLOWERS.

BY R. DEAN, EALING.

AURICULAS.—Attention should still be directed to the removal of dead leaves, and to giving the plants plenty of air whenever the weather is favourable. We should, however, guard against heavy rains, strong drying winds, and severe frost. Water sparingly, but do not allow the plants to flag. During a mild January, root-growth will often become active towards the end of the month, and then extra water should be given.—Carnations and Picotees can scarcely be grown too hardy, provided they were early potted and are well rooted; but they will, nevertheless, require to be protected from cold icy winds, from rain, and from severe frost. Little or no water should be given, except in very dry weather, and then only in the morning, and at a time when there is no danger from frost. Avoid as much as possible wetting the foliage. Remove at once any decaying leaves, and see that the plants are kept thoroughly clean, and that they have full exposure at all times during favourable weather. If not already done, the soil required for the plants to bloom in should be at once prepared. If already mixed, it should be kept dry, and occasionally turned. It should consist of three parts good strong loam and one well-rotted manure; and it is a rule with Carnation-growers to prepare, in autumn, a sufficient quantity to last through the year. This should be well mixed together, laid in a heap where it can be fully exposed and frequently turned. As the surface becomes frozen in severe weather, the crust should be removed, so that as much of the soil as possible may be subjected to the influence of frost. The heap must be covered in wet weather. The loam should be carefully cleared of wire-worms; and, before using, a little coarse sand should be added to it.—Re-pot any Calceolarias or Cinerarias that may be getting root-bound, into larger pots, and keep them gently growing; place them near the glass, and give air on all favourable occasions, fumigating when necessary.—From Dahlias remove any mould or decay that may be found on the stems or tubers.—Hollyhocks, strong and healthy, should have abundance of air during fair weather. Keep them free from excessive moisture and from decayed foliage. Late-struck cuttings will be found to winter best in a greenhouse or pit, near the glass, where they can have the advantage of a little fire-heat in damp or frosty weather.—Pansies in beds may have a little light material, such as hay or fern, laid among them during severe weather; after frost, the plants should be gently pressed into the soil, from which they may have got to some extent uprooted; and the surface of the beds should be kept stirred when the weather is dry. From Pansies in pots, wintered in cold frames, remove the lights during favourable weather, but the plants should be protected from cold winds, rain, and frost. Dust with sulphur the foliage of any that may become affected with mildew, and remove decaying leaves.—Pinks in beds should be pruned with fern, or small branches of Spruce Fir, on the north and north-east sides. In suitable weather clear away all dead leaves from them, and place a little fresh soil around their stems, at the same time pressing the plants firmly down to prevent their being uplifted by frost.—Verbenas in pits or greenhouses should be looked over, and have all decaying leaves and harbingers of damp removed. If green-fly appears on any of the plants, they should be fumigated; every insect should, if possible, be destroyed.

The Manchineel of South America.—This plant, which is euphorbiaceous, is reported by the natives to be so deleterious as to give off poisonous effects to those who rest under its shadow. This has been denied on good authority, and was recently put to the test by the well-known botanist, H. Karsten. He gathered some of the juice of the tree in the district of La Guayra, and was presently seized with a burning feeling all over his body, followed by swelling, especially of the face and eyes. Next day he could not open his eyes, and their irritation continued for several days. On the third day he was able to do so, and the third day the swelling began to abate, and the cuticle to desquamate, after which he gradually recovered. These effects are similar to those produced by other Euphorbias; but the manchineel (*Hippomane manzanilla*) seems to differ from most in being capable of affecting individuals at some distance. Probably the immediate cause of the irritation is the dried juice, pulverised, and carried by the air.

Zethionema grandiflorum.—Among the various pretty tribes of rock crucifers, there is no family more valuable than the Zethionemas. They are remarkable for peculiar neatness of habit and delicacy of bloom, produced in dense masses when the plants are well grown. We have had long in cultivation some attractive species, and the above-named one is a very charming addition to the number. It is of larger and more sturdy habit than the excellent *Z. saxatile*, less spreading and prostrate in habit, less glaucous in tone, and with much larger flowers, purplish rose, in elongated spikes. It is a valuable plant for the rock-garden, thriving freely in sandy loam, and being exceedingly well suited for edges and slightly-elevated rocky banks. As a border plant it will also thrive where the soil is free and well drained. Being somewhat impatient of transplantation, it is desirable to allow some plants to ripen seed on sunny edges or borders. Seedlings in pots will, of course, transplant easily. It deserves a place in every collection of alpine and herbaceous plants.

Park Baths.—The important question of bathing in our public parks seems at present to be attracting some attention. Amongst the statistical facts of the past year, says the *Telygraph*, we are told that during its course no fewer than 433,000 persons bathed in the Serpentine. The statement is interesting from more than one point of view. Give the Londoner the chance of a plunge into cold water, or still better, of a swim, and you will find no reluctance on his part, to avail himself of it. The desire is as wide-spread as the means of gratifying it are, unfortunately, limited. Why should that be? As matters are conducted—or rather neglected—at present, the result is perfectly disgraceful to a city like London. Strongly as we desire that fresh clear water should be within the reach of every inhabitant of the town, we are not the less scandalized at such a sight as may be seen in Hyde Park every summer evening. It is not a right thing that hundreds of young men, in a state of nudity, should be seen running about the grass in view of the promenaders. Going up the Thames, above Richmond, it is impossible to take a party of ladies for an ordinary pleasure row without seeing every five minutes that it would have been a wiser course to leave them at home. The moral is, not that any real obstacle should be placed between the people and the fresh water, but that proper spots should be assigned for bathers, and that these spots should be carefully closed in from public view.

Dear Seed.—Some seed of *Primula japonica* was sold at Stevens's the other day, and realised the following prices:

	£ s. d.
½ ounce white flowered	12 15 0
" purple crimson	15 15 0
" white, with rosy centre	15 15 0
5-16th " scarlet	10 4 0
5-16th " lilac, crimson centre	9 5 0
3-16th " clear rose colour	6 2 0
½ " mixed colours	15 15 6

£85 11 6

1-16th of an ounce was said to contain about 8,000 seeds. The whole amount was 1-16th over 2½ ounces.—W. E. GUMBLETON, Junior Carlton Club.

COVENT GARDEN MARKET.—JANUARY 6.

Prices of Fruit.—Apples, per half sieve, 2s. to 5s.—Cobs, per 100 lbs., 70s. to 65s.—Filberts, per lb., 8d. to 10d.—Grapes, per lb., 2s. 6d. to 6s.—Lemons, per 100, 7s. to 10s.—Melons, each, 2s. to 5s.—Oranges, per 100, 6s. to 10s.—Pears, per dozen, 3s. to 6s.—Pine-apples, per lb., 4s. to 8s.—Pomegranates, each, 4d. to 8d.

Prices of Vegetables.—Artichokes, green, each, 6d. to 8d.—Asparagus, per 100, 8s. to 10s.—Beet, per dozen, 1s. to 2s.—Broccoli, purple, per bundle, 10d. to 1s. 3d.—Brussels Sprouts, per half sieve, 2s. to 3s.—Cabbages, per dozen, 10d. to 1s. 3d.—Capitaines, per 100, 1s. 6d. to 2s.—Carrots, per bunch, 5d. to 7d.—Cauliflower, per dozen, 2s. to 6s.—Celery, per bunch, 1s. to 2s.—Chillies, per 100, 1s. 6d. to 2s.—Cucumbers, each, 1s. to 2s.—French Beans, new, per 100, 3s. to 4s.—Herbs, per bunch, 2d. to 4d.—Horseradish, per bunch, 2s. to 5s.—Leeks, per bunch, 2d. to 4d.—Lettuces, per score, 1s. 6d. to 2s.—Mushrooms, per potte, 1s. to 2s. 6d.—Onions, per bunch, 4d. to 9d.—Parsley, per bunch, 2d. to 4d.—Radishes, per bunch, 2d.—Rhubarb, per bundle, 1s. 6d. to 2s.—Salsify, per bundle, 9d. to 1s. 3d.—Scorzonera, per bundle, 9d. to 1s. 3d.—Seakale, per punnet, 1s. 6d. to 2s. 6d.—Shallots, per lb., 8d.—Spinach, per bushel, 3s. to 4s.—Tomatoes, per sieve, 3d. to 6d.—Turnips, per bunch, 3d. to 6d.

Readers who may find it difficult to procure the numbers regularly through the newsagents or booksellers, may have them sent direct from the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance. THE GARDEN is sent to subscribers by Friday evening's post. All the numbers of THE GARDEN may be obtained from the office, and through all book-sellers and newsagents.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER.

"This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—Shakespeare.

THE FLOWER-GARDEN.

ROSES AND ROSE CULTURE.

BY S. REYNOLDS HOLE.

FOR another month, should the present open weather continue, rose trees may be advantageously planted. The best position is that in which they can enjoy the morning sun until the meridian, and in which, while they have abundance of air, they are protected by evergreen hedges, or other "breaks" and screens surrounding them at some little distance, from the full force of stormy winds. The best soil is a rich mellow loam, into which a walking-stick disappears to the handle, or a strong clay, with a slight element of lime, well dug, and drained, and dunged. If the purchaser wishes to grow the rose in its highest perfection, he must buy briars when he buys his rose trees, and bud the one from the other in the succeeding summer; because, as a rule, the first rose produced, if it escape frost and the buds around it are removed, will be the most beautiful. In some soils, and in some seasons, many of our best roses attain their full glory on the Manetti stock; but our indigenous Dog-rose is the most reliable parent of heroes. When the object is to grow roses for home enjoyment rather than for public competition, I recommend rose trees upon their own roots, or "worked" so low upon the Manetti or briar that the scion may be planted below the soil, and thus form additional roots of its own. I will add a most select list of roses which possess the three chief elements of excellence, (1) vigorous growth, (2) beautiful and (3) plentiful flowers.

Gloire de Dijon will supply more good roses in a season than any other variety, for it is first in spring and last in winter to produce its abundant flowers, exquisite in colour, form, and fragrance. It deserves a high wall, with a southern aspect, and there, upon its own roots, once fairly established, there seems to be no limit to its luxuriance and longevity.

As to *Maréchal Niel* there is no disagreement as to the glowing beauty of its golden flowers, but there has been much discussion as to its culture and constitution. The most successful method of treating this variety, without which no rose-garden is complete, is to bud it or graft it so low on the briar that it may be planted below the surface, and to give it a wall looking east or south. It is not frost-proof, but if the roots are well protected by manure placed upon the ground above them, three inches deep and a foot each way from the stem, applied in November dry and hard, no winter can kill the tree. However much an extraordinary frost may injure the upper growth, a grand reinforcement from below will come up in the following summer. And both these rose trees will grow admirably upon arches of wood or iron.

I dare not include in a list, which I intend to be very strictly limited to roses both robust and recherché, the lovely *Climbing Devonensis*. Budded on the Celine (hybrid Bourbon) stock, it makes upon a wall a marvellous growth, and gladdens sight and smell from May to December with its large, tea-scented blooms, but it has not strength to resist a cruel frost; and he who grows it must be prepared to mourn if an exceptional frigidity, as in 1860 and 1870, should chill the life-blood within. And yet I cannot refrain from saying, before I pass on to harder roses,—

"Tis better to have loved and lost,
Than never to have loved at all."

There is only one summer rose, by which is meant a rose blooming but once, which I must insist upon in a very choice

collection, and that is *Blairii* 2. There is no rose tree more generally useful. If its luxuriant shoots are only reduced one fourth of their length in pruning (the weakly wood being altogether excised), it produces its blushing beauties in abundance, amid foliage large and glossy.

From the Bourbons also I elect but one—*Souvenir de la Malmaison*. Grown upon its own roots, and well mulched through the winter, it gives us, early in summer and late in autumn, the flowers so exquisite in the eve of their full development. How well I remember the first healthy little plants which I bought at Berkhamstead a quarter of a century ago, some of which are in my garden now. Well might Mr. Lane say, as he looked fondly upon them, that "they were worth a crown apiece," for, long outliving the good rosarian who reared them, they have helped to win me many a golden prize.

Of Teas and Noisettes I have none to name, except the two first on my list, for these only are reliable as garden roses. Of the delicate loveliness of such flowers as *Devoniensis*, *Souvenir d'un Ami*, and *Madame Bravy*, no one is more cognizant than I, but, because they are *delicate*, I may not include them among varieties which are to be handsome and hardy also.

And so we come to those hybrid perpetuals, which combine both these good qualities—and combine them *always*. There are scores of glorious roses in this division, which generally attain their full excellence, such as *Charles Lefebvre*. There are many others, which, when the season suits them, are not to be surpassed in beauty (such as *Duc de Rohan*, *Marie Beaumann*, and fifty others), but which disappear altogether from our rose shows when drought or damp or vernal frost has been unkindly for them; and these I have omitted, wishing to provide for the young amateur such roses as cannot disappoint, and knowing well that, once successful, he must include them hereafter in his collection—hereafter, when the happiness of growing roses will far exceed those failures and disappointments which, had they met him at his outset, might for ever have destroyed his hopes.

Alfred Colomb is one of the few perfect roses which is *toujours gay*. In colour, a rich carmine, with a crimson glow on it; in size, large, globular, symmetrical.

Baroness Rothschild—one of the most beautiful, and, so far as I have tested it, one of the most reliable of our light-coloured roses, for though short in limb, she is strong and sturdy in constitution. It seems ungraceful to describe a lady thus, but in writing and speaking of roses, one meets with strange antitheses. Of this very rose, and only the other day, a rosarian said to me, "Ah, yes—isn't she lovely!" and then added, with a tender pensiveness, "I do believe that I've given the Baroness more than double her share of—pig-manure!"

(To be continued.)

THE PAMPAS GRASS.

(*ZYPERNUS ARGENTEUM*.)

WHEN I say that this is one of the most valuable and most generally useful of hardy flowering plants, I state what few will venture to gainsay, except, perhaps, those who have only seen it growing on thin, poor, dry soils, stunted and starved; or in exposed situations, where it may sometimes be seen with its foliage blown about and disfigured, and its fine feathery plumes broken and unsightly. Although not over fastidious about soil, to grow it successfully it requires a deep rich one, rather damp than dry. It also likes a sheltered situation, but not one much shaded, and it always prefers a cool to a warm subsoil. Where, therefore, these conditions do not naturally exist, means should be employed to secure them artificially. Even under favourable circumstances the vigour of the plant will be greatly increased by trenching and opening up the soil some five or six feet from the point at which each specimen is to be permanently placed.

Whether employed to ornament the villa-garden, or for planting in or around flower-gardens of greater pretensions, few hardy autumn and early winter flowering plants are handsomer than this; and when well placed on lawns or in shrubbery borders, it is likewise highly effective, lighting up and relieving heavy masses of sombre foliage, after almost

everything else in the way of flowering plants has passed away. By the sides of drives, too, or walks, either singly or in masses, so as to come suddenly and unexpectedly into view, the effect is grand in the extreme.

At Castle Kennedy it has been extensively used for some years past as a decorative plant, and nowhere so successfully as in the American ground, which is about two acres in extent, surrounding a circular piece of water, which covers upwards of an acre. The American ground was formed about twenty-five years ago, and is so arranged as to have Rhododendrons, Azaleas, Kalmias, Ledums, Andromedas, &c., planted in groups by themselves. The water which occupies the centre of the ground is surrounded by a grass terrace and broad grass walk. The dwarfer growing of the shrubs stand nearest the basin, and the taller ones further back, supported behind by fine old evergreen oaks, conifers, &c. Owing to the amount of flowering shrubs, there is almost a superabundance of bloom during the height of the season; but after the end of July there is a blank—a felt want which few plants are calculated so well to supply as the Pampas Grass. Here, in well-drained ground, consisting principally of peaty soil three or four feet deep, sharpened by a liberal admixture of sandy gravel, we have considerable numbers of this stately grass, many of which now form large round masses, measuring from ten to twelve feet in diameter, and from six to seven feet in height, each plant throwing up annually from sixty to a hundred flower-stems from eight to twelve feet in height. It should be mentioned, however, that there is a considerable number of varieties of Pampas Grass in cultivation, some flowering as early as the close of September, others following in succession during the autumn and early winter, while many are still in flower (3rd January), although now somewhat bleached and broken by winter storms. The flower-stems of the earlier varieties have larger and more spreading heads, and are generally a shade browner in colour than the later varieties. The latter also differ much amongst themselves, but they have generally a white and silvery appearance, the heads being compact, and less liable to be broken in stormy weather than those of the early sorts. The sites here for the Pampas Grass, amongst the American plants, were well selected for effect; and during the autumn, when in full flower, in connection with the fine foliage of the rhododendrons and kalmias, the warm fading tint of the azaleas, &c., the whole, backed up and supported by the masses of fine old evergreen oaks and conifers, and reflected by the water on calm days as in a mirror, an effect is produced not easily to be forgotten.

To those who have not had much experience in planting the Pampas Grass, and who contemplate so doing, I would say, never plant in the autumn. Although a comparatively hardy plant when of some size and well established, small plants are easily injured by severe frosts, particularly soon after being transplanted. The latter end of April or the beginning of May is perhaps the safest time to transplant, something, as a matter of course, depending on the locality. Strong plants should only be used; if weak ones have been provided, grow them on in the nursery or reserve ground for a year or two before planting them out in their permanent places.

In situations where game abounds, and where, as is frequently the case, it is desired to introduce the Pampas Grass, if young plants are put out, hares eat them greedily while the leaves are young, and eventually destroy them. By dividing old plants, and keeping large pieces together, they may be safely planted in such situations, being then hare and rabbit proof, as the hard old leaves are too much for them. Plants grown in a nursery or reserve garden for a few years will answer the same purpose; always keeping in mind that, if you want to grow the Pampas Grass quickly, feed it well.

Castle Kennedy, Stranraer. ARCHIBALD FOWLER.

HARDY PLANTS AND TREES.

EAST AND WEST VERSUS NORTH AND SOUTH.

In classifying plants and trees as hardy or tender, writers, I would submit, err somewhat in dividing the climate of these islands into north and south. North and south of the Trent or Tweed such and such plants are hardy or tender. In

your number for December 30th, for instance, one of your correspondents states that fig-trees in the north will barely subsist against walls; whereas, in the south they grow as standards. A more intelligent and practical division of the climate (with an exception for some trees and plants which require more sun than an average northern summer can boast) would be into zones of east and west. The west coast, being exposed to the full influence of the warm currents from the Atlantic, enjoys a temperature in winter many degrees higher than the less-favoured east; and even when the thermometer registers an exceptionally low temperature, plants survive without injury which would infallibly perish in a much higher temperature on the east coast. This is, probably, owing to the fact that the soil is warmed by the constant afflux of the Gulf Stream for many ages. For instance, here (I write from the south-west of Scotland) we never think of affording protection to myrtles, lemon-verbenas, laurustinus, and other delicate things, either standard or against walls. Fuchsias stand out without any covering—the common red sorts grow into huge masses ten or twelve feet high; a gorgeous sight in August. True, these exotics are sometimes killed to the ground. For instance, in the ever-memorable Crimean winter, 1854-55, we had a lemon-verbena, the stem of which measured nine inches in circumference, killed to the ground; but it sprung up, and has again covered the wall which it adorns fourteen feet high.

Last winter was a pretty severe one—we had three weeks good “curling”; yet, in my garden several dozens of yellow coelestarias survived without any care. I have seen a scarlet “Foxhunter” verbena survive; but that was in a bed outside a greenhouse. I write these few notes in the hope of encouraging gardeners and amateurs all along the west coasts to try experiments with some of the many lovely tender things, which may not be so tender after all. Try them first in a good soil against a sunny wall, and if they succeed, experiment more and more boldly with single plants and standards.

Permit me to add a few words about rabbit-proof plants. There are many things which, if afforded protection when first planted, will soon make such robust growth, that they will defy the attacks of these creatures. Mahonia, for instance, and Ootoneaster, Pampas Grass, and the different Berries—of these I speak from experience; and here 22,500 rabbits were killed in eight months. When small and tender, they fall an easy prey; but, if wired round at first, do not seem to suffer. Nothing, I am convinced, is more vulnerable or, indeed, attractive to rabbits than hollies. They will bark trees fifty years old, or five hundred if they could find them.

HERBERT MAXWELL.

The Airlour, Portwilliam, Wigtownshire.

Indigofera floribunda.—Although the Indigoferas constitute a very pretty genus, we rarely see them in good condition in this country: in glass-houses they get but little attention, out of doors they are too tender as a rule, though one, *I. Dosua*, makes a very pretty bush, and *I. floribunda* makes a first-class wall plant. Everybody interested in covering walls with ornamental plants should employ it. It is graceful in habit, the foliage being of a slightly glaucous hue; the shoots droop downwards—an excellent point in a wall plant—and bear abundance of light rosy flowers. A specimen of it flowers every year against the end of one of the glass-houses in the Royal Exotic Nursery, Chelsea. It is one of the most perfect wall plants I have ever seen. Walls eight or ten feet high may be quickly covered with it.—S.

Old Friends.—The plants that come up every year in the same place, like the Stars-of-Bethlehem, of all the lesser objects, give me the liveliest home-feeling. Close to our ancient gambrel-roofed house in the dwelling of pleasant old Neighbour Walrus. I remember the sweet honeysuckle that I saw in flower against the wall of his house a few months ago, as long as I remember the sky and stars. That clump of peonies, putting their purple heads through the soil every spring in just the same circle, and by-and-by unpacking their hard balls of buds in flowers big enough to make a double handful of leaves, has come up in just that place, Neighbour Walrus tells me, for more years than I have passed on this planet! It is a rare privilege in our nomadic state to find the home of one's childhood and its immediate neighbourhood thus unchanged. Many born poets, I am afraid, flower poorly in song, or not at all, because they have been too often transplanted.—Oliver Wendell Holmes.

YUCCAS.

(Continued from page 152.)

YUCCA FLACCIDA.—A stemless species, somewhat resembling *Y. filamentosa*, but smaller, with a downy branching panicle three feet to four feet high. Foliage in close rosettes of leaves, one-and-a-half feet to two feet long, by about one-and-a-half inches broad at the middle, often fringed with filaments on the edges: the young ones nearly erect, the old ones abruptly reflexed at the middle, almost appearing as if broken. This gives such an irregular aspect to the tufts, that it at once distinguishes this kind from any of the varieties of *Y. filamentosa*. It also flowers more regularly and abundantly than its relative, and is exceedingly well suited for groups of the finer hardy plants, for borders, or for being planted in large isolated tufts. N. America.

YUCCA GLAUCESCENS.—A very free-flowering kind, with a panicle three feet to four feet high, the branches of which are short and very downy. Leaves sea-green, about eighteen inches long, with a few filaments on the margins. The flowers are of a greenish-yellow colour, and when in bud are tinged with pink, which tends to give the whole inflorescence a peculiarly pleasing tone. A very useful and ornamental sort—fine for groups, borders, isolation, or placing among low shrubs. N. America.

YUCCA GLORIOSA.—A species of large and imposing proportion, with a distinct habit and somewhat rigid aspect. Flower-stem over seven feet high, much-branched, and bearing an immense pyramidal panicle, of large, almost pure white flowers. Leaves numerous, stiff, and pointed. One of the noblest plants in our gardens, and suitable for use in almost any position. It varies very much when grown from seed—a good recommendation, as the greater variety of fine form we have the better. The chief varieties in cultivation are *Y. g. longifolia*, *plicata*, *maculata*, *glaucescens*, and minor. The soil for this plant should be a rich deep loam. N. America.

YUCCA BUPICOLA.—A species somewhat resembling *Y. aloifolia*, with a stem from four feet to seven feet high, and pale-green leaves eighteen inches to twenty inches long, by one inch broad at the middle, almost erect and frequently twisted, the horny margin being broader and the teeth more distinct than in *Y. aloifolia*. This is not much in cultivation as yet, and will probably be difficult to obtain for some time to come. N. America.

YUCCA TRECULEANA.—This species is one of the most remarkable of the noble genus to which it belongs, from its habit, and especially from the dimensions to which its foliage attains. Like many plants of its family, young specimens differ considerably from those which have reached maturity. Thus, while the former have their leaves bent, generally inflected, the full-grown plants exhibit them erect, rigid, very long, and very straight. The stem of this plant is stout, about ten inches in diameter, furnished on all sides with leaves about four feet long, straight, thick, deeply channeled, acuminate for a considerable length, and ending in a stiff, very sharp point, very finely toothed on the edges, which are of a brownish red and scarious. The flower-stalk is very stout, about four feet long, much branched; the branches erect, from one foot to one foot eight inches long, bearing throughout their entire length flowers with long and narrow petals of a yellowish white, shining, and, as it were, glazed. It is a hardy and very vigorous plant. It is not rare to see on the Continent specimens of more than six and a half feet in diameter. Fine for banks and knolls, placed singly, or for the boldest groups. It comes from Texas.

(To be continued.)

THE PROPAGATOR.

MODE OF TRANSMITTING SEEDS AND CUTTINGS.

The introduction of certain seeds in a fit state for germination has long been wished by cultivators. I have repeatedly tried to get collectors to send home seeds in strong earthen jars, or bottles firmly packed in soil and closely corked, the soil to be taken six or eight inches under the surface, so as to contain the natural moisture only; however, few, I am sorry to say, seem inclined to give this method a fair trial, being rather disposed to send by the old system, viz., in dry paper. As far back as 1834 I introduced in this way acorns of many varieties of American oaks in excellent condition for growing, while portions of the same seeds, brought home in paper and also in canvas bags, did not succeed. Some acorns were also brought home in a box between layers of sphagnum moss, having the superfluous moisture previously wrung out of it. By this method of packing the acorns all succeeded well. Dr. Little, of Singapore, a gentleman distinguished for his horticultural skill, has been very successful in introducing into this country many rare plants, such as *gutta percha* (*Isonandra Gutta*), and many rare and valuable orchids. He seldom

misses an opportunity of sending home seeds peculiar to his district, but it too frequently happens that they are completely dried up before reaching this country. During his visit to Edinburgh, in the year 1870, I told him of the disappointments so often experienced with many of his seeds, and recommended him to try the stone-bottle system. About the middle of November last I had the pleasure of receiving a stone jar from him, filled with palm seeds, firmly packed in soil, all quite fresh and capable of germination. In districts where sphagnum moss abounds, I would recommend it in preference to soil, as it retains the moisture for a much longer time, and is not liable to mould or decay. In sphagnum the radicles of the seed are often slightly protruding when they reach their destination, while the soil, with its natural moisture, keeps the seeds much in the same condition as when sent away. With pulpy or berried seeds, the above methods are by no means satisfactory. I have found from experience that all pulpy seeds succeed best when rubbed out in dry white sand. After being spread out in the sun or wind for a day or two to dry, collect the mass and pack firmly in stone jars, and when they reach their destination, take out the contents of the jars, and cover with soil according to the size of the seeds. By this method, I have frequently sent to Australia, Canada, and other distant parts of the world, the seeds of strawberries, gooseberries, raspberries, brambles, currants, blackberries, laurels, elderberries, thorns, hollies, yews, &c. Any portion of the pulp remaining seems less liable to decay when mixed with dry white sand than with soil or sphagnum. For a long series of years it has been customary to send home seeds packed in charcoal, and I regret to see it still recommended. Such a practice, however, ought to be entirely abolished, as it tends to destroy the vitality of the seed. Unless in the case of seeds with very fleshy cotyledons, few others packed in this way ever grow. It is not necessary that seeds should always be sent home in comparatively dry soil in earthenware bottles. About eighteen years ago, I had some seeds of the Akee fruit (*Bilighia sapida*) sent from the West Indies. They had been put into a large old blacking bottle (after being thoroughly cleaned inside), in a mixture of soil and water, firmly closed with a clean bung-cork, and thickly sealed over. When they reached me, I broke the bottle, and found every seed in a growing state. Each was put in a pot and set in a dark place for a time, light being admitted gradually; they soon lost their pale hue, and are now fine thriving trees. This simple method is also worthy of imitation with many hard tropical seeds. Wide-mouthed glass bottles are also extremely useful to botanical collectors and amateur horticultural travellers. During my annual autumn peregrinations both in this country and abroad, I have kept cuttings of rare stove and greenhouse plants in clean old pickle bottles, in excellent preservation for a fortnight, with a little moss and water, and have always found them to succeed well after reaching home. Alpine plants are easily conveyed from their native habitats by the glass bottle system.—J. McNab, in "Proceedings of the Botanical Society of Edinburgh."

HOW TO RAPIDLY INCREASE NEW AND RARE VARIEGATED PELARGONIUMS.

MANY of the kinds in which the leaf colour is most highly developed are slow of growth, and cannot be readily increased, while single little plants of new kinds, bought perhaps at the rate of ten shillings a leaf, naturally take a long time to yield a stock. Doubtless many of our readers have such plants, and they will probably find the following way of propagating them useful. Generally, variegated pelargoniums are propagated by cuttings, and these strike freely enough; but, as the "plant" of a new kind is simply a rooted cutting, it is obvious that much progress cannot be quickly made in that way. They may be struck as readily from leaves as from cuttings. The way is to cut off the leaves with a portion of the stem—a mere little heel attached to the base of the leaf. We have recently seen cuttings of the most precious kinds of variegated pelargoniums inserted with a "heel" no bigger round than a pea, and in a week they have been well rooted, and sending up vigorous little stems from the eye that was dormant at the base of the leaf when it was cut off. The leaf is only put in just far enough to well cover the bases so that the eye when it starts may not have much earth to push its way through. Insert in light sandy soil, surfaced with silver sand; a watering consolidates all, and there is little more to be done till the young plants are ready to be potted. They may be struck most rapidly in a genial hot-bed or warm moist stove, and may be put in pans, boxes, or small pots. One point requires a little attention: it is

the keeping of the leaves in an erect and natural position. Having so very little support below, the slightest touch might cause them to fall; and if they happened to flag in a dry atmosphere, the leaves would fall down one over another, and perhaps not rise again—accidents which would of course interfere with the success of the operation. By bending one end of a bit of copper wire, so as to form three parts of a ring, and then bending this part back a little, a perfect support is formed for a leaf. It merely requires to be inserted immediately behind the leaf, the crook being so placed under the leaf that the central parts of the blade will rest upon it. This simple contrivance keeps the leaf in as erect a position as if it were supported by a stout stem. It need scarcely be remarked that this mode is only recommended, and only necessary, for the rare and very valuable kinds. In the case of established sorts, and of those of which we can get a stock, all we require to do is to insert the cuttings in the open garden border in the summer and early autumn months.

W.

Rose Cuttings.—I do not strike these, as some do, in pure sand. On the contrary, I take my cuttings and put them into pots or frames in the stiffest turf-loam I can get, which I ram hard and fast round the cuttings. The loam thus treated will retain as much moisture as is required during most weathers. If pots are used, the plan is to let the mould be right up to their brim, and to tilt them a little if there is any danger of too much water getting at them. Beyond this they require no attention, unless it be to set them in some nice half-shady yet airy position favourable to root formation. July, August, and September cuttings will root the same season; October cuttings should either be in a frame or in pots, so that they may be removed there. Water of course, if drought prevails, thoroughly but seldom, as the loam so well maintains the necessary degree of moisture.—A. D.

A Prolific Sweet Pea.—You may perhaps consider it worth while to record in your pages the following facts, showing the marvellous fertility of the sweet pea under favourable circumstances. A single seed of it, self-sown, came up in my garden early last spring, and I have just gathered from it four hundred and sixteen pods, containing two thousand two hundred and forty peas! The plant came up in a single stem, then branched out into four principal trunks (if I may call them so), and these developed into a perfect bush, eight feet in height, and having the appearance of a large cluster of sweet peas from a handful of seed. In addition to the seed gathered, many dozens of the flowers were plucked for bouquets. I may observe that the sweet pea seed which was sown this year by me was unusually small and unproductive in results.—F. L. S. [This fact well illustrates what we have often pointed out—the great superiority of many annual plants when sown in the autumn. Few persons who have not seen the difference would believe it, and numbers who sow their annuals every year in April have but a small idea of the value of these ornamental plants. Whence this difference in the strength and profusion of bloom between annuals sown in spring and in autumn? It comes from the spring-sown kinds being called upon for their bloom and seed before they have had time to extract sufficient nutriment out of the earth for a strong bloom. It is the nature of the greater number of annual plants to vegetate in autumn, and to grow slowly, and gather strength through the long winter and spring, so that by the sunny flowering time they are deeply rooted and strong in leaf and shoot, and with vastly more flowering power, if we may so say, than the plants of the same kind sown in spring. It is useful to bear in mind, however, that we must confine our autumn sowings of annuals to those that are not too tender for our winter; but of the hardy sorts there are a good many fine ones seldom treated right.—ED. Field.]

GARDEN DESIGN.

LAYING OUT OF GROUNDS.

Is it an art or a trade that I propose for discussion? I think it is an art. The backwoodsman would not agree with me; there are many plethoric citizens who would not agree. Good roads, and paths laid where you want them, and plenty of trees—is there anything more than this in the laying out of grounds? Is there any *finesse*, any special aptitude requisite, or anything that approaches the domain of art in managing the matter, as such matter should be managed? I think there is; and that it is an art as yet, in this country, almost in its infancy; and yet an art instinctively appreciated by cultivated persons wherever it declares itself, whether upon a small or a large area.

We have admirable engineers who can lay down an approach road, or other, with easy grades, and great grace—so far as the curves count for grace; and we have gardeners who shall lay down your flower-beds and grounds for shrubbery according to the newest rules, and with great independent beauties in themselves; but it is quite possible that both these classes of workers

may fill their designs admirably, and yet steer clear of the great principles of the art I purpose to discuss. It is an art which takes within its purview good engineering and good architectural work, and good gardening, and good farming, if you please; but which looks to their perfect accordance—which dominates, in a sense, the individual arts named, and accomplishes out of the labours of each a congruous and captivating whole.

Good farming, good gardening, good engineering, and good architecture may stand side by side upon a given estate, and yet, for want of due conception of what the landscape really demands for its completed charm, the effect may be incongruous and unsatisfying. Over and over again a wealthy proprietor seeks to supply the somewhat that is lacking by inordinate and cumulative expenditure: he may thus make outsiders wonder and gape; he may also secure a great assemblage of individual beauties; but the charming oneness of effect which shall make his place an example of taste and a perpetual delight is somehow wanting.

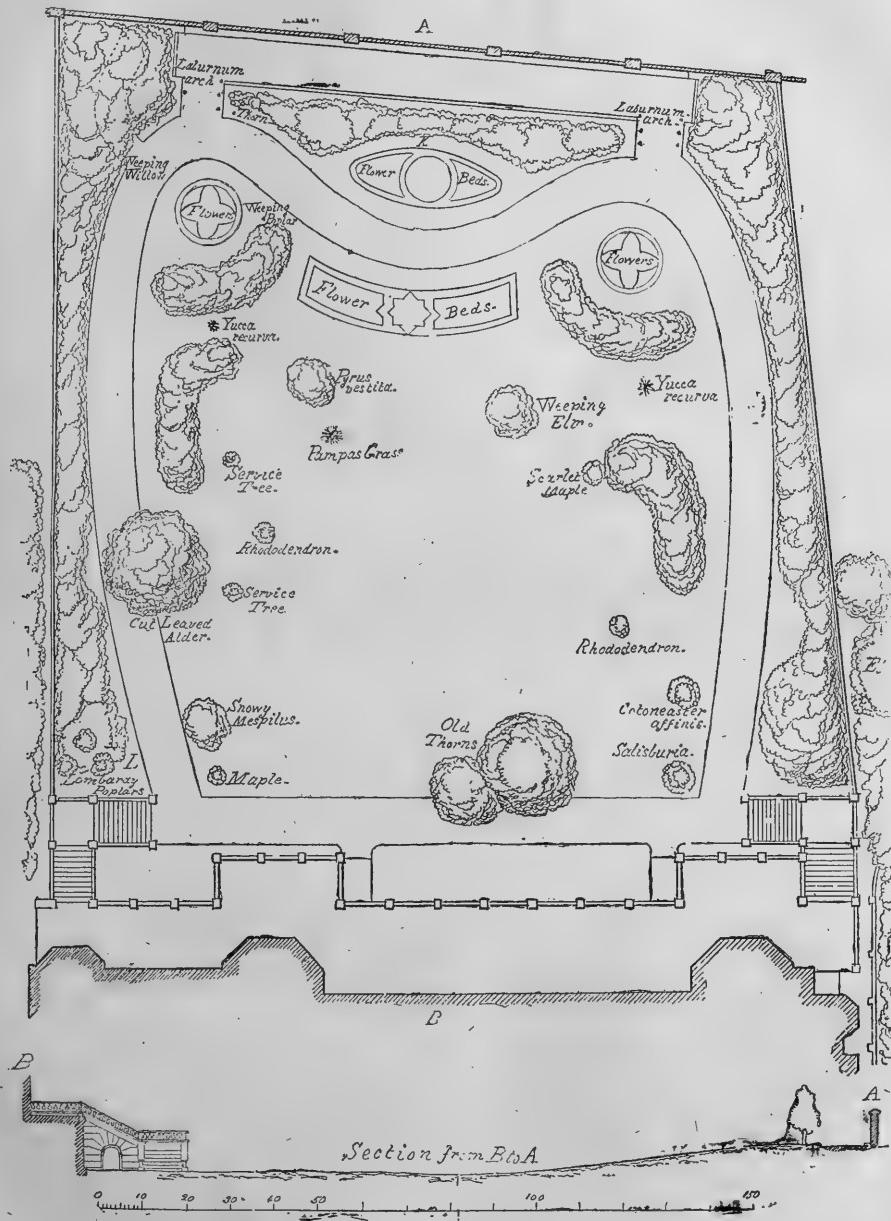

The true art of landscape gardening lies in such disposition of roadways, plantations, walks, and buildings as shall most effectively develop all the natural beauties of the land under treatment, without conflicting (or rather in harmony) with the uses to which such lands may be devoted. Thus, in a private estate, home interests and conveniences must be kept steadily in view, and these must never be sacrificed for the production of a picturesque effect, however striking in itself. Again, in a public park the same law obtains, and any good design for such must show great amplitude of roadway, and broad, open spaces for the dispersal of the multitude. Upon farm-lands, which I hold to be not without the domain of landscape treatment, there must be due regard to the offices of rural economy, and the decorative features may be safely brought out in the shape of gateways, belts of protecting shrubbery, or scattered coppices upon the pasture-lands. Upon ground entirely level, the range of possible treatment is, of course, very much limited; but the true artist in landscape effects can do something even with this; no architect worthy of the name despairs if he is confined to four walls of even height; in his own art, if he loves it, he finds decorative resources.—D. G. Mitchell.

THE GARDEN AT MONTAGUE HOUSE.

WITHIN a stone's throw of the Houses of Parliament is one of the most tastefully-designed little gardens we know of—that of the Duke of Buccleuch, at Montague House. If well-laid out gardens are rare in the sweet, open country, where hill and dale and brook for ever teach their lessons, we need scarcely say they are still more so in our forests of slate and brick. Gloomy, pasty, shaded by miserable, badly-grown trees, and flowerless, from the privet and other weedy shrubs that occupy the ground, London gardens have rarely been distinguished for loveliness of any kind. Sometimes, indeed, a giant plane or some other hardy tree pushes up unobserved and gets its head into the light of day, and after a generation or so of fleeting human creatures has passed away, people look up and see an object as noble as any to be seen in the fairest forests. But then we have to thank the tree and not the garden for this.

The annexed plan sufficiently describes the garden to which we wish now to direct attention. As may be seen by looking at the section running from the terrace of the house to the small one overlooking the Thames Embankment at A, the ground rises slightly towards the river, and on the slight elevation are placed the few flower-beds used. The effect of these from the house is very good. The little lawn, as may be observed, has been kept nice and open, and in the small clumps between it and the walls are many of the most interesting and ornamental species and varieties of deciduous trees and shrubs. Among the older trees which have been carefully preserved, is a remarkable and beautiful specimen of the cut-leaved alder.

The portion of the garden which lies in front of the mansion was likewise laid out at the same time as that shown in our plan, and is also thoroughly well done. An innovation on what is commonly seen in such places is the isolation on the turf of herbaceous plants of fine habit; among these we were glad to see our somewhat scarce and fastidious friend *Bambusa Metake*

PLAN OF THE GARDENS AT MONTAGUE HOUSE, WHITEHALL

growing quite healthfully. This part of the garden is cut off from the street by a wall of young ivy, which is trained up both sides of a strong double galvanized wire trellis. It is the Irish Ivy, the best kind for the purpose.

Hedges, Walls, and Groups.—Hedges have this advantage over walls—they sift the rough wind into soft breezes rather than form eddies. When air in rapid motion hits a solid barrier, a large portion of it often leaps over it; its direction is changed; its force, at times, hardly broken; but when the same air hits a hedge, so much of it is sifted through or entangled in its immemorable meshes, that no eddy is formed. Hence the superiority of living to dead shelters. There is, however, this drawback to the hedge: it lives at the same table as the plants sheltered, and, unless placed well back, it not only stands between them and the rough wind, but likewise between them and their nourishing food. Another objection to hedges is their stiffness and formality amid the flowing grace of a beauteous landscape. They are as objectionable as dead straight walls. This evil may partly be remedied by choosing a line of curved beauty for the hedge. But a line of one breadth throughout, and forming a connected whole, is almost sure to be formal in appearance. A simple mode of breaking up this formality is to vary the thickness of the line; in others instead of a hedge, more or less employ masses of shrubs, now swelling out boldly like the crest of a long wave, and again receding into a single file or so of shrubs or trees. A gracefully varied series of small groups is certainly the most artistic shelter.—F.

INSECTS, BIRDS, ETC.

THE COCKCHAFER.

(*MELOLONTHA VULGARIS.*)

EVERYBODY is acquainted with the cockchafer, therefore we need not describe it; but we have thought it advisable to give figures of it in its various stages. It will be seen from these that eggs of it laid this year do not reach the perfect stage until four years hence—that is in ordinary years; but in a series of very warm seasons or in warm climates it is said to reach maturity in three years; this is, however, exceptional or abnormal. Hence, according as there are few or many in any one year, the produce of that year, developed four years later, will be correspondingly scarce or abundant; but people naturally pay more attention to the years in which they are numerous than those in which they are few, and regard it as an insect returning in numbers every fourth year; so much so that in Germany the fourth year, in which it appears as a scourge, is known by the name of the "flying year"; and, indeed, the flying years and leap years are coincident in Saxony and some other places. It is on the Rhine, the Weser, in Switzerland, and further to the south, that they appear as a triennial plague.

The eggs are large, dirty-white, rather longer than thick, but otherwise almost globular, and are deposited near each other a few inches below the surface of the ground, which is generally selected of loose, rich, vegetable earth. The larvae change their skins several times and grow slowly. They feed upon the roots of any plants growing in their vicinity. In winter, or during a very dry season, they grub very deep down (as much as a yard or a yard and a half), and during the former fall into a state of torpidity; indeed, a severe winter is often prognosticated from the depth of their winter abode. There are differences of opinion as to the period of their life at which the grubs do most damage; some thinking that they are specially injurious during the first two years, when they have most to grow; others (with whom we agree) holding that their worst epoch is when they are perfect, or during the third year (the year before the "flying year"), because they are then older, larger, and require more nourishment. As, however, every year quantities of cockchafers become perfectly developed, larvae of every size are always to be found in the earth. Preparatory to their change from the grub into the beetle, the full-grown ones go further down in the ground, and work themselves a hole, the earth round which becomes compacted into a kind of case or cell, and in it become chrysalids. This happens in July or August, but may be sometimes earlier and sometimes later. In September, October, and the following months, the

beetle may be found almost ready to appear next summer. If undisturbed, they will lie quietly in their cradles, awaiting the early spring, when they will work their way up, and on a fine warm May evening make their appearance through a circular hole in the ground. In the "flying year" one may see in Germany the ground in patches bored so as literally to resemble a sieve. This was very marked in 1864, in the neighbourhood of Halic, when they came in fearful multitudes.

It is not only in its larval state that this insect does mischief; in the perfect state it is also very injurious. The great swarms of 1864 just spoken of, in a week's time left the largest oaks standing leafless. The chafer come out about the beginning or middle of May on the Continent; here a few days later. When newly come out of the earth, they cluster themselves, upon fine warm evenings, on the tops of trees, and begin the work of devouring them. The oak is the favourite food of the perfect insect, and the trees are robbed of their leaves before the underwood; then come the horse-chestnuts, maples, plum trees, poplars, willows, &c. An observer, speaking of the ravages of the perfect insect in France, says, "The ground was almost covered in some parts with the dead bodies of cockchafers; and along one part of the railroad near Rouen, I noticed a wood nearly a mile long quite stripped of leaves by this pest. It is no exaggeration to state that many great towering Lombardy poplars, oaks, and birches were stripped as bare as if it had been a December instead of a fine June morning." Only very few deciduous trees escape them; but the lime and acacia are said to be eschewed, or only eaten last. After all the trees in the place are despoiled, they then pass to herbaceous plants.

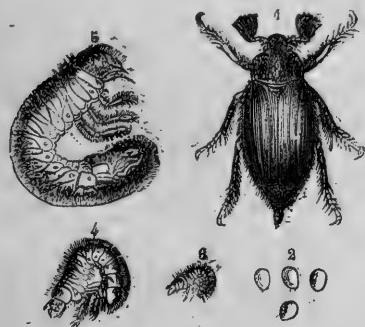

Very soon after the first appearance of the chafer they pair. M. Taschenberg found at the most only thirty developed eggs in the ovary, and this about eight days after the pairing of the insects had taken place, so that the statements of greater numbers being deposited are probably incorrect. From four to six weeks later, consequently some time in July, the grubs creep out of the egg. They keep much together during the first year, and usually cast their skins for the first time after their winter sleep.

In this country they never reach such vast numbers as they do on the Continent; and in Scotland they are sufficiently scarce to make any entomologist who is particular about his localities prize them as rarities.

As regards their destruction: the introduction of starlings into infested districts has been attended with much success. Mr. Booth, the well-known nurseryman of Hamburg, says:—"About ten years ago, we suffered terribly from cockchafers; whole plantations of rhododendrons and conifers being completely destroyed by them. Against such devastation all artificial remedies were more or less powerless: We then adopted the starling plan. We caused 100 breeding cages to be made of the very simplest construction, and in the spring they were all occupied: In what colossal quantities the starlings devour these insects, you will find recorded in "Lang's Natural History." As soon as the cockchafer comes, or is coming, out of the earth the starling is there; it picks the chafer clean out, tapping about on the ground with its beak until it finds it. Beside almost every hole from which a cockchafer has escaped, one might find the wings and whatever is uneatable, proof enough that the chafer's enjoyment of life had not been of long duration. We increased the number of cages, and have now from 175 to 200. We have since then had plenty of cockchafer years, but have not again experienced such injury from them; and in working the ground to a greater depth for them, the number of grubs found is comparatively few."

The remedies which have been proposed and tried, with more or less success, are numberless. They almost all, however, bear upon the dislodging of the insect from a particular spot, rather than upon a more general mode of dealing with them. Perhaps the most efficacious is the collecting of the insects and their grubs. The collecting, however, must be continuous and not intermittent; and must be persisted in, not only in "flying years," but as long as any are to be seen; and to have a fair chance of success it must be followed, not only by one, but by all neighbouring landholders at the same time. In order to obtain such simultaneous action, it has been proposed in Germany that an obligatory law should be passed compelling

united action. In the last flying year (1868) in Saxony, the authorities took this matter up as warmly as could be done, where no law relative to it existed, and they were seconded in the most earnest manner. In the beginning of the year Dr. Stadelmann, Secretary of the Central Agricultural Society of the province of Saxony, had distributed pamphlets in which he demonstrated by figures the immeasurable injury to the economy of mankind which grubs and cockchafer committed, and earnestly begged people to assist in the collection of the same, and, at the same time, sent to all the principal sugar manufactories, landed proprietors, magistrates of towns, &c., a printed form in which the details of collecting, purchasing, the method of destroying, and the uses to which the dead insects might be put, were all shown. Everyone seconded his wishes, and the lists show the enormous figures of 27,709 cwt. of insects destroyed by vapour, hot water, or whatever other remedy was most convenient to hand. Mixed with lime, they were used as manure. The report adds that allowance may be made for a much larger quantity destroyed, but not carefully recorded. A supplement to the above, from some official persons in the province, gives an additional number of 300 cwt., raising the number to 30,000 cwt. By repeated counting we know that a pound of cockchafers contains 530 insects, so that the above figures represent the destruction of an average of 1,590 millions of cockchafers. Allowing that the half of these, consequently 795 millions, were females, whilst in general females predominate in all insect species, and that each

1. Perfect Insect. 2. Eggs. 3. Grub in its First Year. 4. Grub in its Second Year. 5. Grub in its Third Year.

of these had deposited only ten eggs, certainly too low a figure when the favourable weather, &c., are taken into consideration, this universal war prevented the birth of 7,950 millions of grubs. If such a combined and active warfare were continued for another cycle or two of flying years, the cockchafer would become as rare as it has been common for thirty years and more. With regard to the above enormous prevalence of cockchafers in Saxony, it ought to be explained that it may in some measure be due to the extensive cultivation of beetroot, the nutritious and juicy roots of which are greatly liked by the grub.

To proceed with the directions for collecting. For the perfect insect it ought to take place either very early in the morning or on a very rough day, when the chafer are hanging loosely to the trees with drawn-up legs, and when a slight shake or blow with a club or stick will bring them easily to the ground. On warm, sunny days they are very lively from six o'clock in the morning, and on shaking the trees they fly away or rise from the ground in a manner which increases the difficulty and seriously lengthens the task of gathering them and putting them in sacks. Sacking spread out under the trees greatly assists in the speedy collecting, saving time, and saving the trouble of much stooping. The grubs, again, are collected in working the ground. Here the depth at which the insects are lying at the time must be kept in mind, in order that the plough may bring them to light; and when gathered together,

although the impression is correct that they cannot stand the sun they should under no circumstances of weather be deposited in heaps, even upon a firmly trodden path, as the undermost can easily bore their way through the ground again, and a part of the trouble taken will be thrown away. Spread flat upon firm ground with a hot sun shining upon them, they will soon be dead; if there is no sun, they had better be put in some wooden tub, or in a watering-pan.

We may mention another remedy which an experienced French gardener states that he has constantly employed with good results, and which under some circumstances may be worthy of trial. In June, where it is possible, he sows in the garden, particularly infested by cockchafers and where a large brood may be expected, rows of salad, which it is well known the grubs are fond of and by which they are enticed. In August these places are hoed in a hot sun; thus turning up the young grubs gathered round the salad, and, if left exposed, the sun soon kills them. This simple work is repeated several times on a very hot day, and, according to the assertion of our informant, during the four years which followed the "flying year" he had suffered nothing from the grubs.

Another remedy, based upon the baiting system, and of the same nature as we have already described in speaking of the mole-cricket, is described in the *Merserburgher Official Journal*. It seems that it was tried in the "flying year" 1864, in a nursery belonging to the royal forestry at Bischofsrode, comprising one and a half acres of land, and surrounded by high trees, especially by oaks, completely ravished by cockchafers. Just before the flying time, seventeen different spots were artificially prepared as breeding places in the following manner:—Alongside the paths, and near the fences, from three to four square feet of ground were covered with fresh manure from five to six inches high, without mixture of straw or any other material; upon this was laid two or three inches of fresh earth, nicely smoothed down and raked. These spots were carefully watched during the flying season, but, owing to the absence of any bored holes, were left undisturbed until the middle of July, when it was discovered that in those spots exposed to the sun the manure was a living mass of grubs, a quarter of an inch in length, whilst in those places more in the shade the numbers of eggs was inconceivable. These heaps were brought together, and collectively burnt outside the nursery. In regard to this, M. Taschenburg, to whom we are indebted for much of the information here given, justly observes that this method may be very well adapted for forestry, but will not do equally well for gardens or fields. As the cockchafer only lays its eggs upon a free open spot, it is very natural that all such places as were offered by this nursery surrounded by trees should be selected by the female chafer to deposit their eggs; but in an open field or well-cared-for garden, where every place is alike favourable, they would hardly have allowed themselves to be so entrapped.

As might be expected where the evil is so common and wide-spread as on the Continent, there has been no lack of quack remedies in the form of manures, powders, and lotions. To mention these might amuse but could not instruct our readers, therefore we abstain from recording them. A. M.

Rabbit-Proof Plants.—(See p. 136).—Mr. Simpson's experience has reduced the list of rabbit-proof plants to one, namely, the Rhododendron; and Mr. Ingram states (p. 88) that even Rhododendrons do not always escape. The truth appears to be, as stated by Mr. Ingram, that barking trees by rabbits in some places is an acquired propensity. Freshly planted trees and shrubs are certainly more attacked than older plants of the same kinds. Therefore, all freshly planted trees ought to be protected by wire netting, or some guard of the kind, for three or four years after planting; and the rabbits should be kept down as much as possible. When I recommended the Pampas grass as a desirable plant for planting in wildernesses and for homé covers, my mind recurred to some grand old plants of it, which I had seen in Norfolk, to which no ordinary rabbits would do any harm. Most likely they had been protected when first planted, as it was the custom to mat this grass up when first introduced. It is, however, pretty hardy, and a grand subject for planting sparingly, either singly or in groups, on the banks of rivers, lakes, &c.; but it loves a good soil; therefore some pains ought to be taken with it as first.—E. HOB DAY, *Ramsey Abbey*.

THE IN-DOOR GARDEN.

FORCING LILACS.

Few hardy shrubs are more useful or easier to force than the different varieties of lilac. The Persian kinds are generally either grown in pots, or potted up for that purpose, and they form splendid objects for room, staircase, or conservatory decoration, when grown to a single stem like a standard rose, with a crown of any desired size drooping with its weight of floral beauty and sweetness. But if you want flowers for cutting in abundance, hie off into the woods or shrubberies, which ought to be full of charming lilacs. Examine the bushy plants, and count up the terminal buds, sound and plump, from a score to a hundred of them there may be all on one bush. Each of these is a bunch of bloom in embryo. You want it in flower by the end of January. Very well. Up with the plant with a good ball, and transfer it to a hot bed—warm leaves are a capital medium—of a temperature of from 60° to 70°. Plunge the ball overhead in these leaves, and keep it moderately moist. The heat must not exceed 70°—65° being a better temperature. The roots wonder greatly what has happened, and being somewhat impatient of so much warmth, send out scouts to report. Scarcely has this been done, when the buds burst their winter covering, and come forth to hail the spring in a genial mood, in a balmy air of from 55° to 65°.

Under such conditions, a glorious harvest of lilac blooms may be gathered every month or six weeks. I know of no plant that will yield so much blossom with so little trouble in so short a time as the lilac; and it is a universal favourite, and seems to bring more real spring with it than almost any other forced plant. When done with, remove the plants to some cool place under cover till the severe frosts are over; then plant them out from whence they came, and in about three years they may come in again to be forced. Or, better still perhaps, cut the big plants back, pull them to pieces, making of each separate bough a plant, and away to the wood or shrubbery, or rich reserve ground, with the little lilacs to grow into blooming plants once more; then begin again, and gather the lilacs from December to July.

D. T. F.

TORENIA ASIATICA.

THIS is one of the most graceful flowering plants ever introduced to our stoves. Trailing plants are usually attractive; from their freedom of habit, and consequent tendency to grace the interiors of the structures in which they are placed. When we get a free and spreading subject, and, as in this case, a profusion of beautiful bloom, it becomes worthy of more attention than is usually deserved by a tender plant. The Torenia is especially valuable as a basket plant; it is no less useful when allowed to fall in a rich spray of blooming shoots over the edge of the pots, so that, when placed on brackets or elevated shelves, the shoots may fall down far below the pot and so hide it. The culture of the Torenia is simple; its chief requirements are a free, rich, and light soil; the temperature of a stove or intermediate house. The soil may be equal parts of peat and light turf loam, with a mixture of sand sufficient to keep the whole porous, and a small portion of well-decomposed manure. A temperature of 55° to 60° will be sufficiently high during the autumn and mid-winter months; it may be increased with advantage ten degrees, when the sun begins to warm up the houses in early spring. But perhaps the chief point, though a simple one, is the procuring of a regular supply of young plants, as by the aid of these the cool stove, conservatory, or greenhouse may be embellished with graceful free-flowering plants of Torenia during more than half the year. Short-jointed cuttings strike very readily in early spring; they should be inserted in peaty soil with plenty of sand, and plunged in a bottom heat of about 80°; in a month or so they will be struck, and should then be placed in five-inch pots. After this, with cleanliness, in a moist warm temperature they will go on as freely as could be desired. Some-keep them growing nicely the first year, so that by the approach of winter they are well furnished plants in ten-inch pots, and then early in the following year shift them into twelve-inch or fifteen-inch pots, in which they begin to flower in early spring, forming fine large specimens, and continuing in perfection for months. Plants struck in the summer instead of in the spring, and kept at rest through the winter and until March in five-inch pots, are the best to succeed those that are brought in early; they should be placed in their blooming pots or baskets about the end of July or beginning of August, and with a temperature of

about 65° will go on blooming through the autumn, and far into the winter months. As young plants grow and flower most freely, it is best to throw away the old ones, and strike a few pots of cuttings every year. The two-yearly course is not necessary in all cases, excepting where particularly large and fine specimens are desired. If cuttings are struck in very early spring, and four or five put in each ten-inch pot, and these on the upper shelf of an early viney, or any other position near the glass in a warm house, kept clean and freely supplied with moisture, they will soon make fine plants, as they would if placed in baskets under like conditions. The shoots of plants grown on the top-shelf of a lean-to viney, fall freely towards the light, and are, without any training, peculiarly suited for placing on brackets, &c. The plant may be readily trained over trellises, but is not so desirable in this form. A more natural and pleasing way is over a flat, spreading wire frame, or scrambling through a few twigs, or through the top of a young larch thickly set with branchlets; but the best way is, without any training at all, to allow the branches to fall loosely over the edge of the pots or baskets.

J. B.

Euphorbia Jacquiniflora a Grand Climber.—We have at the present time an example of this beautiful plant in full bloom, trained on the back wall of a plant-stove. It covers an area of 160 feet, and bears more flowers of finer quality than I ever grew before on twenty plants in pots. Some of the wreaths are quite three feet in length, and the stems on which they are borne are as thick as a man's thumb. As it is not desirable to have the whole of the blooms so large, where cut flowers are an object, we adopt the pinching system. This is done when the shoots are about half grown; every other shoot is topped, causing it to throw out a number of smaller shoots, which flower freely, and are much more convenient for cutting purposes; besides, the plants look much more handsome than when bearing all the bloom at the top. I observe, also, that the pinched shoots retain their foliage much better at the base of the plant than when they are allowed to run at will.—*G. J. G., in "Gardener."*

Tea-Scented Noisette Roses for the Camellia House.—In Maréchal Niel, Rêve d'Or, and Céline Forester we seem to have acquired what may be called "Evergreen Tea-scented Noisette Roses." Rose-growers will understand the value of this foliage-retaining property on recalling how the merits of Lamarque, Solfaterra, and Triomphe de Rennes are detracted from by reason of the branches of these kinds becoming bare and leafless at certain seasons. Let us, then, use these grand yellow evergreen roses for shading our frost-excluding yet temperate camellia houses. Let them run up the pillars, and, when reaching the glass, spread the branches out about a foot beneath the roof. Anyone who has seen the fine golden ovals ("roe's eggs all yolk," I think Mr. Hole once called them) hanging down from some branches, rambling just under the glass of the fine conservatory at The Poles, near Ware, could hardly doubt that the rose was there at home. Close to the glass, intercepting the sunlight from the shade-loving plants below, these roses seem to enjoy themselves thoroughly. The moist atmosphere required for the Camellias is just what the leaves like, and just what red spider, all roses' indoor enemy, does not like. Care must be taken to supply them at the root with all-important nourishment in the shape of solid and constant supplies of mild, cooling liquid manure, this to induce every year strong, vigorous second growth. It is from these vigorous shoots that the fine flowers are produced, and the problem to solve is how to get annually this fresh supply of flowering wood. In the rose house here we have produced strong breaks by bending down shoots after flowering, and nipping the bark just above a good eye; but in a closer, more moist and congenial atmosphere strong root action should, with summer pruning, produce plenty of flowering wood. In pruning, thin the old wood well out, leaving at almost full length thin, long, or sappy, succulent branches. In April and May a cloud of yellow clusters should hang from the roof, a fresh abundant wood growth succeeding the flowers, to be ripened off with the camellias.—*Geo. Paul, Cheshunt, in "Field."*

Near Relations.—Relations are veryapt to hate each other just because they are too much alike. It is so frightful to be in an atmosphere of family idiosyncrasies; to see all the hereditary uncomeliness or infirmity of body, all the defects of speech, all the failings of temper, intensified by concentration, so that every fault of our own finds itself multiplied by reflections, like our images in a saloon lined with mirrors! Nature knows what she is about. The centrifugal principle which grows out of the antipathy of like to like is only the repetition in character of the arrangement we see expressed materially in certain seed-capsules, which burst and throw the seed to all points of the compass. A house is a large pod with a human germ or two in each of its cells or chambers; it opens by desiccation of the front-door made by, and projects one of its germs to Kansas, another to San Francisco, another to Chicago, and so on; and this that Smith may not be Smitten to death and Brown—may not be Browned into a mad-house, but mix in with the world again and struggle back to average humanity.—*Oliver Wendell Holmes.*

THE CULTURE OF PITCHER PLANTS.

AMONG the wonders of the vegetable world these are not the least wonderful. When we speak of pitcher plants we do not mean the *Sarracenia*, which produce trumpet-like or cornucopia-formed leaves, nor the *Cypripediums*, which have pitcher-like flowers, but veritable pitcher plants, which produce perfect leaves, and then from the end of each, hanging by a long slender cord, a pitcher—some large enough to hold nearly a pint of water, and others scarcely larger than a child's finger. The use and economy of these pitchers it is difficult to define, and, how the water gets into them is a puzzle to all. The mouth of each pitcher, it will be seen, is covered with a lid, in many cases fringed with hair-like appendages, through which it would be difficult for either rain or dew to pass. The pitchers again are not suspended by the mouth, but by the base, and therefore it is impossible that the water can run from the leaf to the pitcher, as is supposed by some. The true explanation appears to be that the plant has the power of secreting water so long as it is surrounded by an atmosphere the state of which is favourable to its growth, but in an arid atmosphere pitchers cease to be formed; and if the pitchers that are formed are regularly day by day deprived of their water they soon become unhealthy and perish.

Travellers in the tropical countries of which these plants are natives are glad to plunge into the swamps to slake their thirst with the water which they find in these pitchers; and it is said that some birds and small animals also resort to the pitcher plant for a supply. So far as we have tasted it, the water is perfectly pure and sweet, and must be welcome to the wayworn traveller under a torrid sun. For the opportunity of figuring this superb specimen of *Nepenthes Rafflesiana* we are indebted to Mr. Speed, the superintendent of the Duke of Devonshire's noble gardens at Chatsworth. There, in the Amherstia house, which is necessarily maintained in a moist tropical temperature, the pitcher plants are grown perhaps better than in any other place in England, many of the plants forming a dense thicket of branches 5 to 15 feet high. We are also indebted to Mr. Speed for the following account of his method of cultivation. He says: One cannot help regretting that this singular and very interesting tribe of plants is not more generally found in select collections; but I suppose it arises from some fancied difficulty in their cultivation, and the idea that they require a high temperature, whereas any person who has the convenience for growing pines or orchids may also grow pitcher plants.

The *Nepenthes*, like many more rare and valuable plants, have been killed with kindness, most people imagining that they must be screened from every ray of sunshine, and also from direct light. Keep a plant in a close, moist atmosphere, with regular shading from every gleam of sunshine, and you may get luxuriant growth, but no pitchers; insure it regularly to full light from this time forward, shading only for a short time in the hottest part of the day, and then with a very slight shade, and almost every leaf the plant makes will produce a pitcher. This, I think, is strong proof of the necessity for direct light to these plants. Last year I tried an experiment with some plants of *N. phyllanthera*, which was rather shy in bearing pitchers in the Amherstia house, where it was much shaded; but in a large roomy house, with no shading, it grew and produced pitchers very freely—so much so, that it was by far the best plant I had of that variety. The plant of *N. Rafflesiana*, engraved, was grown in the house devoted to Vandas, and was kept close to the glass.

To cultivate the pitcher plants successfully, certain rules are necessary, and the first and main one is that they must never know the want of water; then the temperature must be sufficient, and the atmosphere during the growing season must be moist. If once a plant is allowed to flag for want of water, it will take a long time to resuscitate it. The pitcher plants will grow either in pots or hanging baskets, or they may be planted out in beds or boxes specially prepared for them. Here we grow them in different ways, but I think the larger-pitched kinds, such as *N. Rafflesiana*, *Hookeriana*, and some of the hybrid varieties which have recently been introduced, are most effective when grown in hanging baskets or handsome vases. Of course, with suspended baskets the greatest watchfulness is required in watering. For choice I prefer pots, but these should be of an ornamental character, or otherwise they should be placed in vases when the pitchers are in perfection.

Given a healthy young plant in a four or six inch pot in spring, I take some rough fibrous peat and break it into pieces about the size of eggs; then sufficient sphagnum (which has been previously scalded), some clean broken crocks and silver sand added to make a light generous mixture. The pots are best drained by placing an inverted small pot over the hole at the bottom and then filling in around it with broken potsherds, so that the pot shall be about one-third full, covering the whole securely with sphagnum; then fill in your compost, which it is scarcely necessary to remark should be made warm before using; place the plant in the centre and press the compost closely, but not firmly, around it. The collar of the plant at the time of potting should be two inches below the rim of the pot, so as to admit of top dressings, which are of great importance in the growth of the plants. The best compost for this purpose is cow manure rubbed quite fine, and some half-decomposed leaf mould. Give a dressing a quarter of an inch thick when the plants seem to require assistance, and then cover over with live sphagnum, which imparts a nice finish to the plant.

This is a capital time to commence the cultivation of *Nepenthes*, for, started away in the early spring, and thoroughly inured to light and air, they will by July and August be richly fur-

nished with finely-coloured pitchers. Water must be given regularly in sufficient quantity, of course taking care that it is of the right temperature. Cold water would be fatal at once. Should the sphagnum top-dressing become shabby, replace it with fresh, and add the top-dressing as frequently as the plants seem to require it. The plants once established, the syringe may be used freely night and morning; water copiously at the roots, and in bright weather it will be found a capital practice to sprinkle the paths, borders, and other spaces frequently throughout the day—in fact, maintain a moist but not a close atmosphere.

Plants that have been much shaded must not be exposed to bright light suddenly, but they must be inured to it gradually, until at last a piece of thin Nottingham net, to break the fiercest rays of the sun, will be sufficient shading for them at any season. I commenced this treatment twelve months ago, and I have been rewarded with double the number of pitchers ever seen upon plants of the same size before, *N. Hookeriana* having given me fifty well-developed pitchers, and *N. Rafflesiana* thirty, while of the smaller kinds I have had pitchers in thousands. I leave these facts to speak for themselves. I have said nothing as yet of temperature; but a minimum of 65° by night, rising to 85° or 90° by day with the sun heat, will be the right thing.

If the plants can stand over a tank of warm water or evaporating troughs, so as to get a gentle, moist bottom heat, it will be very suitable for them; indeed, a friend informs me that one of the best plants he ever saw had thrown its roots into the evaporating trough of a hot-water pipe, where the temperature must frequently have been as high as 90°, and yet the root luxuriated, being several feet long, and a complete wig of fibres.—*Field.*

THE LILY OF THE VALLEY IN POTS.

ALPHONSE KARR says the flowers of the lily of the valley are like pearls in shape and lustre, but like pearls perfumed. Considering that it is a plant wild in abundance in some parts of this country, those who pay a high price for it every year for forcing may well liken it to such precious gems for an additional reason. And the plants, too, are often thrown away as useless after having been forced. We have to describe a plan of culture much better and cheaper than that in common use, and certain to produce finer plants of lily of the valley than are often seen even at spring flower shows.

To begin with, it would be as well to secure "imported plants," as by doing so we insure a bloom during the current spring, and commence at the same time to accustom the plants to the treatment which must be annually pursued. However, it is by no means necessary to buy imported plants, as those potted up from the plantation in the open ground will do; but they must get a year's residence in pots before flowering well. The forcing of this lily is so very simple that we need not describe it here. In a warm viney, in a melon or cucumber frame, on a shelf in a forcing-house, or in any like position, it comes into bloom with facility, provided always that the plants are furnished with flower buds. It is the want of these that we have to guard against. Given plants well furnished with prominent roundish buds, bringing them into bloom in a heated structure is a thing that anybody can perform; but no skill will suffice to make presentable plants without these well-filled "crowns." Now the secret of getting these desirable buds consists in allowing the plants to make a perfect and healthy growth after flowering. By causing them to do that, we secure finer plants than are imported for the especial purpose of forcing. Judging from the plants seen at shows, and in many gardens, they are not kept from year to year. The finest plants we have ever seen are now in bloom, and have been regularly forced during the past five years. Once out of flower, instead of being thrown aside in some out-of-the-way place in the open air, they are placed in a comfortable frame or on the shelves of a cool-house near the glass—anywhere, in fact, where they may have perfect protection, and can continue their growth without the slightest check. Should anyone think that, from being hardy, they may be placed in the open air with impunity before the frosts and all danger are gone, and act upon it, a decided mistake will be committed. No matter how hardy a plant may be, once excited in a high temperature, in winter or spring, they must be retained therein till genial weather arrives, or they will be destroyed or much injured. It is just like what occurs with the hyacinth, and also with other forced flowers. Generally they are exposed to cold, and neglected or badly treated, and therefore flower very poorly and weakly the year afterwards, so much so that people usually throw them away altogether as useless; whereas, if placed in cold frames, and permitted to make their growth and die down un mutilated, they would prove quite as good as at first. In the case of the lily of the valley a much better result is gained by this management than from the expensive and specially-prepared crowns. If brought into bloom very early, say soon after Christmas, the plants should be allowed to grow away in any place that may be spared for three months. Those that are in bloom now, or going out of it, should be kept in such a position as that before-named for about two months to come, when they may be placed, in the open air, plunged in coal ashes in some sunny spot, and there allowed to ripen and gradually die down to rest. Once that stage has arrived, it matters little where they are; but the most convenient plan will be to leave them plunged in the coal ashes, and, as batches are wanted from time to time to introduce to the forcing house, take them up, clean the pots, refresh their surfaces, and place them in the desired position. The chief point once settled, there remains the potting and little else. Should the plants

when in flower be closely packed in rather small pots, as is usually the case, it will be better to place them in pots a size larger, not mutilating the roots more than may be necessary for efficient potting. And when these plants in their turn fill the larger pots so that re-potting seems again desirable, each specimen may be cut in two and the stock increased. It is not desirable to grow them in pots more than eight inches across or thereabouts, unless in special cases, where a wide pan or pot is desired. Another advantage of this mode of culture is, that the plants grown after it are furnished with abundance of healthy large leaves expanding with or before the flowers. The plants usually seen are but sparsely furnished with leaves while the flowers are out. Thus, if any one thing be clear it is that buying lily of the valley roots from Continental gardens is unnecessary. If, beginning with roots potted from the open garden, we should select the plumpest and most likely crowns, try and get a few flowers from them during their first spring in pots, and in any case treat them so as to secure a perfect bloom the following season. Every second year would suffice for the re-potting or dividing of the plants. J. B.

Succulents for Cool Greenhouse.—I shall be glad if you will name such succulent plants as I may grow in a cool greenhouse?—*Alpha.*—[Mr. Croucher, who is very well acquainted with these plants, obliges us with the following list, viz.:—

<i>Aloe picta</i>	<i>Echinopsis oxygona</i>	<i>Kleinia tomentosa</i>
„ variegata	<i>Zuccariniana</i>	<i>Mammillaria stellaris</i>
„ serrulata	“ <i>taibifolia</i>	“ <i>decipiens</i>
„ heterophylla	“ <i>Scabridissima</i>	“ <i>diabolorum</i>
Agave, any of them	<i>Echinocactus californicus</i>	“ <i>dens</i>
Anacampseros—arachnoides	<i>Scopa</i>	<i>Parkinsonia</i>
A. rotundifolia	<i>Echinocereus pectinatus</i>	“ <i>auricarpa</i>
Cactus strigosus	“ <i>Laborei</i>	“ <i>spinosissima</i>
„ cinerascens	“ <i>texensis</i>	“ <i>gracilis</i>
„ repens	<i>Microstelma</i>	<i>Opuntia humilis</i>
Gasteria	<i>Bowieana</i>	“ <i>missouriensis</i>
„ maculata	“ <i>leptophylla</i>	<i>Clavarioides</i>
Cotyledon coruscans	“ <i>verrucosa</i>	“ <i>cristata</i>
„ pulverulenta	“ <i>glabra</i>	“ <i>vulgaris</i>
Crassula, facta	“ <i>undata</i>	“ <i>microdasya</i>
„ cordata	“ <i>albicans</i>	“ <i>cylindrica</i>
„ perfoliata	Haworthia	<i>Pachiphyllum bracteatum</i>
„ erinacea	“ <i>attenuata</i>	“ <i>rosea</i>
Echeveria fulgens	“ <i>tessellata</i>	<i>Sempervivum holochrysum</i>
„ metallica	“ <i>spiralis</i>	“ <i>squamiferum</i>
„ glauca	“ <i>radula</i>	“ <i>spathulifolium</i>
„ retusa	Kalanchoe	“ <i>aureum</i>
Echinopsis multiplex	“ <i>fulgens</i>	“ <i>Haworthii</i>
Erysimum	“ <i>repens</i>	

THE ARBORETUM.

ON TREE MANAGEMENT.

ANYONE observing timber trees in woods and in hedgerows as he passes by rail through any fifty miles of England can hardly fail to be struck with the absence of anything like method in timber management. He may find some exceptions to this general rule in some few woods which are of sufficient magnitude to return a regular yearly income. But, even in these cases, the knowledge of the subject is almost invariably inferior to that displayed in the culture of land for ordinary purposes. Two distinct systems are followed, both equally injurious to the general good: in one district everything is cut down; in another, everything is left to stand. Here the trees are injured by indiscriminate crowding, good, bad, and indifferent, in which case the good are the sufferers. On the other hand, whole districts are dismantled of their fairest ornaments, and neighbouring crops are left to starve from the destruction of their natural shelter. In both instances, the largest profit which can be derived from land by the judicious admixture of agricultural and timber crops is lost to the individual proprietor, and, of course, through him lost also to the country.

Farming and timber-growing are considered by some to be antagonistic interests; but, if common sense were allowed to arbitrate between them, the two would be closely and firmly allied friends. This injurious war of interests is clearly apparent in the two systems to which we have already alluded. In one district, some large landed proprietor, devoted to farming only, cuts down every stick on his estate. The tree that is venerable from age, but useless as property, and the straight growing sapling, which is yearly bringing the highest value to the land is capable of, share the same fate. A clean sweep is

made—a cultivated desert created. Angry indeed is the neighbouring lord, who expresses himself not in words, but in trees. In this case, the noblest specimens stand inconspicuous in a crowd of the mean and the worthless. And thus the systems act and react on each other, converting our pleasant England into a starved waste or a badly-regulated wilderness. "We want more light." A new system must be commenced, by which the annual value accruing from timber may be secured to individual proprietors as income, and through them to the country.

The value of an estate well covered with timber is worth more by many thousands of pounds than one destitute, or nearly so, of trees; yet trees, for the most part, are allowed to grow haphazard. Though loved for their beauty, they are treated with supreme neglect. I venture to assert—and I could furnish half-a-dozen examples of what I say in any one of the midland counties—that the mismanagement, or rather, non-management, of timber on the lands of many large and rich landed proprietors is such, that they would not dare to have their cereals or other crops cultivated in the same style. Such neglect would excite public attention.

The cause of this state of things is not far to seek. I have alluded to the high farming crotchet which sacrifices everything to agricultural produce. This is, however, not the only cause. Timber is nobody's business. Sometimes it is looked after by the proprietor himself, or it is left to a land agent, a bailiff, or a tenant. Of these, the first has too much on his hands to do the work; the second considers agriculture to be the real interest concerned; the third at present is a foe avowed and deadly. All three are generally indifferent foresters. What care they for the eulogiums of Evelyn, Loudon, or Brown?

Another fruitful source of evil is, that timber is generally regarded as so much ready money, not as a regular income. It is felled on emergencies, not at stated periods or on a systematic plan. No regular succession of trees is kept up. Some landed proprietor gets into difficulties—there is a big cutting down. His successor is well-to-do, and loves trees—there is a big planting. How often do we find trees submitted to the axe at their most growing age, whilst on a neighbouring estate, the proprietor will preserve elms that, being past their prime, are yearly shattered by the winds?

Another result of the want of a recognised system is, that in all other businesses there is capital to fall back upon. No sort of property can be managed well unless the requisite amount of labour is expended upon it at the right time. There must be something beyond the profit of the business itself, or profit itself will be the loser. This principle is, however, not applied to trees.

We must not omit the evil that results from a want of uniformity in the views which govern this kind of property. There are certain rotations of crops both in horticulture and in agriculture, and tenants who succeed each other go on recognised principles, and seldom entertain theories widely different from each other. Their profession is land management, which is an understood thing; but, with timber the work is done all manner of ways, and the least profit which can be produced from the timber-growing soil may fairly be expected.

WALTER JONES WHITMORE.

EFFECT OF FROST ON CONIFERS.

It is known to those who have had much to do with the planting of the less hardy conifers, that many of them can be got up to form fine specimens, if planted on sloping ground, avoiding either very high or very low situations. A west or northern aspect will be found most suitable, while east or south aspects should be avoided, because of the liability that the tender shoots may be killed through being suddenly thawed by the sun's rays striking them while partially frozen. Many years ago I remember visiting an extensive provincial nursery, where large quantities of silver firs were grown beneath the shade of large fruit trees. The silver firs were remarkable for their fine leading shoots and general health. In a neighbouring open break in the same nursery there were many silver firs of the same age to be seen with scarcely a leading shoot, stunted and unhealthy, and all but unsaleable. The difference arose from the protection of the fruit trees. This is no exception to a general rule; for, as is well known to nurserymen and foresters, the silver fir is liable to be damaged by late spring and

summer frosts till it reaches the height of two, three, or four feet, after which, like many other conifers, it proves to be quite hardy, as many fine old trees scattered over the country amply prove. I believe the same results may justly be anticipated from some, if not many, of the spring-tender conifers which have of late years been so widely spread over the country, some succeeding in less, others in more favoured localities. No doubt there are numerous parts where it would be only labour lost to attempt their cultivation; but where they are likely to succeed, any trouble taken in nursing them is far more than compensated by the possession of well-grown examples of such interesting and beautiful trees. Anyone now visiting the pinetum at Castle Kennedy would have an opportunity of seeing the effects of the late spring and early summer frosts on whole avenues, as well as on numerous specimens, planted throughout the pinetum, of what are generally considered spring-tender conifers, the plants varying from four to upwards of thirty-five feet in height. The young growths on the lower branches have generally been injured to the height of from two to upwards of three feet; while those on the upper branches have, with few exceptions, escaped uninjured. The following species have suffered in this way: *Picea Pindrow*, *P. Webbiana*, *P. ciliata*, *P. cephalonica*, *Abies Morinda*, *A. Brunonianæ*, &c. The *Picea Webbiana* avenue, perhaps better than any of the others, illustrates what I am desirous to explain, viz., the probability that many of the spring-tender conifers, if slightly protected for few years after being planted, will ultimately prove hardy in favourable situations. This avenue stands in part on level, and in part on hanging ground. Those on the hanging ground have suffered the least—very little indeed, except where the morning sun strikes them, and then very slightly, and only where the trees are tall, about half-way up from the ground, from their being suddenly thawed by the rays of the morning sun alighting on them. Those growing on the level ground have the young shoots only injured to the height of about three feet on the east and south side where partially exposed, and to the height of barely two feet all round the shaded sides. The trees in this avenue are from about fifteen to twenty-seven feet in height. The effect of the frost-line is here so apparent, that it strikes the eye and attracts the attention of the most casual observer. Above the frost line the trees are in perfect health, many of them carrying a few of their lovely purple cones, and making leading shoots of upwards of two feet in length. It is well known that on still, calm, frosty nights, in low-lying or level situations, the cold air becomes the heaviest, and settles down above the surface of the earth, and probably, if properly tested, it would be found to carry a larger amount of aqueous vapour than does the stratum of atmospheric air a little above it; otherwise, I can hardly suppose that the difference in temperature would be sufficient to kill the young growths to the height of two feet or three feet above the surface of the ground, while those a little higher all but escaped uninjured.—*Archibald Fowler, Castle Kennedy, in "Florist and Pomologist."*

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Trees, Shrubs, &c., for the Sea Coast.—What are the best shrubs, flowers, trees, &c., to plant near the seaside?—**OMEGA.**—[*Tamarix Pinus austriaca*, *P. pinaster*, *Cupressus macrocarpa*, *Iris* in great variety, *Eunomus*, *Laurus*, *Myrtes*, *Escallonia*, *Rosemary*, *Arbutus*, *Phillyrea*, *Baccharis halimifolia*, *Lycium barbarum*. As to flowers, nearly all hardy herbaceous and alpine plants will thrive. All the varieties of the carnation, picotee, pink, &c., are particularly happy near the sea.]

New England Elms.—Nobody knows New England who is not on terms of intimacy with one of its elms. The elm comes nearer to having a soul than any other vegetable creature among us. It loves man as man loves it. It is modest and patient. It has a small flake of a seed which blows in everywhere and makes arrangements for coming up by-and-by. So, in spring, one finds a crop of baby-elms among his carrots and parsnips, very weak and small compared with those succulent vegetables. The baby-elms die, most of them, slain, unrecognized or unheeded, by hand or hoe, as meekly as Herod's innocents. One of them gets overlooked, perhaps, until it has established a kind of right to stay. Three generations of carrot and parsnip-consumers have passed away, yourself among them, and now let your great-grandson look for the baby-elm. Twenty-two feet of clean girth, three hundred and sixty feet in the line that bounds its leafy circle, it covers the boy with such a canopy as neither glossy-leaved oak nor insect-haunted linden ever lifted into the summer skies.—*Eliza Vener.*

The Oaks of Europe.—According to a recent return, oak timber is rapidly disappearing from Europe. In France, since 1669, no oak has been felled until full grown—that is, until within thirty years of its probable decay. The consumption of oak timber in France has doubled during the last fifty years. In 1866, £170,000,000 worth was consumed, of which £500,000 worth was imported, against £5,000,000 worth consumed in 1820, of which £400,000 worth was imported. France requires every year 15,000,000 cubic feet of oak timber for wine casks, 600,000 for her fleet, 150,000 for railway cars, and 750,000 for building purposes. In 1826

the total value of imported staves was £800,000; to-day the total value is £5,000,000. A similar increase of the importation of coal for the next thirty years would probably double the price. France, after losing Alsace and Lorraine, contains 135,000,000 acres, of which 20,000,000 are covered with forest. In Norway, the Administration of Forests declares that it is necessary to stop the cutting down of timber. The same enormous consumption is going on all over Europe. Holland and Belgium are nearly denuded of timber, and are large importers. North Germany is rich in forest, but within half a century has begun to cut down young trees. Austria has sold her forests at auction since railways have been introduced. Spain and Greece are almost woodless.

Extraordinary Root of a Tree.—An instance having just come under my notice of the length to which the root of a tree will grow under peculiar circumstances, it appears to me to deserve being recorded, so far exceeding as it does that generally supposed limit, viz., the height of its parent tree. The circumstances are these.—A long stone wall runs by the side of a road near here, behind which an old hedge ran parallel with it. The owner decided on stocking up the hedge, and while doing this the man employed found a root growing between that and the wall—sometimes close to the surface, at others a foot or so in depth. It had started from a Worcestershire elm in the hedge-row, and for some distance he kept hacking it to pieces as he proceeded, till at length, being struck with the strange distance it was running, he informed his master of it, who desired him to get up the remainder entire, which he did, and the piece measured 75 feet in length (which I now possess). The rest of the distance it had run, when measured afterwards, amounted to 198 feet, making up 273 feet altogether. I went myself to inspect the course of it, and found that, could the whole have been measured, it would have amounted to considerably more; for, after it had proceeded as described, it had come to another tree, which, growing up against the wall, had arrested its course, and forced it to turn beneath the wall, and so under the road, which prevented it being measured any further. The diameter of the root throughout its whole course was about one and a half inch, causing it to have the appearance of a leaden pipe. At the extremity where it was lost it had tapered to about one inch, and it had scarcely a rootlet or fibre growing from it all the way. The tree from which it grew is not more than forty feet high, and one and a half foot in diameter; and the wall which (with the hedge) had confined it to its course, may have been built about fifty years.—*J. Brooke, Houghton Hall, Skipton, in "Field."*

Sermons in Trees.—I have brought down this slice of hemlock to show you. Tree blew down in my woods (that were) in 1852. Twelve feet and a half round, fair girth; nine feet, where I got my section, higher up. This is a wedge, going to the centre, of the general shape of a slice of apple-pie in a large and not opulent family. Length, about eighteen inches. I have studied the growth of this tree by its rings, and it is curious. Three hundred and forty-two rings. Started, therefore, about 1510. The thickness of the rings tells the rate at which it grew. For five or six years the rate was slow, then rapid for twenty years. A little before the year 1550 it began to grow very slowly, and so continued for about seventy years. In 1620 it took a new start and grew fast until 1714, then for the most part slowly until 1786, when it started again and grew pretty well and uniformly until within the last dozen years, when it seems to have got on sluggishly. Look here. Here are some human lives laid down against the periods of its growths to which they corresponded. This is Shakespeare's: The tree was seven inches in diameter when he was born; ten inches when he died. A little less than ten inches when Milton was born; seventeen when he died. Then comes a long interval, and this thread marks out Johnson's life, during which the tree increased from twenty-two to twenty-nine inches in diameter. Here is the span of Napoleon's career; the tree doesn't seem to have minded it. I never saw the man yet who was not startled at looking on this section. I have seen many wooden preachers—never one like this. How much more striking would be the calendar counted on the rings of one of those awful trees which were standing when Christ was on earth, and where that brief mortal life is chronicled with the stolid apathy of vegetable being, which remembers all human history as a thing of yesterday in its own dateless existence!—*The Autocrat of the Breakfast Table.*

Trees for Seaside Towns.—We are about forming a committee for the purpose of planting trees along our otherwise beautiful streets, promenade in front of the sea, and in other parts of our town. I should feel exceedingly obliged if you will kindly let me know what trees you consider the best for us. We can provide good soil for planting. Very high winds prevail at times; many of the places would be exposed, others sheltered and warm. There are roses and other flowers out in some of the gardens now.—T. W., *Llandudno.*—[Mr. Barron, of Sketty, near Swansea, who has much experience of tree growth on the coast of Wales says that "among the best trees for street planting are elms; and, indeed, for avenues and promenades generally there is no tree to be compared with the elm. There are the different varieties of elms, some with light variegated leaves, others again having purple foliage, some light green, with small leaves; others with large handsome foliage, and almost every variety a sure and steadfast grower in any situation. It will stand exposure better than most trees, because its

roots take strong hold of the ground, and it will grow in our smoky streets, and make headway on our sea-shores. No doubt there are many other varieties of trees suitable, to some extent, for avenues, &c., such as the lime and horse-chestnut, &c.; and where exposure is not so great, the *Ailanthus glandulosa* is a very handsome tree, with large and beautiful tropical-like foliage. *Acer Negundo variegatum* is another lovely tree, and where sheltered it grows rapidly. *Populus alba* is the best variety of poplar for street planting, or ornamental planting in general, because of its handsome foliage, and it grows as freely as the Black Italian. Curiously enough, the *plane* (*P. orientalis*) does not succeed well in Wales; and London is almost its special home. The great thing is to have "seasoned" trees, making elms the mainstay, and balancing and selecting the varieties as the work proceeds. It may be added, that whatever is undertaken in the way of town planting, whether by the sea or not, should be done well.—January 1, 1871.]

GARDEN STRUCTURES.

MR. BESSEMER'S CONSERVATORY.

The most remarkable conservatory erected of late near London is that in Mr. Bessemer's garden at Denmark Hill, Camberwell. It is not remarkable for size, but unrivalled for the elegance of design and beauty of the materials used in its construction.

But few iron structures have been hitherto attempted in which the architectural effect has not been more or less marred by the prominence given to large bolted flanges, tie rods, cross braces, or other devices, which, however necessary in a structural point of view, certainly do not add to the beauty of the building. In the design we now lay before our readers, however, there are no signs visible by means of which the whole is put together, not one flange, tie, or bolt of any description being shown in the whole of the building, externally or internally. The castings have all been executed with a degree of care and beauty of finish rarely seen in any large work. Many of the perforated castings employed in this structure are of extreme delicacy and beauty of finish. Among the heaviest are several from three to four tons in weight each, while there are thousands of others not exceeding four to eight ounces.

The conservatory has two floors or crypts, extending entirely beneath it. The lower one receives a supply of fresh air through a perforated stone screen facing the grounds, and forms the cold air chamber. Above this is a second space of equal area, divided from the lower one by a stone floor. The upper space contains a coil of ten pipes of four inches in diameter, the coil being about a hundred feet in circumference, and giving over 1,000 square feet of heating surface. The ceiling of this upper or hot-air chamber is covered by five-inch York flags, laid on rolled iron beams. On the upper surface of these flags the tessellated floor of the conservatory is laid. Ten large slide valves (all connected by a rack and pinion) admit cold air from the chamber below at equidistant parts to the surface of the hot-water pipes. After passing over and among these pipes, the air enters the conservatory through numerous perforated brass panels in such quantities as may be desired. Massive brick piers pass through these floors, and support the sixteen columns on which the upper part of the structure rests.

The conservatory is formed with a large square central area surrounded by a dome. On each side of the square there are bays or transcepts, the entrance to which is beneath three arches, rising to a height of fourteen feet, and resting on columns, of which there are sixteen. The dome is formed of rolled iron ribs, meeting together in the centre and united to a large pendant perforated boss; the ribs (forty in number) are separated by extremely light iron ornamental casting, forming a framework which is glazed with stained glass, which encircles the dome in three distinct bands; exterior to this stained glass is a plate-glass covering, each plate being curved to the true shape of the dome; the plates are each seven feet long, the joints so arranged as to be rendered invisible behind the stained glass panels; the glass is ground on both sides, and embossed in a bold trellis pattern, giving to the whole a most beautiful effect. The employment of ground glass for the dome gives it an apparent solidity when viewed externally from the terrace that surrounds the building, which much increases its architectural beauty. The dome, which is forty feet in height, rests on a series of bold trusses, springing from the sills of the upper windows, and forming a division between them; these trusses are perforated on all sides, and are highly ornamented. The ceiling of the central part surrounding the dome is formed into deep soffits, each filled with elaborately designed perforated gilt panels, with an azure background formed by the flat iron roof above them. In the upper part of the central space there are six windows on each side, each composed of a sheet of ground plate glass, engraved and painted

CONSERVATORY AT DENMARK HILL, CAMBERWELL.

in pale tints. These windows all open by an ingenious contrivance worked by an attendant from the cold-air chamber below, which is sufficiently lofty to admit of ready access.

The iron columns have a spiral groove running around them, in which small spheres are fitted by stringing them on a copper wire giving an effect which simple casting could never accomplish; these spheres are all gilt, and give to the fresh grey tint of the columns a great relief; the capitals are all built up with separate acanthus leaves of very light and elegant form, and are also gilt.

The arches, which rest on these columns, are all double castings, placed back to back, and are most exquisitely moulded in a perforated pattern, through which the light falls in ever-varying clusters of rays as one walks about the conservatory. There are thousands of rosettes on these perforated screens, all cast-separately, and screwed in place, so as to get a bold relief, well undercut, an effect which founding in mass could not give.

The external walls are pierced with large circular-headed windows, glazed with a single sheet of plate-glass, with a small Greek border etched around the edge, and narrow margins of coloured ground glass of a soft grey tint etched in patterns. The walls are entirely encased with polished marble, in pieces so large as to show no joints. A richly-moulded architrave of red Devonshire marble surrounds each window and door, and relieves by its warm colour the spaces between the windows, which are of dark Bardillo marble, against which are placed three-quarter columns of white veined Sicilian marble. The shafts of all twenty-four columns, and the angle pilasters are ten feet in length, each in a single piece, and surmounted by capitals carved in white Carrara marble. Above these is a rich entablature of veined Sicilian marble running over the Bardillo, which is ornamented over each window and door, with a rich incised pattern of Arabesque scroll work gilt in all the sunk part. One bay or transept forms the end of the adjoining drawing-room, having two glass doors. The right-hand bay abuts on a billiard-room, having a central door and two large windows looking into it; and opposite to this are two similar windows, and a central door leading on to a raised terrace, ninety feet in length, paved with squares of black and white marble, and extending all along the garden front of the house. The fourth bay is also divided by three equal arches, in each of which there are mirrors of fourteen feet high by seven feet wide, passing down below the floor line, and thus continuing the pattern of the pavement. The mirrors are silvered by a deposit of pure silver, and are not easily injured like those coated with tin foil and mercury. They are kept warm at the back by a hot-air chamber, which prevents any deposition of moisture on them; they thus, at all times, reflect clearly the whole interior of the building, giving it apparently double its real size. Around the sides of the building are raised spaces for the flowers, having a sort of dwarf screen of polished dove-coloured marble, in which are numerous gilt brass panels for the supply of warm air from the chamber below. In the central space beneath the dome is a large basin, richly moulded in beautifully veined Bardillo marble, with four pedestals of the same material at the angles, which serve to support vases of white marble, containing some numerous plants. Eight similar marble pedestals are also formed in the dove marble screen before named, on which are some choice specimens of Majolica vases containing rare plants. Pendant from the ceiling, are six Majolica flower-baskets containing choice ferns and other drooping foliage. There are also eight suspended Roman lamps in bronze, with lotus leaves forming clusters of flowers in gas jets, and also four other suspended Roman lamps of classical design, giving in all eighty gas burners, by means of which the whole building may at night be brilliantly illuminated; there are also near the drawing-room door a pair of exquisitely chased bronzed candelabra, which on ordinary occasions give sufficient light for walking in the evening. The floor is composed of encaustic tiles and tesserae tastefully arranged in panels of quiet colours (so as not to interfere with the brilliant colours of the flowers). In this design are embodied mosaics representing spring, autumn, summer, and winter, and a fifth near the entrance represents Old Time with the date of the erection of the building on a tablet beneath him; at each of the four angles of the central part are life-size figures of boys executed in biscuit china at Sévres. We are indebted to *Engineering* for our illustration of this fine conservatory.

With reference to the plants with which this structure is shown to be furnished: they are not the most suitable kinds to show off its full beauty. Where arch and column seem to vie with the elegant tapering stems of a tropical forest a comparatively poor effect is furnished by dwarf herbaceous vegetation. No such structures are worth erecting unless they shelter in abundance those superb tropical and sub-tropical plants which contrast so charmingly with the herbaceous and small-leaved forms of cold and temperate countries.

BYE-NOTES ON NILE TREES.

My last visit to Egypt was via Brindisi. I travelled, in November, through Bélgium to Cologne, along the Rhine to Munich, over the Brenner Pass to Verona, and so to Venice; there embarked in an Austrian-Lombardy screw-steamer; landed at Ancona— which, like the rest of Italy, was white with snow; by rail to Brindisi. They were shovelling the snow from the rails in Calabria, within thirty miles of that seaport. I don't remember to have ever felt the cold more than in that journey through sunny Italy. After four-and-a-half days from Brindisi, we disembarked at Alexandria, and drove to a country-house in a large garden in its vicinity. No contrast could be greater or more charming; it was like the enchantment of a fairy scene. A balcony, overshadowed by a large old banyan tree, looked down upon groves of bananas, clumps of date palms, their verdure being contrasted with scarlet summits of Poinsettias six and eight feet in height. Glorious purple Ipomeas were climbing and trailing over fence and arbour; roses and Pelargoniums in rich bloom below.

At Cairo I was most struck by the extended fences of huge cacti, and the fine shady over-arching avenues of the "sont" trees (*Mimosa nilotica*), with their long golden pods. There are some grand old Tamarisks, but the foliage is dull. The date palm (*Phoenix dactylifera*) gives the chief and most characteristic feature to the banks of the Nile, though I must own that, after days of voyaging up stream, it begins to weary with its sameness.

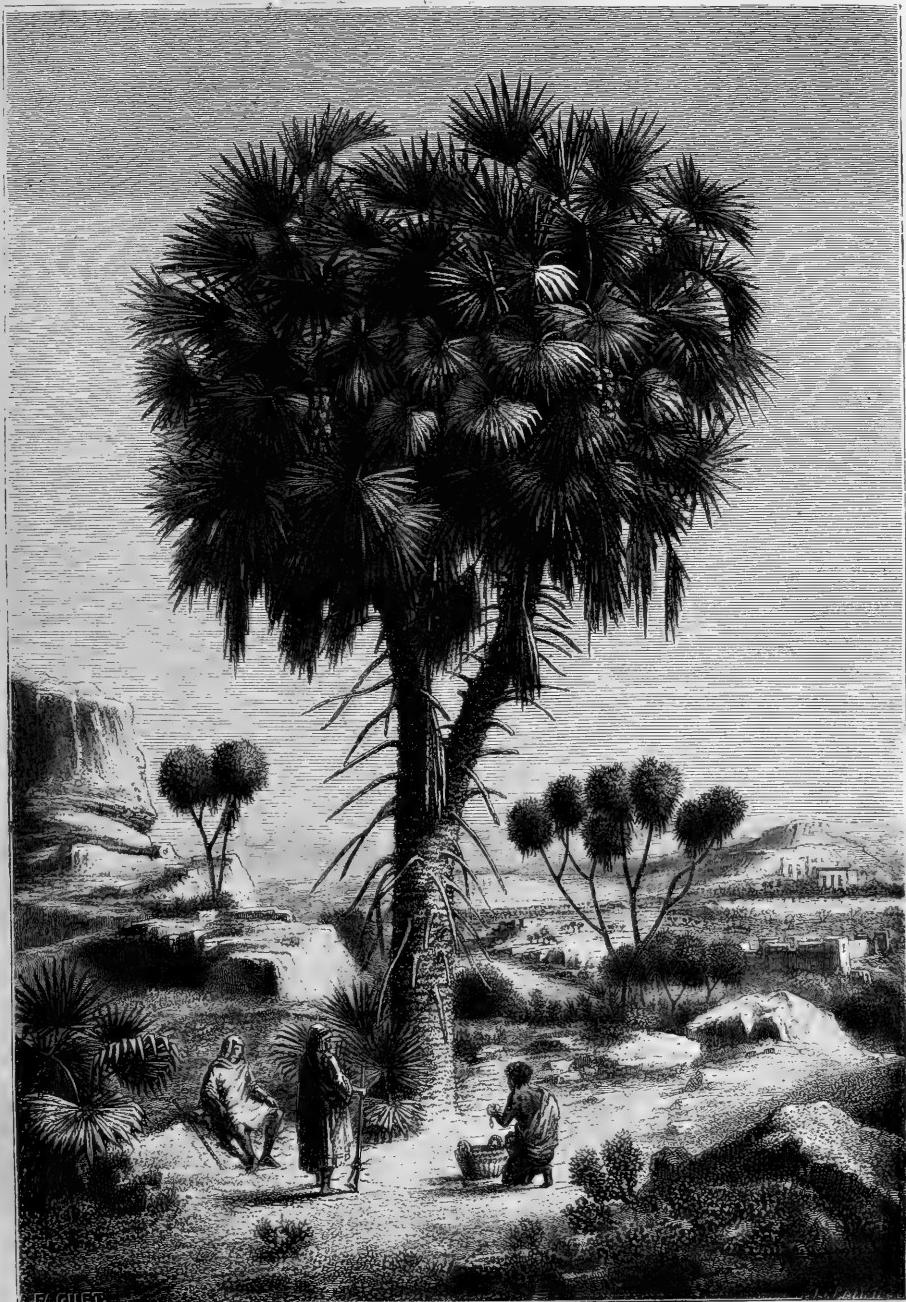

The memory of the varied forms and tints of foliage, the shapes and sizes and branching of the trees, in dear old Richmond Park often came in favourable contrast with the tropical forms I had so much longed to witness. As we entered Upper Egypt, I looked out with a positive longing for the bifurcate stem and the more dwarfed cluster of fan-like terminations of the many dichotomous branches of the second genus of palm, the Dōm, or Doum kind, *Hyphaene*, which marks the warmer latitudes. This genus is diffused, with the exception of the Cape of Good Hope, over the whole of the continent of Africa and parts of Arabia. The trunk is about thirty feet in height, and ringed, and differs essentially from that of most palms in being branched. It is difficult to speak with any degree of certainty of the geographical limits of *H. thebaica*, the subject of our illustration, as its synonymy is somewhat confused; but it is said to grow in Nubia and Abyssinia as well as in Arabia. It is called the gingerbread tree of Egypt. Its stem is frequently three and four times forked or branched in old trees, though when young it is always simple. It is nowhere so abundant as the date palm; its hard, round fruit, with tough, smooth, brownish or yellowish rind, hangs in clusters from the terminal branches. It forms part of the food of the poorer classes in Upper Egypt; the part eaten being the fibrous, mealy husk, which tastes exactly like gingerbread; but its dry, husky character renders it unpalatable. The hard tough wood is used for making various domestic utensils, and rosaries are cut out of the horny seed; hats and mats are made of the leaves. The date palm, however, is unquestionably a grander and more graceful tree; touching which, I may tell you that, after spending a long morning, by special favour, in the gardens of the grand Nile Palace of the Khedive, in which in January all our bedding-out plants were in a blaze of beauty, with endless rare and tropical forms that flourish here in the open air, carefully tended and watered by an army of fellahs, I ventured to express to the head-gardener my surprise that neither Dōm nor date palm were admitted, and suggested the fine effect of a group of the latter reflected from the high (artificial) bank of one of the (artificial) lakes.

"Dame paulin!" replied my conductor, in an accent (northern) of contemptuous surprise; "Ye might as weel talk o' planting cawbages!"

Every cluster of mud huts along the Nile is overshadowed by its grove of *Phoenix dactylifera*, and a tax is levied upon the fellahs for each tree.

There is so much in association of ideas.

R. O.

THE DOUM PALM OF UPPER EGYPT.

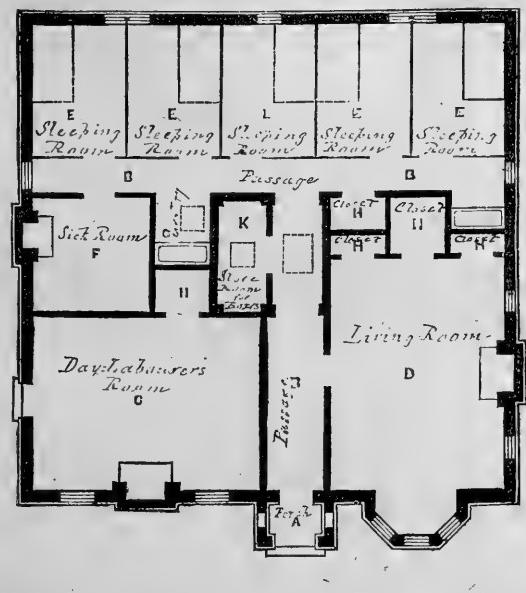

UNDER-GARDENERS' LODGINGS.

Show me the homes of a people, and I will define their character, is a broad way of putting a most important social truth. Man is often the victim than the master of circumstances. Cramped, foul unhealthy homes have their counterparts in the mind, character, and condition of those who live therein. Hence, not only the physical but intellectual and moral importance of better dwellings for all classes of the community. We are glad to note that at last the tide of improvement has risen high enough to threaten to sweep away one of the most detestable of all places called a house—the "boothie" for young men, hidden away out of sight in the back-slums of so many gardens. We sometimes hear complaints of want of intelligence, culture, and polish among young gardeners. Let anyone look into the hole of this pit, whence so many have been dug, and complain no more. Were it not for an inherent nobility in most young gardeners, and the humanising and enabling influence of their pursuits, doubtless the "boothie" system would have trodden out every spark of gentleness or goodness long ere now. An earthen or brick floor, a four-post bedstead—ranged sometimes three or four deep in one room—bare mattress, a table, and a few stools, the whole sufficiently lighted to make darkness visible from a sunless window, without a single convenience for decency, or the slightest attempt to clothe the rawness of its discomfort. Such was, and alas still is, the "boothie" in too many gardens. Who can wonder that it is difficult—impossible—to keep young men at home in such places, or that the village or town public-house, or the street, with its glare of light and its equally glaring vices, draw men out of such dens to a deeper degradation? The most potent receipt for keeping lads or men at home is to surround them with home comforts and conveniences. These are among the most powerful aids to a virtuous life. Place young men in such a house as is here set forth, and the chances are that their conduct will be, or will become, worthy of it. If men accustomed to rove, they will stay in this home at first, probably for the simple reason that they might go further and fare worse in regard to outward comfort. By and bye higher aspirations will spring forth from the order, quiet, cleanliness, and comfort of the place. A process of assimilation will go on. The man will imperceptibly partake of the character of his home; a love of study will be born of its quiet, of culture and refinement of its simple comfort. The three great wants of gardeners at the present day are deeper knowledge, higher worth, more polish; and few things would contribute so much to these as comfortably-arranged rooms for young men, and good houses for head gardeners. One of the most excellent houses for young gardeners we have seen is that in Mr. Peck's gardens at Wimbledon, and of which we give a plan.

D. T. F.

NOTES AND QUESTIONS ON GARDEN STRUCTURES.

Distance of Boiler from Vinery.—What is the greatest distance from the boiler at which I may place a late span-roofed vinery?—CLERICUS.—[A late span-roofed vinery may be placed at any distance from the boiler, varying from ten to one hundred and fifty feet.] You must, however, bear in mind that the greater the distance the larger and more powerful the boiler must be, and the more fuel will of course be consumed. If you can so arrange it, it would be much better to have a boiler of smaller size fixed near the vinery, with an underground stove-hole, and a brick arch turned over it; the boiler to have a small iron chimney.]

Plan of the Young Gardeners' House at Wimbledon Park.

Ventilation of Ice Houses.—Mr. Cunningham's communication on this subject (p. 136) would have been more useful to us if he had been more definite in his details, a trism which all writers on gardening would do well to remember when they endeavour to impart instruction to others. Mr. Cunningham says, "I have never," after the incident which he records, "used straw as a lining between the ice and walls of ice-houses." But he does not say what he uses as a substitute, nor of what his walls are composed, whether of wood, brick, or cement. Our ice-house here is ten feet deep from the ground level, and twelve feet in diameter. It has a conical roof, thatched with heath. The walls are of brick, cemented inside. The first time it was filled there was neither straw nor anything else put between the ice and the wall; and when it was opened, early in the summer, all the ice was gone. The following winter straw was used with a little better success. Six years ago I asked my employer if I might put three iron pipes, two inches and a half in diameter, through the roof, in order to secure a thorough circulation of air, as I consider that to be essential to success—the rabbits at Pitchford Hall, the seat of the late Earl of Liverpool, having taught me this lesson. There was an ice-house there twelve feet cube, the walls of which were built partly of wood and partly of brick. The roof was thatched with straw, and the same material was used as lining between the ice and the walls, as well as to cover the ice with. The rabbits used to make holes through the roof, so that as soon as you got the doors open you could see daylight through them. By this means perfect ventilation was secured, and the house was never empty of ice for six years. The cause of its being empty then, was, because we could not get any ice during one winter with which to fill it. After we had put iron pipes through the roof of our, present house, and had placed some faggot-wood between the straw and wall, ice has kept in it so well that, when we began to fill the house on the 7th of December last, there were two cart-loads of it left. If the wet straw is removed from the top of the ice two or three times during the summer, it will be of advantage to its keeping.—DAVID WALKER, - Dunorlan Gardens, Tunbridge Wells.

Experiment with Glass of Various Colours.—It has long been a question how far colour can influence the growth of plants. On this subject M. P. Bert has addressed an interesting communication to the Academy of Sciences.

Having placed twenty-five kinds of plants in a greenhouse provided with glazed frames of various hues, they watched their progress under the influence of the different lights they received. Milfoil and mullein figured among the plants requiring much sun; violets, &c., among those wanting shade; cactuses and house-leeks represented the thick-leaved classes; there were besides green acetylene plants strongly tinged with red, such as Perilla, and lastly, firs. The individuals of each species were of the same size, having been sown at the same time. The glass of the frames was respectively transparent white, dulled white, black, red, yellow, green, and blue; and the whole greenhouse was shielded from the direct rays of the sun. The observations commenced on the 20th of June; on the 24th various seeds were sown, which all sprang up at the same time in all situations. On the 20th of August the acetylene alone were still alive, though perishing, under the black and green; and as to the rest, the red had proved more hurtful to them than the yellow and blue. The stalks were much taller, but also much weaker under the red; blue seemed to be the colour least detrimental to the plants; their greenness had remained natural, and even deeper than under the yellow. The plants sown on the 24th of June had all died off very quickly under the black and green, later under the red, and had thriven better under the blue than under the yellow. As for the plants under the white glass they all continued to live, though less luxuriantly under the dulled than under the transparent glass.—Galignani.

THE FRUIT GARDEN.

TREATMENT OF WALL TREES.

Some half a century back the wall trees of most of the leading gardens of Britain were superior to what they are at the present time. Where must we now go to find peach-trees with stems measuring from eighteen inches to two feet in girth? True, there are some fine trees still to be found, as, for example, the grand old specimens at Chatsworth, the largest of which last year produced about 1,400 fruits, unsurpassable in quality. If a finely-flavoured peach or nectarine is required—in fact, a superior-flavoured fruit of any kind commend us to an old tree; for, whatever may be the reason, the fact is incontestable, that old trees produce fruit of much finer quality than that which can be procured from young ones. So well aware was the late Duke of Portland of this fact, that in his garden at Welbeck he would not have an old fruit-tree of any kind destroyed until it was quite worn out.

Forty years ago I transplanted at Welbeck dozens of these old trees which had then become barren through penetrating the subsoil; and upon a recent visit to Mr. Tillery, I was glad to see that many of these veteran trees have been removed to the new garden that since that time has been made there. It is astonishing how well large-sized fruit-trees will bear transplanting, and how grateful they are for a fresh supply of good loamy soil.

If taken in time, nothing is so easily renovated as an old fruit-tree; but, as a rule, the pruning, or branch improvement, should precede interference with the roots—that is, we should rectify the branches this season, and transplant the tree, or lift the roots, and add fresh soil, twelve months hence. By reducing the branch action, and concentrating that of the roots upon those retained, we should obtain additional strength of bud, so that when the roots were lifted, that would assist in promoting vigorous root action. From these veterans, of course, we must not expect trees of fine symmetrical proportions, more for sight than service; for though it is not to be denied that "eye sweet" trees do sometimes produce fine crops, we believe the rule will prevail, that those trees which have been the least restrained by training are in the most fruitful and healthy state.

Do not let me be misunderstood—I want system in forming the tree; but I consider the restraint too frequently imposed upon the branches not only unnecessary, but positively injurious. In stone fruits, apricots and peaches especially, the laceration consequent upon the straightening of a branch may, in the first instance, be the parent of "gum," and in future years the inexplicable cause of the sudden collapse of large and healthy branches. This I think much more probable than sunstroke; though sunstroke, acting upon a diseased limb, may be more powerful for evil than if acting upon a perfectly healthy frame.

To prune a tree so as to cover the entire surface of the wall at all times with healthy-bearing wood is the secret of correct management. Tested by this standard, half the trained trees in the country are ill managed; for even in pears, while the top of the tree and the ends of the branches may be full of blossom, the centre will be entirely destitute of fruit.

A few years back, a cottager, who had for a long time been the first wall man in a large establishment, had upon his cottage a splendidly-trained Marie Louise pear. The tree, as an example of training, was perfect to look at, but it bore no fruit. A change of tenants caused the tree to be neglected, and for two seasons it grew innocent of the pruning-knife. In the following spring every branch was found to be a wreath of blossom-buds. The strongest and the very weakest branches were thinned out, and those remaining were tied in in a pendant form, and ever since that tree has stood sponsor for the rent of the house, and for some pounds beyond that amount.

Excessive pruning is worse than no pruning at all, for nature, uncontrolled, will produce fruit; but the unrestrained pruning-knife is too frequently the parent of barrenness. Just the same is it with the peach and other stone fruits. A house or wall has to be replanted, and, to save time, we buy in,

at a high price, two to three seasons' trained trees; and what do we do in the majority of cases? We cut the fine healthy branches back to within a foot or eighteen inches of the bottom—for what? to form what is called a good base to the tree; then, when the tree gets into growth, and the time comes for distending or thinning the young branches, the best shoots, or "robbers," as custom calls them, are rubbed off; and only those of moderate growth are retained. In fact, we want vigour; but we commence with mediocrity, and if the tree attempts the vigorous form, we directly thumb-screw it in some way or other. In this way, it takes something like five or seven years to cover a twelve-foot wall; while, with proper treatment, planting well-prepared trees, a wall of the height named may be covered in a superior manner in three to four years.

To secure healthy, well-rooted trees of moderate growth, plant them, if possible, directly the leaf has fallen, thin out the weak branches, and shorten the others no lower than to where the wood is fully ripe. In this way you will start with a fine covering from its base a radius of three to four feet, and if it is properly planted, and you have the courage to do it, you may increase the radius thereto four feet every season, until the wall is filled. And that is not all; for by such treatment you will insure such vigour as can never be secured by the restraining process. You will obtain, indeed, what our American cousins would term "a live tree," an article very different from the common-place examples which the rule of thumb and pinching processes must give us. I can look upon such trees planted last season, to train which a man uses a ladder, and each tree is capable of bearing several dozens of fruit this season. This is what I call peach culture. To realise the fact that it is the gardener's duty to direct, not to control, nature is the only way in which we can make any marked degree of progress in fruit culture.

W.

NEW PEARS.

I AM always glad to hear that additions have been made to our stock of useful pears, and that if the four new kinds described by M. Baltet, viz., Clapp's Favourite, Poire de l'Assomption, Fondante Thiriot, and Beurré Baltet Père, can be relied upon to retain, at least in some degree, the excellent qualities ascribed to them under the many circumstances of soil and position to which all our cultivated fruits are exposed, in spite of the already formidable list of varieties already in cultivation, we shall find room for them, and welcome them; but this ordeal of latitude, longitude, altitude, soil, and rain, is a trying one, and in my experience many pears with great names and high characters have failed to pass it. It must be remembered that the climate of Troyes presents more favourable circumstances for the full development of the pear than can be found generally in England, and varieties, whose excellence would be admitted when grown in good localities in France, too often fail to maintain the high character sent with them when grown under our cloudy skies. I find a good illustration of my remarks in the list of pears given by M. Baltet, who names, amongst others, several that he esteems unsurpassable in quality—Beurré Diel, Trompette de Jodoigne, Duchesse d'Angoulême. These are large and handsome pears, but, even with the advantage of good wall culture are quite worthless grown at Belvoir. The determination of special soils and localities for particular classes of pears is a work that can only be pursued slowly, as experiments must extend over many years, but it is one that merits attention and consideration. I have observed that fruits, both apples, pears, and plums, and, I may add, apricots, originated in a particular locality seem to have acquired a constitutional fitness for it, and to be less liable to the ailments trees imported from another locality seem prone to. I think we are all bound in our time and generation to do as much as we can towards the increase of good and useful things, and wherever there is a chance of raising a few seedling fruits it should be done. The Rev. Mr. Kingsley's views concerning the selection of the extreme point of a seedling pear, or those shoots that indicate fruitfulness, are of great practical value, and will, if practised, help to shorten the term of watchfulness which, when it lasts eight or nine years, leads to the heart sickness of hope deferred. Belvoir.

WILLIAM INGRAM.

Oranges.—The quantity of these which arrived in Paris for New Year's Day amounted to 254,000 cases. The boxes contained from 320 to 340, but taking the smallest number, we find \$1,280,000 in all, or about forty for each inhabitant.

NEW FRUITS OF 1871.

A.D. 1871 was not a fruitful year, so that our acquisitions in this département are not so numerous or important as usual. Still we have to record several novelties of no mean merit, and such as we may gladly welcome. Grapes, as usual, come most prominently before us. Our indefatigable friend, Mr. Pearson, of Chilwell, presents us with a batch of four, all of considerable promise. In Dr. Hogg we have an improved Duchess of Buccleugh—that is, improved as to size and constitution, the quality being the same, resembling that of the well-known Chasselas Musqué. Abram Bass is fine, firm-flushed, oval black grape, raised from Mrs. Pince's Muscat. Chilwell Alicante resembles the Alicante or Black Tokay, and has a fine rich pleasant flavour which the older variety does not possess. Emperor of Morocco is also a fine-looking black grape, of very rich and pleasant flavour, raised from the Black Morocco. We must here also say just another word for Mr. W. Paul's Waltham Cross, which is one of the noblest-looking of late white grapes yet produced.

Of peaches, Mr. Rivers gives us a batch of novelties, some of which are of great merit. Especially we would note this of Goshawk, one of the richest mid-season peaches grown. Of others we may mention Albatross, Condor, Golden Eagle, Merlin, very rich. Of nectarines, Darwin and Humboldt are two fine acquisitions of the Stanwick class. We may also notice as a mid-season peach of remarkably fine quality the Markly Admirable of Mr. Knight. In apples we have no addition of note; neither in pears is there any very remarkable novelty. We may, however, invite attention to one or two which during the past season have proved of great excellence, viz., Beurré de l'Assomption and Souvenir du Congrès, both having the character of Williams' Bon Chrétien. In cherries we have to add Bigarreau Noir de Schmidt, a fine black heart; and Early Rivers, a very fine, large, fleshy, richly-flavoured sort of great repute. Let us hope that in a propitious season we may have more meritorious novelties to notice.—A. F. B., in "Florist and Pomologist."

PUBLIC GARDENS.

THE THAMES EMBANKMENT.

TURNING down what is called the Albert Embankment stairs to the right, after crossing Westminster Bridge, pedestrians have before them the finest footway in London, but footway only, and scarcely will they have descended the stairs when they will begin to wonder, and wonder the more because they will wonder in vain, why a high brick wall has been built along the whole front of the new hospital just built there, narrowing the embankment, cutting it, as it seems to do, in half, and converting what might have been a high road into a footpath. Why, it may be asked, was not the ground left open to the hospital arcades? Such a concession would have blessed both those who gave it and those who took it. It would have made the embankment a wider way, it would have given passengers something to look at on the land side besides a blank brick wall, and it would have shown off the fine colonnades of the hospital. Were the latter a lunatic asylum there would be some apology for this exclusive wall, which has come so near the water that it has taken inside it the trees planted along the embankment. As it is, we can see no reason for such an arrangement, but that old dog-in-the-manger spirit which induced a Shropshire nobleman of the last generation to spend untold sums in building a wall round his great park high enough to keep out the hunting field. The brick wall in question, however, serves a purpose, for along it are fastened the wooden posts and shabby lamps which light the embankment. Why it is not lit by the proper lanterns, which ought long ago to have been fixed on the handsome dolphin-wreathed pedestals which ornament the outer parapet, is more than we can say or excuse. Opposite Lambeth Palace is a bit of "garden," work which often does not mean much in London, but which means more in the shabbiest square than it means here, upon a work the imperial magnificence of which was thought worthy of a princely name. This garden is fenced by a vile hoarding covered with bill tatters, and by prying between its chinks we may read written in unconscious satire, "Albert Embankment." At another place, some iron railings, no doubt to be in due course coated with "indestructible paint," are in course of erection. Why each patch of garden here and on the Victoria Embankment should be securely fenced in with an unsightly fence, or any fence at all, is not apparent. Foot passengers are practically kept out of them, for who will delay to hunt for the gate? The embankment, which, despite the brick wall of St. Thomas's, began in magnificence opposite Westminster, ends in mire opposite Millbank. A small muddy space is here being reserved for a garden, and another muddy space, which ought to have been so reserved, is "to be let for 80

years." Less ornamental than this "notice board," but quite as significant are the wretched rusty iron stands which protect the trees. One of the trees is badly broken at the top, and if we might make one petition it is that it be substituted by another this very winter. We would further beg that at this season when we hear so much of distress and want of work, a few men be hired to redeem the upper end of the embankment from the filth, the slovenliness, the wilful incompleteness which deface it. Something should, perhaps, be conceded to the *genius loci* of the Surrey side, but even that slatternly goddess must feel ashamed of herself as she sits over piles of paving stones and heaps of rubbish. Something we are ready to concede to her, but something we must demand from the Board of Works. Not that they should do their work; that were hopeless and too much to expect, but that they should not take credit for having done it when they have left it so shamefully undone. If even this be too much to require of them, we can at least say with confidence that, whatever credit they may choose to give themselves, they will not get any from that portion of the public which walks along the Albert Embankment. That this work and its more than match on the other side of the river are noble works, that they were boldly conceived, undertaken with spirit, and finished in their solid and costly parts with ease and success, only makes the present neglect of them the more inexplicable.

SITUATION OF CITY PARKS.

First of all, a public park should be as near as possible to the town; best of all, perhaps, if in the very centre of the town, or, as in the case of some of the old walled towns of Europe, girding it with a circle of green. I hardly think any public gardens of the world contribute more to the health and enjoyment of the adjacent population than those of Frankfort-on-the-Main, which lie all about their homes, and which are planted upon the line of the old fortifications. Even the ill-kept walks upon the ancient walls of Chester and York (in England), by their nearness to the homes of the people, and by the delightful out-look they offer, are among the most cherished promenades I know. But with us, who have no girding walls, and rarely vacant spaces about our commercial centres, these pleasant breathing-places must be pushed into the outskirts of our towns. I say—rarely vacant spaces; but while I write, there occur to me instances of beautiful opportunities neglected, one of which, at least, I will record. The thriving little city of Norwich, in eastern Connecticut, is situated at the confluence of two rivers, which form the Thames. Along either shore of the Yantic and the Shetucket, the houses of the town are picturesquely strewed with patches of white and grey; but between the rivers and the lines of houses, the land rises into a great promontory of hill—toward the east, forming a Salvador-Rosa cliff, shaggy with brush-wood and cedars—towards the south and west, a steep declivity on which the swiftly slanting sward-land is spotted with outcropping ledges; to the north a gradual slope falls easily away to the great plains where lie the bulk of the suburban residences. Within twenty or thirty years the whole upper surface of this central hillock might have been secured for the merest bagatelle, and would have made one of the proudest public promenades imaginable, accessible to all walkers from the south and east, and to all equipages from the north, and offering level plateau for drives that would have commanded the most enchanting of views; but the occasion has gone by; inferior houses hold their uneasy footing on the hill-side, and a gaunt gaol, which is the very apotheosis of ugliness, crowns this picturesque height.

Another little city, that of Hartford, in the neighbour State of Connecticut, has made the most of its opportunities by converting into a charming public garden a weary waste of ground that lay between its railway station and the heart of the city. The opportunity was not large, to be sure, but it was one that needed a keen eye for its development, and the result has shown that commercial thrift may not infrequently take its lesson with profit from the suggestions of a cultivated taste. There is many a growing town having somewhere within its borders such unsuspected aptitude and capability, that only needs an eye to discern it, and the requisite enterprise to develop in the very heart of the population a garden and a public promenade that would become a joy for ever. It must be remembered, furthermore, that it is quite impossible to make such transmutation of waste and unsightly places into an attractive area of garden-land, without increasing enormously the taxable value of all surrounding property. I recall now, in one of our most thriving seaside cities, a great slough of oozy tide-mud of many acres in extent, shut off from the harbour front by a low railway embankment, showing here and there a riotous overgrowth of wild sedges, foul with heaps of garbage, uninverting in every possible way, and yet lying within stone's throw of the centre of the city. Sandy highlands, almost totally unimproved, flank it immediately upon the west—disposed there, as it

would seem, for the very purpose of furnishing easy material for the filling in of the flat below. A few thousands would accomplish this, and judicious planting and outlay would in three years' time establish a charming promenade or garden in the centre of the sea-front of the town, and there is not one of the adjoining pieces of property but would be doubled by the operation. The neglect of such opportunities, whether due to miserable local jealousies or, as often happens, to the short-sightedness and indifference of municipal authorities, is surely not complimentary to our civilization.—*Rural Studies.*

NOTES AND QUESTIONS ON PUBLIC GARDENS.

The Colosseum in Regent's Park.—This, we learn, is to be converted into a site for baths of all kinds. The surplus space of the plot of ground in which it stands is to be laid out as a winter garden, and the block of buildings facing Albany Street will be partly rebuilt, and converted into club chambers.

Enlargement of Victoria Park.—A public meeting, convened by the committee of the Victoria Park Preservation Society, in furtherance of the above-named object, was lately held in the New Town Hall, Hackney; Mr. C. Reed, M.P., in the chair. The chairman said since the rising of Parliament at the end of last session it had seemed to him as if everything they held dear in the way of recreation-grounds were in peril. Within a recent period they had had a struggle with regard to London Fields, Hackney Common, Hackney Downs, and Epping Forest; and only last week it was his duty, as one of the representatives of that borough, to appear before the Conservators of the river Lee to protest against the pollution of those once beautiful waters, to which so many of the inhabitants had been in the habit of resorting for recreation and sport. In the case of Epping Forest the Corporation of London had stepped in to support the cause of the people, and he trusted there would be speedy redress. In the present instance there was no charge to make against any one taking away property. Victoria Park was set apart under an Act of Parliament in the year 1842 for the benefit of the people, only 290 acres being devoted to that purpose, and about 90 acres being reserved with a right of building. This right had been already exercised to a certain extent; a belt of about 30 acres was still left in the most interesting portion of the park, and it was the intention of the Government that that ground should be let on building leases. Well, the Government no doubt felt that it was performing its duty in the matter; but it would be a pity if, when the people of that district had laid their case before the constituted authorities, and, as would perhaps be done ultimately, before Parliament, their voice in reference to their own park was disregarded. The rector of Bethnal Green moved the first resolution, viz., "That this meeting is of opinion that the area of Victoria Park should be enlarged by the addition of the Crown lands reserved for building purposes." He thought the inhabitants of that district should not confine themselves to the present demand, but also ask for the 125 acres, on which were to have been erected the accumulated gasworks of London.—Mr. Holms, M.P., in supporting the resolution, said he was surprised that under all the circumstances they should have to come there to protect only 29 acres of land. He believed that a very good case could be made out before Parliament. The West-end parks and Battersea Park were all maintained at the public expense; and during the last ten years while £59,000 a year on the average had been spent upon them, only £6,600 a year had been spent on the East-end parks. He regretted the use by the Society of the word "enlargement," the object being in reality simply to maintain what the district already possessed. The resolution was carried unanimously.

THE HOUSEHOLD.

THE PARASOL AGARIC. (AGARICUS PROCRERUS.)

THERE are but two other agarics that at all resemble this, and both are edible. One about the same size is *Agaricus rachodes*. It is not generally considered so good in flavour as *A. procerus*. Mrs. Hussey, however, says plainly, "If *Agaricus procerus* is the king of edible funguses, *Agaricus rachodes* is an excellent vice-roy." The other is the *Agaricus excoriatus*, a very much smaller fungus, with a more slender habit, a shorter stem, and no true bulb at the base. This elegant little fungus is also very good eating.

Whenever an agaric, on a long stalk, enlarged at the base, presents a dry cuticle more or less scaly, a darker coloured unboned top, a movable ring, and white gills, it must be *Agaricus procerus*—the parasol agaric, and it may be gathered and eaten without fear. When the whitish flesh of this agaric is bruised it shows a light reddish colour. This is one of the best of the edible fungi, so commonly passed by as useless.

The pileus is fleshy ovate when young, then campanulate, and afterwards expanded and umbo-nate (blunt pointed), from three to seven inches across. Cuticle more or less brown, entire over the umbo, but torn into patches, or scales which become more

and more separated as they approach the margin. Flesh white. Gills unconnected with the stem, fixed to a collar on the pileus surrounding its top. Ring persistent, loose on the stem. Stem six or eight inches high, tapering upwards from a pearl-like bulb at the root, hollow with a loose pith, whitish brown, but more or less variegated with small and close-pressed scales.

The parasol agaric has a very wide range of growth. It is a common fungus, and is in high request all over the Continent.

The following are the opinions of good judges on the merits of the Parasol Agaric as an edible fungus:

"A most excellent mushroom, of a delicate flavour, and it must be considered a most useful species."—M. J. BERKELEY. "Were its excellent qualities better known here, they could not fail to secure it a general reception into our best kitchens, and a frequent place among our side dishes at table."—DR. BADHAM. "If once tried, it must please the most fastidious."—W. G. SMITH.

There can be no question but that, when young and quickly grown, the parasol agaric is a delicious fungus. It has a light and delicate flavour without the heavy richness which belongs to the ordinary field mushroom. The writer has prevailed on many persons to try it; all without exception have liked it, many have thought it quite equal, and some have proclaimed it superior to the common mushroom.

The following are the modes of cooking the Parasol Agaric:

BROILED PROCRUS.—Remove the scales and stalks from the

Parasol Agaric, or Scaly Mushroom (*Agaricus procerus*). Grows in pastures, in autumn; colour, pale brownish buff; diameter, 5 to 12 inches.

agarics, and broil lightly over a clear fire on both sides for a few minutes; arrange them on a dish over fresh-made, well-divided toast; sprinkle with pepper and salt, and put a small piece of butter on each; set before a brisk fire to melt the butter, and serve up quickly. If the cottager would toast his bacon over the broiled mushrooms, the butter would be saved.

AGARICS DELICATELY STEWED.—Remove the stalks and scales from young half-grown agarics, and throw each one as you do so into a basin of fresh water slightly acidulated with the juice of a lemon, or a little good vinegar. When all are prepared, remove them from the water, and put them into a stew-pan with a very small piece of fresh butter. Sprinkle with white pepper and salt; and add a little lemon-juice; cover up closely, and stew for half an hour. Then add a spoonful of flour, with sufficient cream, or cream and milk, until the whole has the thickness of cream. Season to taste, and stew again gently until the agarics are perfectly tender. Remove all the butter from the surface, and serve in a hot dish, garnished with slices of lemon. A little mace, nutmeg, or ketchup may be added; but there are those who think that spice spoils the mushroom flavour.

COTTAGER'S PROCRUS PIE.—Cut fresh agarics in small pieces, and cover the bottom of a pie-dish. Pepper, salt, and place

them on small shreds of fresh bacon, then put in a layer of mashed potatoes, and so fill the dish, layer by layer, with a cover of mashed potatoes for the crust. Bake well for half an hour, and brown before a quick fire.

A LA PROVENCE.—“Steep for two hours in some salt, pepper, and a little garlic; then toss in a small stew-pan over a brisk fire, with parsley chopped, and a little lemon-juice.”—DR. BADHAM.

AGARIC KETCHUP.—Place agarics of as large a size as you can procure, but which are not worm-eaten, layer by layer, in a deep pan, sprinkling each layer as it is put in with a little salt. The next day stir them well up several times, so as to mash and extract their juice. On the third day strain off the liquor, measure, and boil for ten minutes, and then to every pint of the liquor add half an ounce of black pepper, a quarter of an ounce of bruised ginger-root, a blade of mace, a clove or two, and a teaspoonful of mustard-seed. Boil again for half an hour; put in two or three bay-leaves, and set aside till quite cold. Pass through a strainer, and bottle; cork well, and dip the ends in resin. A very little chili vinegar is an improvement, and some add a glass of port wine, or a glass of strong ale to every bottle. Care should be taken that the spice is not added so abundantly as to overpower the true flavour of the agaric. A careful cook will keep back a little of the simple boiled liquor to guard against this danger: a good one will always avoid it. “Doctors weigh their things,” said a capital cook, “but I go by taste.” But then, like poets, good cooks of this order must be born so; they are not to be made.

THE FORESTS OF INDIA.

THESE are beginning to show the effects of the system of conservancy recently adopted. Formerly they were so much neglected that in some districts there were great difficulties in obtaining timber for the public departments; fires, too, did great damage; but in 1863 the Government appointed Mr. Brandis and Dr. Cleghorn to organise a departmental system of conservancy for all India, and the condition of the forests has ever since been constantly and steadily improving. New species of trees are being introduced for acclimation. The gross revenue from the forests has increased from £304,413 in the financial year 1863-64 to the (estimated) amount of £573,220 for the year 1871-72. But the expenses have increased at a greater rate, and are estimated at £451,000 for the year 1871-72, leaving a surplus of only £122,000, the expenditure absorbing four-fifths of the produce. But the object in view is not merely revenue. The forests must be preserved, even if it costs money to keep them in good condition. They are of the utmost importance for the production of timber and fuel, and also for climatic purposes. The systematic supervision of the forests is, however, still in its infancy, as the first set of trained European conservators, under Mr. Brandis, went out only at the end of the year 1869. Nevertheless Parliamentary returns recently issued, show much progress made under the new system of administration. The three principal sorts of trees in the old forests are teak, sal, and deodar. The teak is of peculiar value for shipbuilding and other purposes from the power of the oil to conserve iron. Teak is by far the most valuable of Indian woods. First-class teak for shipbuilding takes seventy or eighty years in coming to maturity; for house building and furniture there is a ready sale for the thinnings in twenty years. Sal wood is used for engineering purposes; for shipbuilding, and for house building. The trees grow very closely together. Planting is not required; the seeds fall viviparous into the ground. This wood takes a long time to season, and it is liable to the attacks of some insects. The best of the deodar timber comes from territory which is not British. Deodar is, in fact, used for sleepers, but it is far too valuable a wood for that purpose. Then there is black wood, of great value for ordnance purposes, for house building, and for carved furniture; it is planted in the same situation as teak, and can be obtained of as large size as teak. Ebony is a wood of great value, and sold by weight. The cinchona cultivation has been a remarkable success on the Nilgirhy hills. It is of extremely rapid growth, and the bark of commerce is obtained at an early age. There are at least 2,000 acres of cinchona on the Nilgirries. It is expected that the leaves may yield a febrifuge for the masses. Of bamboo there are several species; next to the cacao-not, the bamboo is, perhaps, the most valuable wood in India for domestic purposes. It combines toughness and durability with extreme lightness. Rattans grow in great abundance in the forests of Malabar. The rattan is a species of palm, the stem of which runs along the ground for great lengths (eighty feet to hundred feet or more); it is a product of considerable value, and likely

to become a larger article of trade. *Cassia lignea* is an inferior variety of bark, resembling cinnamon in smell and appearance; it is found pretty extensively in Malabar, and some revenue might be derived from it. Wild cinnamon is also found in the forests of Malabar; for all such articles there is a coming demand. There are several woods that produce good bark for tanning. Caoutchouc and gums of similar properties are found largely in Assam. There are several species of gum to be obtained in the forests of India, and dye stuffs; and a very large production of honey and beeswax. The breadfruit tree is grown in gardens. The betel nut is a valuable tree. The casuarina, or beef-wood, is a very useful tree, of rapid growth, and the timber of great hardness. It is quite large enough for building purposes. The wood is very hard, and turns the edge of the axe. It has the peculiar property of durability under water. The satinwood is much used for picture frames and fancy purposes; it resembles the American maple. The Indian dogwood, a small tree of about fifteen feet, is considered remarkably suitable for charcoal for gunpowder purposes. Many other species of wood might be mentioned which will be useful to conserve and propagate—the red cedar and some species of the mahogany family; ironwood, which is practically imperishable, and so forth. The cultivation of wood for fuel is of importance; in the drier parts of India it is so deficient that manure is burnt, and consequently the land is starved and production diminished.

Reports from British Burmah show that, of the total area of 60,000,000 acres, there are 1,534,000 acres of teak-producing forests, and 2,946,000 acres of forest void of teak, besides 26,000,000 acres of low-lying forest land and land occupied by 12,845 towns and villages. The Pegu division is the largest and most important. The average age of a first-class tree of six feet girth in this division is found to be 124 years. Besides teak there are valuable forests of ironwood, catechu, thingan, and other trees. The Oudh report describes the forest establishment as beginning to work pretty fairly. Conservancy has been introduced very gradually into the province, regard being had to the requirements of the population, and their prescriptive rights. It is the minor forest produce that is chiefly affected by such claims. The whole of Coorg proper is stated to be dotted with stately forests. The trees attain their greatest magnitude on the declivities of the Ghâts—a stupendous ridge covered with a rich stratum of mould, in which trees grow to a prodigious size. Bamboo of great excellence are found everywhere. From the North-Western Provinces we have accounts of the plantations of Australian trees at Raneeekhet, which are going on favourably. In some cases there has been wonderful progress; but some of the fruit-trees from England died from the heat on their way up the country. The successful introduction of the rapidly-growing Australian trees is regarded as a matter of the highest importance with a view to the supply of fuel. The Bengal report notices the importance of the Sono forests for the production of the Moogah silk, one of the most profitable occupations of the inhabitants of the Luckimpore district. A full account is given of the teak plantations at Nellamboor, in the Madras Presidency. The trees near the streams run to five feet in girth, with straight cylindrical stems sixty feet to seventy feet in height. The Canara conservator dwells upon “the vast resources of the Bala Ghâts of Canara, with its 1,950 square miles of magnificent forests.” Measurements of trees in the Sherole Forest, above Ghâts, gave from eighty feet to eighty-four feet in height from the ground to the intervention of the first branch, with clear cylindrical stems carrying a girth of nine feet from the ground upwards. In some districts in this province, where forest lands were made over to the Inamdaras, effects of denudation are felt. The people say the rainfall gets less there every year; creeks are silting up, and shoals and bars forming at mouths of rivers. Since the forests were cleared along the ghâts, nothing checks the rush of water down the hills; it no longer soaks into the ground. The Sindh forests comprise 317,245 acres; the two remaining districts—Berar and Mysore—are administered for native States. The conservator of Berar, referring to the importance of caring for the humbler trees of the coppice, states that it is certain that, from whatever cause, the rainfall of Berar is not so copious as it was a few generations ago. The Mysore conservator tells of the great forests of the Western Ghâts, with trees of clear stem of eighty feet to one hundred feet to the first branch. He gives some account of the sandal-wood. The tree attains maturity in about twenty-five years, and its girth then varies from eighteen to forty inches. The best parts are used for ornamental articles. The roots and chips, which are richest in oils, go to the still, and are the basis of many scents. It is burnt by rich natives at the burial of relatives. The Province is divided into twenty-four sandal districts under managers, who mark and collect the wood. It may be added that the Forest Department in India covers an area greater than that of the British Isles.—Condensed from “Times.”

THE AMATEURS' REMEMBRANCE.*

In-door Plant Department.—The conservatory will now be daily receiving fresh floral life from the forcing pit, and to the latter constant successional supplies must be introduced. Shelves edged gracefully with Isoplexis or with *Lycopodium denticulatum*, will now be gay with early tulips, lily of the valley, cyclamens, poinsettias, primroses, and the earliest cinerarias; while tastefully dispersed amongst the more permanent occupants of the house will be azaleas, kalmias, rhododendrons, heaths, and similar flowering shrubs. These with camellias, some of the earlier acacias, tea-scented roses, and the powerfully sweet-scented *Lucilia gratissima*, will maintain an amount of enjoyment greater by far than that derivable from much more brilliant displays made later in the year. Keep up a night temperature of some 45 degrees, allowing a rise of ten degrees or more during the day. At this season, more than any other perhaps, the value of tree ferns, palms, the nobler types of succulent plants, dracaenas, &c., is felt. They give us in the midst of our dreary winter all the ravishing exuberance of lovely forms that are seen in the fairest parts of tropical countries. In a conservatory now filled with these plants a few kinds of flower and berry bearing subjects go as far as thrice the amount in one of the very commonly seen conservatories naked of all beauty of form.

In-door Fruit Department.—Succession pine-apples must be kept growing steadily; they must therefore be supplied with sufficient heat and moisture to keep them in that condition, and the amount of air-circulation must be increased as the days lengthen. As they will soon require repotting, have soil and pots ready in for that purpose. Pines finishing off fruit should be kept all but dry; but such as have fruit still swelling should have a good soaking of tepid, clear manure at the root, as often as they appear to require it. Vines in houses from which the fruit has been cut, should now be pruned and cleaned, preparatory to their being again started into growth. As light increases early vines may be indulged with a little more heat than would have been advisable a week or two back.—Cucumbers sown for early spring use in a hotbed or moist warm stove. Temperature from 65 degrees to 80 degrees.—Seakale, rhubarb, and asparagus, place in heat according to the succession required.—Potatoes started in pots or boxes plant out into frames or pits near the glass on a gentle bottom heat, always giving them abundance of air when there is no danger from frosts.—Radishes and small salads may be sown between the rows.—Mint, tarragon, &c., may be easily supplied from pots placed on shelves along with French beans.

Flower Garden and Shrubberies.—While the weather is favourable all alterations in the form of ground work should be finished with as much expedition as possible. New roses may still be made and planted, care being taken to put stakes to standards so as to keep them from wind-waving. Tender sorts should be examined, and where the protection given them seems insufficient, or has been displaced, fresh, dry coverings must be supplied. Fern, laurel, or spruce fir branches make excellent protections, and these are in general pleasurable enough about most gardens. In most places, however, this period is one of rest in this department. In-doors, nevertheless, much will have to be done in the selection and ordering of seeds, &c., for spring and summer sowing.

Hardy Fruit and Kitchen Garden.—Pruning and nailing of wall trees must now be pushed forward with activity, as must also be the pruning of espaliers and pyramids and dwarfs in borders. Trees in orchards should likewise have their generally overcrowded heads thinned out a little, removing in the operation all ill-placed branches, or such as cross one another. Defter pruning gooseberries and currants until a little later in the season.

In the kitchen garden, where cabbages have been loosened by frosts, go over them and make them firm with the foot, afterwards earthing them up a little with the draw hoe. A row or two of early peas may be put in on a sheltered border, but care must be taken to keep them from being injured by mice. A few mazagan beans may also be put in, and a pinch of radishes and horn carrots may likewise be tried in some warm corner. Clear off crops now done with, and trench and dig the ground they occupy in order to be ready for other crops.

Labels.—I want to give a little more information on the subject of labels than is given at page 156 of your last number. The cast-iron labels for herbaceous plants there recommended were largely introduced into the Botanic Garden, Regent's Park, years ago by yourself, I believe, Mr. Conductor. I visited these gardens recently, and thought I would just look at the labels. I found some of the oldest, done seven or eight years ago, and noted their dark, dim colour, and general indistinctness. I rubbed them with my wet finger, and they brightened a little; I rubbed again and again, and they became as bright as new. I then looked out for the very dimmest I could find. This I rubbed, touched the soil with my finger, rubbed again, and it became bright and perfectly legible. Therefore, if, instead of painting afresh every six years, they are simply well scrubbed, and newly varnished, they will want nothing else. A great point in regard to these labels is their comparative invisibility. A large bed may have two hundred of them on it, and yet at twenty yards distance you will scarcely suspect the presence of one. On the contrary, white ones with black letters are very conspicuous. I wish some good firm would set to work, and get up a stock of these labels; they ought to be obtainable at from ten to twelve shillings per hundredweight. Anyone interested in this matter may readily see these labels just as I rubbed them in the herbaceous garden near the head of the lake in the Botanic Garden, Regent's Park.—A. D.

* Complete general calendars, written by some of the most able gardeners in the country, are published in THE GARDEN in the first issue in each month.

Vegetation on Houses.—We inspected recently several hundreds of villas and mansions that had cost from £2,000 to £10,000 each, and had been built within the last eight or ten years, near a growing city. The architecture of these houses was very varied; but our conclusion was that they were all staring and ugly until they were clothed with creepers, and fringed with foliage, and that they were pretty in proportion as they were well planted and covered with vegetation. If we invite the imagination to separate the picturesque old square-built cottage from its adornments, its patches of house-leek and moss on the roof, its vine-covered wall stained by age, its jessamine and honeysuckle, and rustic porch with skeps of bees close by—what a very ugly building we behold: four plain walls, capped with a red-tiled roof, more frightful than a red nightcap.

COVENT GARDEN MARKET.—January 13th.

Flowers.—These consist of *Acacias*; *Azaleas*, both cut and in the form of small plants; *Begonias*; *Callas*; *Camellias*; *Cinerarias*; grand example of *Lily of the Valley*; *Coronilla*; *Cyclamens* in pots in excellent condition; *Deutzias*; *Heaths*; *Euphorbia jacquinifolia*; *Hyacinths*; *Tulips*; *Genista*; *Geraniums*, of various sorts, including those with scented leaves, a class now too much neglected; *Christmas Roses*; *Mignonette*; *Poinsettias*; *Primroses*, both wild and Chinese; a few cut *Roses* and berry-bearing plants, such as *Ardisia* and *Solanum*.

Prices of Fruit.—Apples, per half sieve, 2s. to 5s.—Cobs, per 100 lbs., 6s. to 6s.—Fiberts, per lb., 8s. to 10d.—Grapes, per lb., 2s. 6d. to 6s.—Lemons, per 100, 7s. to 10s.—Spanish Water Melons, each, 2s. to 5s.—Oranges, per 100, 6s. to 10s.—Pears, per dozen, 3s. to 6s.—Pine-apples, per lb., 4s. to 8s.—Pomegranates, each, 4d. to 8d.

Prices of Vegetables.—Artichokes, green, each, 6d. to 8d.—Asparagus, per 100 lbs., to 10s.—Beet, per dozen, 1s. to 2s.—Broccoli, purple, per bundle, 10d. to 1s. 3d.—Brussels Sprouts, per half sieve, 2s. to 3s.—Cabbages, per dozen, 10d. to 1s. 3d.—Capucinas, per 100, 1s. 6d. to 2s.—Carrots, per bunch, 5d. to 7d.—Californian, per dozen, 2s. to 6s.—Celery, per bundle, 1s. to 2s.—Chilis, per 100, 1s. 6d. to 2s.—Cucumbers, each, 1s. to 2s.—French Beans, new, per 100, 3s. to 4s.—Herbs, per bunch, 2d. to 4d.—Horseradish, per bunch, 3s. to 5s.—Leeks, per bunch, 2d. to 4d.—Lettuces, per score, 1s. 6d. to 2s.—Mushrooms, per potte, 1s. to 2s. 6d.—Onions, per bunch, 4d. to 9d.—Parsley, per bunch, 2d. to 4d.—Radishes, per bunch, 2d.—Rhubarb, per bundle, 1s. 6d. to 2s.—Salsify, per bundle, 9d. to 1s. 3d.—Scorzonera, per bundle, 9d. to 1s. 3d.—Seakale, per punnet, 1s. 6d. to 2s. 6d.—Shallots, per lb., 8d.—Spinach, per bushel, 3s. to 4s.—Tomatoes, per small punnet, 3d. to 6d.—Turnips, per bunch, 3d. to 6d.

ANSWERS TO CORRESPONDENTS.

P. J. N.—1. Fernery at not less from 55 degrees to 60 degrees, as it contains tender species; 2. The flower-forcing house at from 60 degrees to 65 degrees, and from six to ten degrees higher with sun-heat.

R. W. PRINCE.—1. Better leave them till April; 2. Wilkie's Composition; 3. being of general interest will be answered in our Fruit Department next week.

R. A. F.—We know of no remedy except presenting the dog to some of your friends.

C. J. (Wales)—Mr. Baker has done much to clear up the nomenclature of lilies in the *Gardeners' Chronicle*, and in the Journal of the Linnean Society. There is no real difference between the varieties you name.

WASHINGTON, T.—Next week.

GEORGE MALTBY.—*"Mrs. Loudon's Amateur Gardener's Calendar."*

J. J. WHEELER.—The "Grizzly Giant" is a specimen of *Sequia (Wellingtonia) gigantea*. You call "Taxodium" is also a *Sequoia*, and old tree of both species have very thick bark.

W. STEVENS.—Where lies the difficulty? The bridge is certainly made without nails.

C. C. (Bromley).—The American fruit-preserving jars are not, so far as we are aware, sold in this country. They might easily be imported.

W. E. D.—The Prunella blanda sent were large in size and richly coloured.

J. H. C.—The fullest account of the subject is in the book you mention.

J. S. FARRELL.—"The Wild Garden" published by John Murray.

G. M. (Dublin).—Any respectable nurseryman.

Part I. of THE GARDEN, containing 6 Numbers and upwards of 80 Illustrations and Plans, is now ready; price 2s., and may be had from all booksellers and newsagents, and at the railway stalls. Post free from the Office, send flat between boards, 2s. 6d.

Readers who may find it difficult to procure the numbers regularly through the newsagents or booksellers, may have them sent direct from the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 6s. for a quarter, payable in advance. THE GARDEN is sent to subscribers by Friday evening's post. All the numbers of THE GARDEN may be obtained from the office, and through all booksellers and newsagents.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER.

"This is an art

Which does mend nature : change it rather ; but
THE ART ITSELF IS NATURE."—Shakespeare.

THE IN-DOOR GARDEN.

CONSERVATORIES IN THE NATURAL STYLE.

BY EDOUARD ANDRÉ.

ALTHOUGH considerable progress has been made during the last few years in the art of grouping plants in the open air in harmony with their natural affinities, the same cannot be said of their disposition under glass. In England more especially, where amateur gardening is so highly developed, and where more attention is concentrated upon the beauty of individual plants than general effect, next to nothing has been done towards developing a more picturesque style in conservatories. Even our largest establishments leave much to be desired in this respect. Of course, in a mercantile or a small private establishment where the plants are either awaiting sale or where they are frequently removed, they will be arranged for convenience, like the bottles in a chemist's shop. But it is surprising that in planting the noble glass palaces of the rich, such as we find at Sion House, or spacious palm houses, like that of Kew, so little regard has been paid to general effect by their originators.

The cause is simply this, that practical cultivation alone has been considered in England, and in all other European countries, and that the knowledge of plants has hitherto been limited to experimental culture. Gardeners have ignored the teachings of plant distribution in so far as it relates to their natural characteristics and the effects resulting therefrom. Information on this subject can only be gained by studying the narratives of travellers, and these unfortunately are often incomplete and uninteresting on this point.

To supply in some measure this defect, we shall attempt to show how a winter garden, in the picturesque style should be treated. Before doing so, however, we should mention that there are some notable exceptions to the monotonous repetitions which we so heartily deplore. In Mr. Llewellyn's garden at Penllergare, in Wales, might have been seen a few years ago an orchid-house aquarium where these lovely denizens of the tropics were planted in the admirable disorder which they present in their native forests. True, it was only on a small scale, but the effect produced was most pleasing. Again, at Paris, the Gardens of Accimilisation in the Bois de Boulogne possess a large and beautiful house, which is designed and planted in the most attractive manner, representing a tropical scene, terminated by a background of rockwork with a cascade falling into a pool at the base and continued onwards in a rivulet meandering through a valley of Selaginellas.

There are also other places known to us, though too few in number, where there are plants of sufficient development to permit of similar disposition, and which might form the main features of such a tropical semi-wild garden as we have in view. There would be little difficulty in thus beautifying the Palm House at Kew, the large Pavilion of the Museum at Paris, the Horticultural Society's fine conservatory at South Kensington, a portion of the Crystal Palace at Sydenham, the large houses at Sion and Chatsworth &c. When in Belgium last year we visited the seat of M. Varocqué, at Mariemont, where a new winter garden, between fifty and sixty feet high, had been erected on the site of an old orangery, in which a Belgian landscape architect of some note (M. Fuchs) had essayed to introduce the style that we advocate. Magnificent palms, tree ferns, cycads, &c., formed the principal features in this splendid building, with an undulating carpet of Selaginellas beneath them. Immediately facing the grand entrance door was an artistic

group of rockwork flanked by a water basin, and planted with evident care. But, in our opinion, the result was not commensurate with the pains bestowed. The walks are too winding, the surface too uneven; the rockery too imposing to appear natural, and the plantations confused, the sides being naked and the centre excessively dense. The artist aimed at the picturesquesque, but he has failed to produce it in consequence of too great profusion, to the detriment of the general effect and the loss of harmony in the details. We quote this example to show that it is easy to err in carrying out the best of plans, and that exaggeration in the intended 'natural style' is more to be deprecated than crowding in the inevitable uniformity of houses with stages and benches.

Even in winter gardens where the aim has been to produce picturesquesque effect, there is always something in the structure to remind us of the artificial surroundings. Thus, walks are indispensable, and they should be of sufficient breadth to admit of free and agreeable promenading. To try to imitate the forests of Brazil by compelling the spectator to scramble over the rotten remains of trunks of fallen trees, rough stones, and withered fern fronds, would be the height of absurdity. And those interminable winding tortuous walks are equally opposed to good taste, with the rectangular paths which remind us of the system and order of a purely botanical garden. There is thus a *mezzo-termine*, a happy medium, to be studied; and the *nil nimis* of Horace, which neither admits of too much nor too little—the great rule that reigns supreme in all matters of taste and judgment—is equally applicable in the case of our ideal garden.

An outer circular or slightly devious walk near the well-clothed side-walls or lights should surround the central area, where the eye rests upon choice specimens standing out distinctly upon a carpeting of *Selaginella denticulata*, trailing *Commelinaceae*, *Lippia repens*, *Spergula pilifera*, and other plants which readily form a close and compact verdure. To be brief, the space between the walks and the walls should be filled with dense masses of foliage effectually concealing the stems of the plants, and rising gradually from the walk outwards; and the centre should show isolated trees and little groups upon an open lawn of creeping plants.

Such is the arrangement indicated upon the plan (see p. 184), though the detached specimens must not be planted indiscriminately in the central area, which is surrounded and intersected by the walks. They should be grouped in combinations or planted singly, according to size and foliage, and in such a way that the view between their trunks is uninterrupted; and at the same time their heads should harmonise together in colouring and outline.

Instead of undulating the surface in an infinity of insignificant hillocks, as in M. Varocqué's winter garden, we recommend limiting it to two intercepting dells. A longitudinal one from the rockery, terminated by a bower, under which are placed a table and seats, and ending, at the side entrance, in a single hollow, of which the pool or basin is the lowest point. From this pool to the flower-bed No. 94, the ground rises slightly, and the cross walk curves towards the middle in agreement with the lower ground. The boundary walk is of the same level throughout, except towards the rockery, where it rises and terminates in four or five rustic stone steps leading to the alcove. The beds Nos. 94, 123, and 167, should be elevated about two feet above the walk; and each of the isolated trees should be planted on a scarcely perceptible mound of earth, with the exception of the groups on either side of the rockwork, which are on an abrupt slope, and the large clump on each side of the bed No. 94, which should be raised about nine inches above the walk and gradually sloped off.

It now remains for us to enter into the planting, which is certainly the most important part of a winter garden. This may be considered from several points of view, according to the class of house, whether cold, temperate, or hot, or for orchids or an aquarium. For the present we will content ourselves with treating of a warm-temperate winter garden with a mean temperature of from 65° to 68° Fahr., in which we could place palms and similar house plants, that would thrive all the better for the increased warmth.

We shall take it for granted that, previous to planting, due

care has been given to the drainage and the composition and preparation of the soil. As bottom heat is the main thing to produce luxuriant vegetation in plants, we will assume, that the hot-water pipes are properly arranged and covered over with flag-stones to prevent the plants on the walls from being scorched, instead of being around the outside, and exposed, as usually is the case. As we consider the question of foliage-clothed walls of paramount importance we must be explicit. If uncovered pipes are considered absolutely essential along the base of the walls, a brick or other partition of some sort should be placed between them and the plants, to prevent too great an accession of direct heat from the pipes. But a still better method is to conduct the heat through underground brick channels to points with open gratings in the walks to allow the heat to rise. The soil, well drained at the bottom, and crossed here and there by the pipes we have mentioned, will materially induce the luxuriant vegetation we so much desire around the walls of the house. The middle will have less need of bottom heat. A good drainage of broken bricks and mortar rubbish will suffice for the subsoil, leaving a depth of about three feet from the mould intended for the plants. Two drains running below this through the house, with an outlet outside, will carry off the surplus water. The composition of the soil may be varied according to the class of plants it is intended for. But, as a general rule, for strong growing plants and large palms it will be found advantageous to prepare the mass in the following manner:—Upon the layer of broken bricks and mortar rubbish a layer of reversed turfs about eighteen inches thick, should be placed, and upon that a second formed of—

Argillaceous earth	3 parts.
Ordinary garden soil	3 "
River, or white sand	2 "
Coarse pieces of earth and brickbats	1 "
Leaf mould	1 "

10

Mix this well together and apply it about a foot thick. Then for the surface add a layer about five or six inches thick of peat, loam, and leaf-mould from hedgerows, or rotten willow, oak, or chestnut trunks, if attainable, with a tenth part of sand. The peat should be slightly broken up except just at the top, and the roots left in it. Prepared in this way, it will be ready to receive the Selaginella, which will thrive admirably in it and speedily clothe it with verdure.

It will be understood that these three layers, forming a total thickness of three feet, will not be of uniform thickness all through the house, because the surface will be undulated. The measurement of one yard is merely given as a basis or unit, for the total depth of subsoil in different parts of the house will vary, having, for instance, a depth of only eighteen inches near the basin in the centre of the little lawn, and from four to five feet for the clumps abutting on the flower-bed No. 94. But the top-dressing will be equal all over.

The majority of large tropical plants can be grown in such a compost. And those which may require special treatment may be potted in suitable soil and plunged; the pots being plunged deep enough to conceal them. Allow the Selaginella to spread over their surface. Liquid manure, if used in moderation and judgment, will accelerate the growth of most plants, including ferns. So much for the preparations for planting. But the key of the question, the secret of success, depends above all upon the choice and grouping of the plants. This selection may vary to infinity, such are the riches of exotic flowers at our command. It is difficult to lay down rules on the mode of arranging plants according to the colour and character of their foliage. We may, however, remark that in houses, no matter how splendidly constructed, the effects of uniformity are bad, and that masses of one species or of one genus of plants should be avoided. The harmony and grandeur of unity in composition, attained with difficulty even in large parks, is here impossible. The object to be sought, then, is contrast in the foliage and habit of the plants employed. Two species of massive foliage, for example, should not stand side by side, such as a Musa and a Ravenala, or a Coccoloba pubescens and a Theophrasta. But a large tuft of a Streitizia beneath the shade of a Cocos plumosa is very effective, and a fine con-

trast is presented to the eye by backing up the grand foliage and yellow spikes of Hedychium Gardnerianum with clumps of ferns, bamboos, or feathery conifers. The rigid foliage of rhododendrons and camellias should be excluded, these beautiful plants being reserved for a separate house, where they will better display their charms in a collection.

In dense masses of foliage, like those adjoining the rockery in our plan, the arrangement should be in gradual rising ranks, thick, heavy foliage forming the basis, surmounted by lighter and more graceful forms of palms and tree ferns, whose slender plumed columns break through the sombre undergrowth.

Limits the use of "flowers" to the borders and special beds, with the exception of herbs and there one on the rockwork, beyond those belonging to the plants themselves. We mean by "flowers" such plants as are grown in pots in special houses and taken to the winter garden for temporary decoration, as—primulas, cyclamen, Van Thol tulips, hyacinths, heaths, crocuses, &c.

The side walls, or sashes, should be provided with wire trellis-work, or wooden lattice-work against a dead wall, to support climbing plants all round the house. For covering the surface of the soil nothing is better than Selaginella tenuiculata; and this should be planted, or re-planted in autumn, or in spring, as the dry heat of summer is unfavourable to the success of this operation. Small fragments, about three inches long, planted four or five inches apart, will soon cover the ground. For edging the walks use slight castings in imitation of rustic

Section of a Conservatory arranged in the Natural Style.

woodwork, or archlets such as may be found in the squares of Paris. These will keep the border even, and prevent the feet of visitors from straying upon them and the loose earth from crumbling away. Above all a good system of shading must be ensured to protect the plants from the direct rays of the sun in summer.

The paths may be formed of fine gravel, or, better still, asphalted or paved. The construction of the rockery should be of the simplest kind, composed of a few stones naturally disposed and projecting slightly from the earth so as to be discovered rather than seen. Monumental rockwork should be avoided, and, above all, reject the so-called pretty stones. Geological or mineralogical toys may be all very well in the cabinets of the learned, but they are altogether out of place in a garden where the object is to reproduce natural beauties in their native simplicity. If a small pond be added to the rock-work it should neither be absolutely round nor sinuous. The golden rule—simplicity without excess—should everywhere prevail.

In order to secure a warm, humid atmosphere, so essential to the well-being of plants, we recommend having the pipe that feeds the cascade and replenishes the basins made so as to pass through the boiler, which will sufficiently heat the water in its transit to cause it to give off a portion by evaporation when discharged. In this way the atmosphere will be thoroughly saturated with moisture, adding thereby greatly

to the healthy appearance of the plants. We would direct especial attention to this contrivance for ensuring a congenial atmosphere.

As regards choice of plants, as has already been observed, it may be varied indefinitely. But instead of treating of this subject under the numerous aspects it presents we prefer giving the arrangement we suggest for the house represented in the accompanying plan. This arrangement is, of course, applicable to a far larger structure than the one under consideration. But we have selected this example because it comes within the means of a greater number of amateurs. Furthermore our design is open to every conceivable modification. We may add, too, that the outlay may be reduced by substituting less costly plants for some to be enumerated.

DISTRIBUTION OF THE PLANTS.

Perennial climbing plants for placing alongside of walls, or for covering supporting columns, may consist of,—

- (1) Aristolochia cordifolia, which is very vigorous, and has large

blue flowers with yellow centre; (60) Thunbergia laurifolia; (62) Passiflora Buchananii, and (63) P. marmorea, two pretty, vigorous species; (65) Bougainvillea lateritia, fine red bracts; (68) Aristolochia gigas, a very large striped flower, resembling a pilot's cap; (71) Bignonia incarnata, flowers tubular and flesh-coloured; (72) Tropaeolum Lobbianum; (74) Allamanda nobilis; (77) Clerodendron Thomsonae; (80) Cissus discolor.

If we enter the principal doorway of the house and bear to the left, near No. 1, we shall come to the outer border of which we have spoken, which should be filled mainly with strong-growing foliage plants. Nothing will prevent these from being increased and renewed as often as we please. These plants being grouped according to size, the larger ones behind may consist of the following species, viz.:—

Anomum grana-paradisi, Andropogon squarrosum, Panicum plicatum, Fuchsias, Aspidistra, Dracaenæ, Begonias, Coleusæ, Cyperus, Eugenia, various free growing tufted Ferns, Ficus elastica, F. rubiginosa, Aralia and Oropanax, Hedychium coronarium, and Gard-

View in a Conservatory Planted in the Natural Style.

leaves and enormous flowers; (3) Thunbergia Harrisii, moderately vigorous, flowers numerous and delicate; (5) Argyreia argentea, leaves oval and silvery; (7) Ipomoea Horsfallia; (9) Tecoma stans, which has pinnae leaves and pretty flowers; (12 and 13) Plumbago capensis, a fine species, having numerous clusters of azure flowers; (17) Hoya carnosa; (19) Smilax marmorata, leaves oblong and marbled with white; (21) S. macrophylla maculata; (23 and 25) S. marmorata; (27) Hoya imperialis, a vigorous kind, bearing corymbs of rich brown flowers; (28) Stephanotis floribunda; (30) Passiflora Decaisneana, a species with large foliage, and large rose and violet flowers; (31) Quisqualis indica, a free blooming scarlet-flowered plant; (33) Tacsonia Van Volxemii, a kind with long, pendulous, splendid rosy flowers; (36) Aristolochia leuconeura, cordate leaves with white veins; (37) Hoxcentris myrsinoides, flowers variegated salmon; (41) Centrostemma multiflorum, a charming melastomaceous plant; (44) Passiflora carminea; (45) Aristolochia clypeata, new species, with finely marked flowers; (49) Tacsonia mollissima, flowers rose-coloured, long and tubular; (53) Quisqualis pubescens, magnificent orange-red flowers; (54) Passiflora trifasciata, trilobate leaves, stained with red; (58) Meyenia erecta, charming

nerianum, Hibiscus rosa-sinensis, Heterocentrum, Salvias (to be frequently renewed), Haematoxylon campechianum, Imantophyllum Aitoni, Lantanas (various), Ageratum celestium, Senecio platani-folia, Laurus Camphora, Melastomaceæ (various), Plumbea coccinea, Pogostemon Patchouli, Poinsettia pulcherrima, Rogieras, Sparmannia africana, Xylophylla latifolia, Abutilons, Allamanda nerifolia, Piper and Macropipers, Begonia Sedenii, Centradenia grandifolia, Francieas, Gardenias, Hebeclinium ianthinum, Siphocampylus (bicolor and fulgens), Iresine Herbsti, Amorphophallus, Hibiscus liliiflorus, and Marantas, &c.

Above this groundwork of foliage and flowers the following species, with taller stems and stronger habits, may rise:—

- | | | |
|--------------------------------|------------------------------|---------------------------------|
| 2. Ma paradisea | 35. Cyathæ modularis | 59. Freycinetia |
| 4. Oropanax dactylo-
folius | 37. Cyathæ pendula | 61. Oropanax plati-
folium |
| 6. Alsophila anstralis | 39. Artocarpus incisa | 63. Scindopodium pul-
chrum |
| 10. Stannmannia australis | 40. Musa violacea | 65. Astrapea Wallichii |
| 15. Anthurium aculea-
num | 42. Hedychium cocci-
neum | 67. Anthurium regale |
| 16. Rhopalæa Organensis | 43. Cladodiscus palmata | 70. Cereus mexicanus |
| 20. Saurauja sarapi-
gensis | 46. Gibotovia regale | 73. Theophrasta impe-
rialis |
| 22. Dracæna arborea | 47. Castilleja elatista | |
| | 48. Anthurium cordatum | |

PUBLIC GARDENS.

HAMPSTEAD HEATH.

SATURDAY last was the day appointed by the members of the Metropolitan Board of Works for taking formal possession of Hampstead Heath, and for dedicating the same to the public. Thus, after years of agitation, an arrangement has at last been effected by which the great bulk of the Heath—that is to say, land consisting of the upper and lower Heath proper, to the extent of some 225 acres—has been secured to the public for ever at a total cost to the metropolis of £45,000. The wet and unpropitious weather prevented anything like festivity; but Colonel Hogg, M.P., chairman of the Board of Works, and other gentlemen, were invited by the Hampstead Vestry to a *déjeuner* at "Jack Straw's Castle." The Rev. Charlton Lane presided. It was stated that, by the liberality of the Lord of the Manor, the "Lovers' Walk" and other classic localities, supposed to have been surrendered to bricks and mortar, were really given up to the public, which it was said, was to have the Heath for enjoyment as it is, and not as a London park. Thus, bit by bit have we secured our famous, healthy, charming, and invigorating Heath. Let us, therefore, be grateful. We may build fine squares by the score; but we can never create such another landscape, in close view of London, as was looked over by the authorities on Saturday from the windows of "Jack Straw's Castle." There are to be no more disputes concerning this Heath; its broad and breezy upland is safe henceforth as the playground of the metropolis, inspiring health into thousands upon thousands, offering pleasure upon every holiday, spreading its wide and unsophisticated landscapes up hill and down dale—at all events, from the railway-station to the famous flagstaff—and constituting to the whole north and north-west of London, frightfully and hideously overbuilt as it is, what Epping Forest, which is the next of our relics to be saved, is to the denizens of the east. We are glad to learn that it is not contemplated to convert the Heath into an ordinary London park, with pathways of gravel, parterres of flowers, mazes, and, worse than all, fences; it is to remain as open and as wild as a thousand years ago, unhedged and unpaliaded on any side, requiring no keepers to prevent bounding and buoyant youth from carrying home trophies of the golden furze, turning up little sods of moss; rolling, tumbling, and playing at its own sweet will, and altogether enjoying the happiness of unlimited liberty. It will be a satisfaction to the public to know that in the coming spring they will not glance down those pretty dells with the feeling that they may gather wild violets in them for the last time, or in the coming summer frisk along the finest road near London with a dread lest it should before they go again have its beauty blocked up by mansions. The Hampstead Vestry has, however, already appealed to the Board of Works against encroachments which are taking place round the Heath since it was bought by the Board. The following appeal was addressed to the Vestry by fifty-nine of the artists of London:—"Jan. 11, 1872.—We the undersigned artists, having learnt that the Metropolitan Board of Works have omitted from their recent purchase of Hampstead Heath many very important pieces of ground, and that your Vestry are taking steps in the matter, would urgently represent the great loss to the picturesque beauty of the Heath if these pieces were enclosed or cut off from the public ground. We are intimately acquainted with the different beauties of the Heath, and feel strongly that these beauties would sustain great injury should any buildings be erected on the above-mentioned pieces of ground. We therefore most earnestly request you to use every means to secure them for the public. We would also add our great desire that the Heath should be left as nearly as possible in its present wild state, to after which would in our opinion be a grievous mistake."

THE ESSENTIALS OF PUBLIC GARDENS.

It is desirable that a town park should offer a charming drive; so far charming that every townsman will feel it incumbent on him to give each stranger guest a full view of its attractions. These latter must lie, either in commanding views of the town itself and its environs, or in landscape effects which have been wrought out by skill and attention in the park itself. Neither Hyde Park nor the Bois de Boulogne offer any commanding range of view; the delights all lie in the neatly-kept roadway, the flanking lakes and parterres, the bright, green slopes of shaven turf; at Richmond Hill or on the Pincian at Rome, on the other hand, you forget the roadway, you forget the bits of pretty turflet, you ignore the cypresses, you are careless of the odour of flowers, for your eye, carrying all your perceptive faculties in its reach, leaps to the fair vision of flood and field and trees, which sweep away, in sun and in shadow, to the horizon.

Undoubtedly if the surface of adjoining country will permit, it will

be far less expensive to establish a park whose charm shall lie in exterior views than one whose attractions shall consist in what the professional men call (by use of an abominable word) its *gardenesque* features. Yet, with such economic purpose, it will never do to go too far in the country. It must never be forgotten with us that the men of equipages are by no means the only class who are to participate in our asthetical progress; the town park, to have its best uses, must not only be within easy reach, but it must have, too, its spaces of level ground to allure the cricket or the base-ball players. Areas should be ample enough to prevent the possible interference of these sports (which every sensible township would do well to encourage) with the enjoyment of a quiet drive.

While there is no need for making the wood of a public park a complete arboretum, I think that special care should be taken to give specimens of all the best known timber and shade trees, and that these should be definitely marked with their botanical as well as popular names, so that strollers might come to a pleasant lesson in their seasons of idleness. The particular habits of individual specimens and of forest growths might, I think, be safely and profitably noted as lending additional interest to them, and creating a sort of fellowship with the trees. Every forester knows that oaks and maples of the same species have yet idiosyncrasies of their own—one blooming a full fortnight before its neighbour, and another taking a tawny hue, while its companion is still in full array of green. In the garden of the Tuilleries there is a chestnut which enjoys the traditional repute of showing leaflets upon the twentieth of March (hence called *Vingt de Mars*), and the venerable old tree, well known to every frequenter of the garden, has come to have a character of sanctity by reason of this early welcome of the spring. In a field within sight of my own door, there is a sugar-maple which, by some fault in the planting, or some inherent defect in the tree, has made little or no growth these last six years, and which every August—a full month before the earliest of its companions—takes on a hectic flush of colour, which it carries, with the buoyancy of a consumptive, all through the autumn. This accident of colouring gives an individuality and interest to the tree which distinguishes it from all its stalwart and thrifty fellows. . . .

It is a common mistake, I think, to imagine that anything like a finical nicety in the arrangement of turf or walks or parterres is essential to the permanent and larger utilities of a town park. This indeed involves great cost, and diverts from larger and more important ends. A flock or two of South Downs, confined by movable hurdles, and under charge of some custodian, who might have his rural cottage at the gate of entrance, would keep turf in very presentable condition. After this good drainage; hard gravelled roads—subject to monthly rolling—and judiciously disposed clumps of shade are the main things; following upon which, as the town grows in taste or ability, the parterres of flowers and the arboretum and the observatory might be superadded.

But quite above and beyond our present question of treatment is the larger one of gaining, in due time, possession of available space. No town that counts upon its thirty or forty thousand inhabitants within the next score of years should neglect it. There can be no loss in its becoming a large landholder within its own territory. If the charming but costly disbursements of a park cannot be ventured upon at once, the land may at least be turned over into a town farm, where the town's poor may be set to the work of combing down its roughness or preparing it by slow degrees, earning their own support, meantime, for the richer ends in view. The scheme is by no means chimerical; scores of workers, through the less active months of the year, and who are dependent on the town for partial support, might thus be put to remunerative labour upon the town property. A judicious design of a park as a finality upon the land in question might underlie, in a measure, and qualify the regular farm labours. A well-appointed drive might gradually uncoil itself over the hills and through the cultivated flats, the wood crop out upon the cliffs, and the flowers unfold in their sequestered nooks. It seems to me that a park or garden, growing up in this way by degrees under the tutelage of the town, not fairly throwing off its economic and food-providing aspect until the plantations have ripened into fulness, would have a double charm. I commend the suggestions to such boroughs as keep their town's poor festering in some ill-ventilated almshouse, with limited grounds in the foulest suburb of the place.—*Rural Studies.*

New Park for Warrington.—It is stated that the Corporation of Warrington have purchased of Colonel Wilson-Patten, M.P., his Warrington residence and eighteen acres of park and garden land, for a town-hall and public park, for £22,000. The residence, called Bank Hall, is a noble Italian-English building, having for its front a lawn of several acres, and gardens of considerable size. The whole is walled round, is in what will soon be the centre of the town, and has a prospect for miles, both back and front, which scarcely can be intercepted.

Epping Forest Fund.—A public meeting was recently held at the Agricultural Hall in support of this fund, which has been established for the purpose of preserving Epping Forest for the people. Mr. McCullagh Torrens, M.P., presided. Captain Warner Dennis moved the first resolution as follows, viz.:—"That this meeting recognises the paramount necessity of open spaces being preserved for the recreation and enjoyment of the dense population of the east of London, and is of opinion that her Majesty's present Government utterly fails to appreciate the feelings of the people on the subject of Epping Forest." He said, at present there were about three thousand acres left, and as it had been clearly shown that those who had the sale of the present land did not value it at more than £5 per acre, it would at that computation only take £15,000 to purchase it, and secure it to the public at large in perpetuity. Whilst such large sums were laid out on West-end parks, the rule should be applied with the same liberality to Epping Forest, which was the favourite resort of the East-enders. The chairman suggested that a subscription of 6d. per head among the electors of the three eastern metropolitan boroughs would create a fund more than sufficient to answer all purposes.

Improved Wooden Pavement.—By the sanction of the Commissioners of Sewers a new principle, already successfully adopted in the United States, in Paris, St. Petersburg, and Vienna, has been lately introduced, and is now on trial of the south end of Bartholomew Lane. This pavement lays claim to the following advantages—absence of slip, noiselessness, elasticity, durability, and an even surface at all times. The construction of the pavement varies according to traffic and other circumstances. In Bartholomew Lane it is laid on a bed of sand, of sufficient depth to form a good guide, say from one to two inches; on that a flooring is placed, which consists of two thicknesses, one laid horizontally, the other transversely, each chicken consisting of a three-quarter inch board prepared with tar. Upon these boards blocks of wood measuring nine by three by five inches, are placed, and between each row of blocks a strip of wood one of three-quarters of an inch, is nailed to the flooring, the object being to steady the blocks in their places during construction; after being thus laid, the spaces or joints are filled with hot gravel, upon which hot tar or pitch is poured. This is rammed tight home, and again repeated until the spaces are filled up. Subsequently another application of tar is made over the surface, on which a dressing of fine gravel is thrown; when dried the pavement is complete. Its success remains to be proved.

Swimming Baths for London.—It is to be hoped that the death of Mrs. Browne, says the *Lancet*, will not deprive London of the munificent gift which she contemplated making in the erection, at her own cost of swimming baths somewhere in Hyde Park and Regent's Park. It is to be hoped that her Majesty will direct that the well-known wishes of the deceased shall be carried out, notwithstanding the absence of a will.

City Mortality.—Dr. Liddle, the Medical Officer of Health for Whitechapel, in a report which he recently presented to the local sanitary authorities, remarks that the intimate relation between defective ventilation and the mortality from tubercular diseases, convulsions in children, teething, atrophy, debility, infantile diarrhoea, and insanity, is not sufficiently understood; and until the public thoroughly comprehend the fact that these diseases are largely induced by the want of pure air, sufficient to sustain life, the mortality arising from the crowded localities in large towns, so that these maladies may be effectively dealt with. Hitherto the attention of local boards has been principally directed to the number of deaths from epidemic diseases, many of which are supposed to be caused by filth and defective drainage, and hence the formation of sewers and drains has been extensively carried out in the metropolis; but the numerous deaths which are caused annually by consumption, and its allied diseases have not been considered. As the rate of mortality is continually increasing for the relief of sickness and the support of widows and orphans, the building of asylums for the insane, and the providing of workhouse infirmaries for the debilitated and prematurely old, it is probable that local boards will direct more attention to the condition of the houses of the poor than they have hitherto done.

INSECTS, BIRDS, ETC.

INSECT POWDERS.

We owe to Professor Karl Koch, of Berlin, the first introduction of insect powders into Europe, he having, in the course of his travels in the East, become acquainted with their valuable properties. His first experience with them was at Tiflis, in 1836. Afterwards he found them used generally by the natives of the neighbouring countries, and on inquiry into the source from which the powders were obtained, he found that they were made from the pollen of certain species of Pyrethrum, more especially that of *P. roseum* and *P. carnatum*. The specific property lies in the pollen, and it is according to the greater or lesser amount of it that may be in the powder that it is more or less effective. The manner of using it is to scatter the powder about the apartment, and it has the effect of causing the insects to fall down as if dead or asleep, even bees and wasps succumbing under its action. The larger insects, however, by-and-bye recover as if coming out of a swoon; the smaller never come out of it. It is as if they had taken an over-dose of chloroform.

The way in which the powder ought to be made is to cut the

flowers and shake them over sheets. The pollen is in great quantities, and, like that of many conifers at the proper season, colours all the ground around; but it is difficult to get half-civilised nations to take the necessary precautions to secure it properly. It is easier to pull the plants up by the root, and by threshing and breaking them a greatly larger quantity of dust or powder is got than by the proper way of taking nothing but the pollen. Another consequence follows from their mode of procedure, which is that notwithstanding the great natural abundance of the Pyrethrums in their native countries, constant pulling up by the root before they seed, will, of course, sooner or later, exterminate the species altogether; and already there are symptoms indicating that such a result is approaching. Koch's discovery and proclamation of the virtues of this pollen as an insecticide has given rise to a great demand for it—a demand much greater than can be supplied from the plants or the districts which first were had recourse to for the purpose. Consequently, in the first place, the fabrication of the powder instead of being restricted to Pyrethrum roseum and *P. carnatum*, in Persia, Kurdistan, &c., has been extended to various allied plants in other districts; for all the Anthemideæ possess something of the same virtue in a greater or a lesser degree; and in the next place, even of these inferior species, instead of nothing but the pollen being used, every part of the plant that can be beaten down into dust is sold as the true insect powder. A very considerable trade is thus carried on in Dalmatia and other districts in the south and east of Europe in a powder manufactured from the common Ox-eye Daisy (*Chrysanthemum lencanthemum*), *C. montanum*, Pyrethrum *cetrariaefolium*, &c. These possess the repellent virtues of the true Pyrethrum to a greater or less extent, and, doubtless, in a much stronger degree than the same plants possess when grown in a more northern latitude and colder climate. M. Cautraine (as quoted in a recent number of the *Belgique Horticole*) particularly notes the scarcity of fleas in Ragusa, and other parts of Dalmatia, and ascribes it to the use of these plants. The plant itself (not the powder), it seems, is mixed among the litter of their cattle, and, by making this a persistent practice, the immunity of which he speaks has been obtained. We know nothing as to this from personal experience, but if it be as M. Cautraine relates, all we can say is that it is a great pity that the cultivation and use of the Anthemideæ has not been extended to the western side of the Adriatic Gulf.

The insect powder that is sold in this country is, from the causes above mentioned, very rarely to be had unadulterated. Indeed, the true—or perhaps it would be fitter to say the best—kind made from Pyrethrum roseum or *P. carnatum* is rarely to be met with at all. It is not difficult to distinguish between powder made from these species and powder made of other Anthemideæ, provided they are both genuine and composed of the pollen in which the virtue chiefly resides. Under the microscope the pollen spores of Pyrethrum roseum, for example, have needle-like projections, while those of the other Anthemideæ have them rounded. But the fact is, that, as I have said, in the majority of samples no spores of pollen are to be seen at all. We have examined a number for the purpose of endeavouring to determine from what species the powder has been manufactured, but we ended as wise as we began. In no instance have we found any pollen at all—nothing but broken fragments of epidermis, hair, flower, or branch. Another test is the smell. Good powder has no smell, and the colour should be a dull, dirty drab.

Californian Dye-Weeds.—The gathering of Orchella, a lichen which yields a beautiful purple dye, is, says the *Christian Advocate*, becoming a considerable business in lower California. This lichen is worth 125 dollars per ton in London, and the supply is inexhaustible. That which is used in commerce is gathered from the trunks and branches of trees.

The Last Years of Adanson.—Adanson, the French botanist, was about seventy years old when the Revolution broke out, and amidst the shock he lost everything—his fortune, his places, and his gardens. But his patience, courage, and resignation never forsook him. He became reduced to the greatest straits, and even wanted food and clothing; yet his ardour of investigation remained the same. Once, when the Institute invited him, as being one of its oldest members, to assist at a *séance*, his answer was that he regretted he could not attend for want of shoes. "It was a touching sight," says Cuvier, "to see the poor old man, bent over the embers of a decaying fire, trying to trace characters with a feeble hand on the little bit of paper which he held, forgetting all the pains of life in some new idea in natural history, which came to him like some beneficent fairy to cheer him in his loneliness." The Director eventually gave him a small pension, which Napoleon doubled; and at length a useful death came to his relief in his seventy-ninth year. A clause in his will, as to the manner of his funeral, illustrates the character of the man. He directed that a garland of flowers, provided by fifty-eight families whom he had established in life, should be the only decoration of his coffin—a slight but touching image of the more durable monument which he had erected for himself in his works.

PALM AVENUE IN THE BOTANIC GARDEN AT
RIO DE JANEIRO.

This magnificent avenue, which for elegance and majesty of aspect is perhaps unsurpassed, makes one long to possess such a glorious feature in our own country; for, however we may dislike formality, nobody can object to the striking and truly imposing effect thus produced. The palm employed for this purpose is the *Orcodoxa regia*, a kind distinguished by its lofty trunk and terminal head of noble foliage. The photograph from which the representation here given was prepared only takes in half the avenue, which is cut in two by the fountain and basin in the foreground.

For the following graphic account of this avenue, I am indebted to Mr. Herbst, of Kew Nursery, Richmond Road.

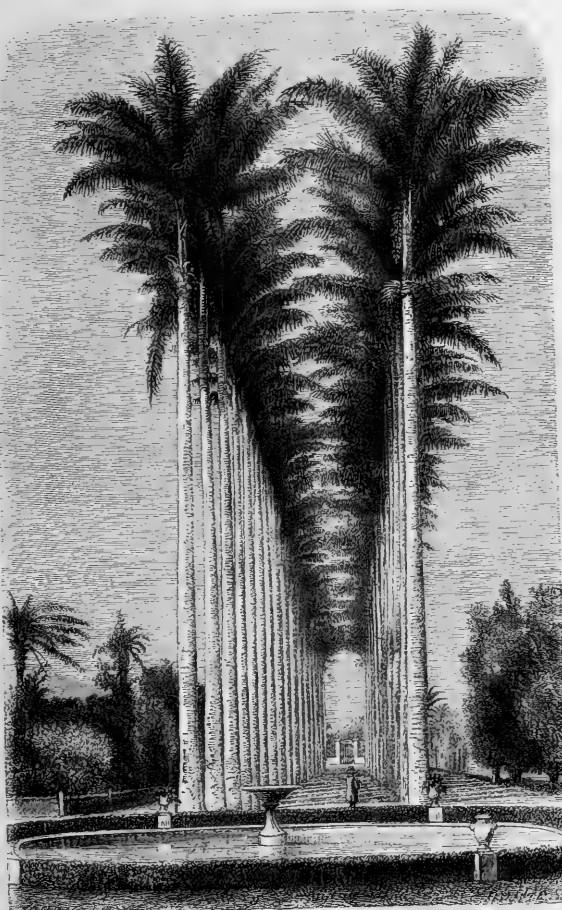

Strangers, he says, from northern countries are invariably struck with the appearance of this avenue, which is unrivalled for its regularity, extent, and beauty. It forms a colonnade of natural Corinthian columns, whose graceful bright green capitals seem to support an overarching dome of bright blue sky. When I saw it for the first time I felt sensations similar to those which I experienced on entering the great dome of Cologne, or that of Notre Dame; and this feeling of reverence and admiration never wears off with time. The trees of which it consists, ten years ago were about sixty feet in height to the top of the fronds, and were then said to be between forty and fifty years of age; I, however, took them to be younger. They may now be about seventy-five or eighty feet in height. The trunk of each of them is about four feet in diameter at four feet from the ground, and it goes on tapering gradually to a length of more than fifty feet, when it becomes united with another smooth thinner trunk from ten to twelve feet in height, formed of the bright green footstalks of the leaves, which again measure some twenty feet or more.

In young vigorous trees the leaves are considerably longer. The great beauty of this palm is its elegance and cleanliness of aspect; no ragged leaf beats about in the wind even at that great height; the over ripe yellow leaves unsheathe themselves of their own accord, and the trees look as clean as if they had

been trimmed by hand. The colour of the stem is a whitish grey, like that of light stone in dazzling sunshine, and although from top to bottom it is covered with lichens of all the colours of the rainbow, yet so small are they that you only perceive them by approaching the tree closely.

In the same garden exists the parent of these palms, which was planted during the last years of the last century, and is now above 120 feet in height. It is a noble tree, and, as it stands singly and at a considerable distance from other plants, its beauty and height can be seen to the best advantage.

J. CROUCHER.

Palm Avenue in the Botanic Garden at Rio de Janeiro.

very foliage being exceedingly pretty, and its habit of growth is so dense that it is certain to thoroughly cover the ground allotted to it. Anyone who may possess a few plants of this *Polemonium* should at once pot them up, and grow them on in the greenhouse. Should flower stems show themselves, pinch them out, and when the plants are of sufficient size give them a shift into larger pots; under such treatment they will soon become highly effective and handsome plants.—D.

A Florist's Puritanism is always coloured by the petals of his flowers—and Nature never shows him a black corolla.—Oliver Wendell Holmes.

Herbaceous Plants for Exhibition. — I have carefully scanned Mr. Brown's list of hardy perennials for this purpose at page 117, and am surprised to observe that hardy ornamental-foliated plants are entirely excluded. The schedule quoted simply requires that "hardy perennials" shall be furnished, but says nothing about their being in flower or otherwise. On several occasions I have exhibited twelve hardy perennials in pots at a country show, where the rule was to have at least eight in flower, the other four being plants having variegated foliage; and were the same arrangement adopted by exhibitors at South Kensington during the ensuing year, I am both sure that the collections would be improved, and that no reasonable judges would disqualify. Especially do I recommend for exhibition purposes the variegated variety of *Polemonium ceratum*, which is really one of the very handsomest of herbaceous plants, and one so far hardy that it may be wintered safely in sheltered places. In exposed situations, however, it is liable to suffer, and in such a case it is best to lift and plant in cold frames for the winter. As a bedding plant it is one of the most graceful and effective with which I am acquainted; its sil-

THE FRUIT GARDEN.

ORCHARD HOUSES.

WHEN Mr. Pearson (p. 105) stated that the future of British gardening would be "more and more under glass," he asserted what was quite correct; but when he added that a given area of ground could be as cheaply covered by a span-roofed house as a lean-to, he was as decidedly wrong. Given, for the sake of illustration, a space 12 feet wide to be covered with glass, 6 feet high at the sides and 11 feet at the ridge would give from ground line to ground line a girth of 27 feet 6 inches. Given a corresponding space in front of a twelve-foot wall, running at the same angle, but with a short hipped roof at the back, the result will be 6 feet of vertical glass, 12 feet of front, and 3 feet of back rafter, or in all 21 feet of girth, equal to just 6 feet 6 inches less than the span-roofed house. Bring the lean-to at a flatter angle to the top of the twelve-foot wall, and the girth will be 9 feet 6 inches, or 8 feet less than a span-roofed house. Take these measurements at the price of general orchard-house builders, and the result will be, according to the angle of inclination, a saving from one-fifth to one-third in favour of the lean-to house. Of course, I am presuming upon the wall being built; but if it is not, a twelve-foot wall will be built for less than a corresponding area in glass. Therefore, where walls are already existing it will be cheaper to build against them than to erect span-roofed houses. So much for facts; but the propriety of the arrangement is another matter, and a very difficult one to solve. If we again appeal to facts we shall possibly be confronted with the almost unquestionable truism, that the best fruits of past and present times, and a large proportion of the best plants, have been grown in lean-to houses. Still, this is no proof that equally good, and possibly superior, fruit, could not have been grown in houses with light on all sides. The grapes in Mr. Pearson's large vineyard last season (1871) were of undoubted excellence. If there is any mistake in Mr. Pearson's houses, it is their extreme size. For an unheated orchard house there is some reason in having it large, inasmuch as the frost-resisting power will be in proportion to the cubic contents of the warm atmosphere enclosed; but when we go to fire-heated houses, then, unless they are to contain large plants, there is no sense in building them disproportionately large. Fruit-houses twelve to twenty feet wide will be more economically managed than those twenty to thirty feet wide. For orchard houses, inconveniently large ones are certainly a mistake, as the fruit is so far from the glass as to render it quite impossible that it can attain the perfect colour and maturity necessary to fine quality. Hence we rarely see first-class peaches and nectarines from orchard houses; and if a market-gardener commences to grow stone fruit it is a rare exception to find him abandoning the trained trellis system of cultivation. With the excessive primpness that would lay each branch in its allotted space with almost mathematical precision we have no more sympathy than with the arbitrary rule which would confine every tree to its particular space, saying, So far shalt thou go, and no further. On the contrary, we believe nature cannot be curbed without injury, and that much of the gumming and canker, the dying off of branches and the plague of mildew, that often takes place, may be traced to those straights and stays which are used to strain a branch into exact position. That free and easy mode of training which allows a plant to fill a house, or two houses if it is disposed to do so, and which guides the branches without putting them in leading strings, is the proper system of management, and should not be confined to one variety of tree, but be extended to all trees alike. The future of orchard-house treatment is certainly in this direction, and when we begin to speak of the crop by pecks or bushels, rather than by dozens or scores, orchard houses will have attained their true position of usefulness.

What Mr. Pearson says of the uncertainty of the peach crop, and we might add the life of the tree, is very true; still, there

are ways and means by which, even north of the Trent, they are grown with great success. The finest peach trees I have ever met with in England were in Derbyshire; and no one can look upon the magnificent trees at Chatsworth without being struck with the fact that a cool, if not cold bottom, is best for them. At Chatsworth the roots during nearly the whole of the winter, forcing season included, must be under water, and yet such crops, size, and quality are rarely to be met with elsewhere. The success here and in some other places in Derbyshire certainly point out the advantage of having a cool bottom, calcareous soil, and an abundant supply of water. At the same time, in the interest of truth, the fact must not be ignored, that the peach has been, and we believe is still, very successfully grown with its roots in chambered and hot water heated borders, as, for example, at Ringwood, near Chesterfield, almost as cold a place as could be found in the Peak of Derbyshire. The success in this case may be regarded as one of those anomalies which sometimes crop out in garden experiences, and which puts our philosophy to a strange test. The true work of the accumulating glass erections of the country is not so much the production of peaches, as securing a good supply of those superior pears, plums, and apples that we should have from October through the winter months. Fine as a well matured peach may be in its season, a house-grown pear, apple, or Jefferson plum at the present time—Christmas-day—is infinitely finer. A few days back a friend sent us from Ireland, as a fill-up, among other seasonable fare, a peck or two of large but rather unfavourable-looking apples. As they were evidently of foreign origin they were relegated to the culinary department. Peeling some of them for a tart the odour of pine-apple became so manifest that the temptation to taste was irresistible. Well, out of a green, bruised, and battered skin, a little amber on the sunny side, came, when peeled, a fruit that for exquisite delicacy of flesh, juiciness and flavour would almost bear comparison with any pine-apple in Covent Garden. Upon closer examination—for up to this time we had bestowed nothing beyond a passing glance upon the fruit—we recognised our old friend the American Newtown Pippin, which had been purchased in the town of Derry at the price of half-a-crown for the stone of fourteen pounds; and nothing more truly delicious have we tasted for years. Much has been said of the Calville Blanc when grown as an orchard-house fruit, and though we know the Newtown Pippin possesses no speciality when grown in the open air in this country, we have written to America for established fruiting plants, and if upon trial under glass they prove as good as we anticipate, they shall have devoted to their cultivation as good a house as can be built. To bring these and similar really delicious fruits to perfection should be the mission of orchardists for the future. Erect good houses, prepare sound and healthy borders, and plant your trees so that they can attain something like proper size with full breathing space, and sufficient heating power to repel spring frosts, and then you may congratulate yourself that you have conquered the British climate, and rendered fruit cultivation a certainty.

A NEGLECTED FRUIT.

(THE ALPINE STRAWBERRY.)

The value of this strawberry is better appreciated in France than in this country; this is not because it cannot be grown as successfully on this as on the other side of the Channel, but because it has been so neglected with us that nine out of every ten who grow it do not know what it is capable of producing under good cultivation. The general custom has been to make an edging plant of it, or to plant it in some out-of-the-way corner, where it remains year after year on the same spot, until it degenerates so much as to assume the character of the wild strawberry found in our woods.

Very different is the result when it is treated with that generosity as regards culture which we bestow on the British Queen or Keens' Seedling. I do not hesitate to say that a greater weight of fruit can be grown on a given space planted with Alpines than with any other variety. The Alpine begins bearing early in July, and yields a constant succession of fruit till the frosty nights come on in October, thus extending the strawberry season nearly three months. All through the hot weather they are exceedingly useful for ices, jellies, &c., and a nice basket of fresh-picked Alpines is not to be despised at any time. Some people may say they are small, but I have

frequently gathered them as large as Black Prince. Don't grow them under walls, or hedges, or on narrow borders, where they are half killed by heat and drought; make your Alpine beds across one of the open quarters, where the ground has been trenched up and well manured two or three feet deep, but don't use rank manure. If the trenching and manuring have been done some time previously, so as to give the ground time to settle, so much the better. The best time to plant new beds is about the first or second week in August. I make my beds six feet wide; on a six-feet bed I plant five rows one foot apart, and about eight inches plant from plant in the rows. Before planting, let the ground be made tolerably firm, and afterwards give a good soaking of water. Alpines are harder than other strawberries, therefore no winter weather ever hurts them. In February I give them a good top dressing of rotten manure, and in May, I mulch them heavily and carefully with long litter or similar material, to save watering.

Anybody who has not yet grown the Alpine strawberry, and who may desire to give it a trial, may commence now in the following manner: Prepare the beds at once, so far as the trenching and manuring are concerned, and let the ground lie rough through the winter. About the first week in February procure a packet of seed of the French Alpine, red or white, or both if you prefer to grow both kinds. Sow in seed-pans, the same as you would do tomatoes or ordinary half-hardy annuals; place them in any house, pit, or frame, that will furnish a nice gentle heat; and as soon as the seedlings are large enough to handle, prick them off into other pans, boxes, &c. In April they ought to be strong enough to plant into the beds. They will begin bearing in August, and a good late crop may be anticipated, but not equal to that from August-planted beds. Don't forget the mulching, for this is most important in dry summers—it saves much labour in watering. Never let the beds stand more than two years in the same place if you can avoid it. A good plan is to destroy half the beds every year, and to replant in a fresh place.

E. Hobday, Ramsey Abbey, Hunts, in "Field."

MINIATURE APPLE-GARDENS.

I AM an old country resident, says "T. R.," in the *Times*, living in Hertfordshire, in a district celebrated for its cottage gardens, in which roses and apple trees are equally abundant. In other districts of England I am often grieved at seeing gardens neglected, or at best devoted only to potatoes and cabbages. Knowing, as I do, the comfort afforded to families by our best known and easily grown fruit, the apple, I am tempted to assist in spreading the knowledge of its culture, so that every cottager may grow his own apples. Before, however, I endeavour to describe the method of forming a cottager's apple garden, I must give a description—all gardeners know it!—of the stock to be employed to bring in the fruitfulness required in a small garden. There is a stock used to graft apples on with an almost fabulous name and origin. It is said to have been imported from Armenia, from the real site of Paradise. French gardeners in old times christened this tree the "pommier d'Paradis"—the apple tree of Paradise, and we, as humble imitators, named it the Paradise stock. Soon, however, the name was applied to other apple stocks of the same dwarfing nature, so that we have several varieties of this dwarf stock, which are called English Paradise stocks—kinds suited to our climate and likely to be very valuable to our cottage gardeners.

The first business of the cottager with the garden is to find a corner or square portion of it in which to form his plantation. This space he should mark out so as to hold trees in proportion to his ground. These he may plant in rows round the edges of his garden at a distance of four feet apart, or he may form a square, say twenty feet in extent, which at four feet apart will hold twenty trees. If a square piece of ground is selected it should be pl. ^{and} with apple trees grafted on the English Paradise stock, in the form of bushes, four feet apart row from row, and the same distance tree from tree in the rows. The centre of the space, four feet between each row, eighteen to twenty inches in width, may be cultivated for three or four years, till the trees have grown to the size of a fair-sized gooseberry bush, and in this space may be grown onions and dwarf potatoes, &c., so as to give a paying crop. This portion of the soil may be dug or forked, so as to loosen it, while the space on each side next the rows may be left solid, and be kept clean from weeds with the hoe. We have thus formed an apple garden—say of twenty trees. The sorts may be as follows:—Four trees of winter Hawthornden, four Duchess of Oldenburg, four Lord Suffield, four Damelous seedling or Wellington, and four Cox's Pomona. These are large apples, all great bearers, will be in season from August to March, and will pay the cottager well for the slight trouble of their cultivation. My bush apple trees, now four years old, of the above kinds, bore last season half a peck each. My plantation consists of 160 trees, and, in addition to the sorts

enumerated above, I have the Jolly Beggar, Betty Geeson; Méro de Ménage, Small's Admirable, and Warner's King. I mention the names of these prolific trees to assist the cottager's selection; the common Hawthornden and Keswick Codlin may also be included. Some kinds of dessert apples, too, are equally prolific, and may be cultivated by the cottager with advantage. I may mention one sort, Cox's Orange Pippin, which bears well and sells well, and would in itself be a fortune to a cottager.

And now as to their planting and management. The trees, as I have mentioned, should be planted four feet apart; the ground, after being dug, should have holes opened two feet in diameter and one foot deep; in a hole of this size the tree should be placed, and its roots covered with the earth taken from the hole; this should be gently trodden, and the planting is complete. The first season after planting no pruning will be required, as the growth of the trees will be very moderate; the second season, and every year afterwards, about the middle of June, every young shoot should be shortened to half its length with a sharp knife or pruning scissars, and in August the young shoots that have broken forth since the June pruning should be shortened to two or three inches. This is all the pruning required, and under this simple culture, the trees, if grafted on the Paradise stock, become sturdy fruitful bushes about the size of the gooseberry bush, and will give a supply of fine fruit all through the winter. Trees, may, I believe, be bought at 6d. and 9d. each, so as to be within reach of the labourer's pocket; or if a man is ingenious he may buy his Paradise stocks—say at 8s. per 100. The second year after planting he may graft them with the proper sorts.

NOTES AND QUESTIONS ON THE FRUIT-GARDEN.

Grapes in Bottles Filled with Water.—Has recent experience confirmed the good opinions that were advanced some few years ago in reference to this mode of preserving grapes after they had been cut?—*VITIS.*—[Mr. Tillyer, of Welbeck, says:—At the present time I have between 400 and 500 bunches of grapes in bottles of water, and I find they have kept as well as if they had been on the vines: the varieties are Black Tripoli, Muscats, Barchardt's Prince, West's St. Peter's, Trebbiano, and the Raisin de Calabre. They have been bottled about six weeks, and will keep up the supply till the end of February. After that, the grapes in the latest viney will be cut off and bottled, the sorts being principally Alicantes, West's St. Peter's, Lady Downes' Seedling, and Royal Vineyard. I have found no difficulty in keeping Lady Downes in good condition till the end of May in bottles of water, and there is the advantage of getting the vines in the late viney properly pruned and dressed for the next year's crop. The main thing to be observed in keeping grapes well in bottles is looking over the bunches frequently, and clipping off all decaying berries, attending to the temperature so as only to keep out frost and damp, and this can be best done by having a room fitted up for the purpose, as has been done here.]

Notes Concerning Pot Vines.—In the middle of October my pot vines had ripened and shed their leaves in a natural manner, they had never been allowed to remain dry during any time of their existence, their laterals had been removed, and the canes shortened to the required length as soon as they showed signs of ceasing to grow. On the 30th of October they were placed in a temperature averaging 55°, with a close moist atmosphere; they are still kept no warmer than this during cold weather, but are allowed a higher temperature during sunshine. As soon as the buds were seen to be swelling, air was given, and has never been taken off since. Treatment very similar to this will continue till the flowers are set. My object in writing this is to introduce some notes concerning root action. I have more than once stated very positively, in opposition to several eminent gardeners, that root action in the vine is never visible till a considerable amount of foliage has been made. Well, about a month after these vines had been placed in the above-named temperature, and the buds were swelling perceptibly, I examined the roots and found to my surprise that they appeared in full vigour, and the feeders, in myriads, were plump and of a greenish-white colour. Now, thought I, have committed a mistake in contradicting men of half a century's experience, and after all finding that they were right, and that I was wrong. Meanwhile the buds continued to swell, and in a few days I examined the roots again, and found to my relief that the fibres were fast decaying, and that, although the roots were plump and healthy, there was no sign of extension; the rootlets I had seen on the first examination were late and not early ones. My former observations were confirmed, and I was spared humiliation. The canes have now broken regularly and strongly all the way up, quite as strong at the lower as at the upper end, and I have no doubt new root action will soon commence, if it has not already done so. Is it the habit of other plants besides vines to make upper growth before the roots move?—*W. TAYLOR, London.*

On Trade in Dried Fruit.—The arrivals of currants in December consisted of 3,339 tons, and we have had a total, since the 23rd of August—the first day of the season—of 30,300 tons imported into London. This, with the old stock, has made 32,300 tons to work upon, and as the London stock is reported by dock companies and wharfingers to be 11,660 tons, it may be calculated that for all purposes 20,637 tons have been delivered from warehouses or ship's side. Of Valencia raisins, the December arrivals of 544 tons bring the total receipts of the season to 9,062 tons, against 7,660 tons in 1870.

ASPECTS OF VEGETATION.

SCENE IN A BRAZILIAN FOREST.

To those who are not privileged to travel in tropical climes, it is interesting to witness pictorial evidence of the beauties of tropical scenery. This is particularly true of the gardener whose pleasure and duty it is to develop the highest beauty of the vegetation in his charge; for he will do this effectually, or otherwise, just in proportion to his familiarity with the abounding beauty and variety exhibited by vegetation in its more favoured haunts in countries from which the different objects of his care come. We lately illustrated the giant herbaceous vegetation of Siberia, and now go south to the magnificent forests of Brazil, letting Mr. Darwin and our illustrations describe them for us.

After delineating the elements of the scenery, "it is hopeless," says Mr. Darwin, "to paint the general effect. Learned naturalists describe these scenes of the tropics by naming a multitude of objects, and mentioning some characteristic feature of each. To a learned traveller this possibly may communicate some definite ideas; but who else, from seeing a plant in an herbarium can imagine its appearance when growing in its native soil? Who, from seeing choice plants in a hothouse, can magnify some into the dimensions of forest trees, and crowd others into an entangled jungle? Who, when examining in the cabinet of the entomologist the gay exotic butterflies and singular cicadas, will associate with these lifeless objects the ceaseless harsh music of the latter and the lazy flight of the former—the sure accompaniments of the still, glowing noonday of the tropics? It is when the sun has attained its greatest height that such scenes should be viewed; then the dense splendid foliage of the mango hides the ground with its darkest shade, whilst the upper branches are rendered, from the profusion of light, of the most brilliant green. In the temperate zones the case is different—the vegetation there is not so dark or so rich, and hence the rays of the declining sun, tinged of a red, purple, or bright yellow colour, add most to the beauties of those climes. When quietly walking along the shady pathways, and admiring each successive view, I wished to find language to express my ideas. Epithet after epithet was found too weak to convey to those who have not visited the intertropical regions the sensation of delight which the mind experiences. I have said that the plants in a hothouse fail to communicate a just idea of the vegetation, yet I must recur to it. The land is one great wild, untidy, luxuriant hothouse, made by Nature for herself, but taken possession of by man, who has studded it with gay houses and formal gardens. How great would be the desire in every admirer of nature to behold, if such were possible, the scenery of another planet! yet to every person in Europe it may be truly said, that, at the distance of only a few degrees from his native soil, the glories of another world are opened to him. In my last walk I stopped again and again to gaze on these beauties, and endeavoured to fix in my mind for ever an impression which at the time I knew sooner or later must fail. The form of the orange-tree, the cocoa-nut, the palm, the mango, the tree-fern, the banana, will remain clear and separate; but the thousand beauties which unite these into one perfect scene must fade away; yet they will leave, like a tale heard in childhood, a picture full of indistinct, but most beautiful figures."

TREE, SHRUB AND PLANT LABELS.

(Continued from p. 156.)

For fruit trees, roses, &c., perhaps the simplest and best kind of label is a common wooden one, three inches long or so, and with a hole bored through at one end, through which a copper wire may be passed to attach it to the tree, the name being written on while the paint is moist, and the copper rather loosely though securely bound round the branch, so as to allow for its expansion. In some places where large collections are kept it is usual to put numbers to the plants, and enter the names with those numbers in a book. In such cases all that has to be done is to provide suitable numbering material, and the best known are little narrow strips of lead, on which the number is impressed with type for the purpose, and then the strip is wrapped round a small branch rather loosely but securely.

For all common bedding and similar plants, ordinary wooden labels are at once the most convenient and the simplest. If you require them of a somewhat lasting character, dip the ends in tar or pitch. In most gardens it is the practice in writing those wooden labels to write the name from the part that goes in the ground to the top—a bad way, inasmuch as the label always begins to decay at the base, and thus the beginning of the generic and specific name gets obliterated, while the end of it may be quite legible. Always begin to write it at the top, and then, if it does decay at the bottom, the commencement of the names will, in most cases, lead to their recognition. This may seem a small matter, but really is of much importance where there are many plants named with common wooden labels. It becomes as easy to write from the top after a little practice as the other way. In writing the names always begin as near the top as possible. The wooden labels are most readily made from laths if they be not bought by the bundle, in which way they are now frequently sold. They are also generally used for pot plants, and are the best for general purposes. When we have nice specimen plants it is often desirable to furnish them with more permanent and horizontally written labels. The readiest and best way, however, we have found of doing so is as follows:—There are little zinc labels of several shapes sold by seedsmen, and usually written upon with some acid, but they are generally unsatisfactory when so written, and not sufficiently legible. By painting these with a little white paint made without oil, you may write upon the surface with common ink, and by placing over the lettering and general surface of the label when dry a touch of the best copal varnish, a neat, effective, and most convenient label for pot plants is the result. The labels can be written by anybody, and are as quickly and conveniently done as any. It is best to write each letter distinctly—to "print" it after a fashion, in fact. Of course there are others equally suitable, but one may obtain a dozen of these for the price of one of the impressed labels, and they may be used again and again, like the cast-iron labels recommended for trees. We are the more desirous of recommending these economical and efficient articles from having frequently seen the labelling of trees, &c., given up in disgust in consequence of the failure of expensive glazed and other labels. Where large collections of camellias or any other hard-wooded plants are grown, the small strips of lead, with the number impressed on one end and the strip folded on so that the numbered end shall be presented to the eye, are excellent, as well as for roses, fruit trees, &c., in the open air.

With regard to the way of writing a label, it is generally a good plan to give a place to what is called the "common name," if that name has any basis, not otherwise. The Columbian maple, the dove plant, the maiden-hair—these and such as these that are really "common," or have some recognition, or some meaning, or association, should be given; but to merely translate the Latin name, to give us something like the "accumulate-leaved *Sarcocglottis*," or the "long-brained barn-bane," as they do in Kensington Gardens and St. James's Park, is absurd. Therefore we never put a "common name" upon a label unless it be really such, and if the plant has any peculiar use or association that is not expressed by this common name, it is sometimes desirable to record it. Never omit the generic name in full, as they frequently do at Kew. The native country, in addition to the scientific name, should always be given; to put the date of introduction or natural order is unnecessary. One may see labels in some botanic gardens so much covered with authorities and on this or the other as to scare away the visitor whom they ought to attract. Of course this refers to larger and important subjects; for small ordinary plants the single name only should be used.

After trying every way we are quite satisfied that the best way of all is to have a stock of strong but neat iron labels, and have some person to rewrite them occasionally in winter. The most suitable size for general purposes of labelling young trees, &c., is about nine or ten inches high, one inch wide in the shank, the head four or five inches across, and one and a half or two inches deep. Of course these cast-iron labels will only be obtained by those who really wish to name their choicer trees, shrubs, &c. In the first instance we made a model in wood of the desired kind of label, and, sending it to Glasgow, had a number cast at a cheap rate per hundredweight—getting somewhat more than a hundred labels per hundredweight. In writing the labels it is best to first write the outlines, and then fill in rather thickly; the paint to be finely strained, of course.

The following description of a new garden label, contributed to the *Journal of Botany*, by Professor A. Church, of the Royal Agricultural College, Cirencester, will be of interest. The Professor says:—"The indestructibility of solid paraffin suggested to me its use for the preservation of printed plant labels. The plan having proved successful, and the 'paraffined' labels having resisted the adverse atmospheric influences of two seasons, I cannot but hope that more extended trials will confirm my conviction that a permanent garden

st
br
gr
d
x
ct
pure

label, legible and inexpensive, has been attained. The following is a brief description of the mode of preparing the labels.—Print the names, &c., of the plants on stout, smooth, white paper of suitable dimensions and form. Prepare cast-iron label-holders with a flattened spike to keep them straight in the ground, and with the upper expanded portion so contrived as to have a sunk flat space about a quarter of an inch deep, and the right size for the reception of the printed label and its protective glass cover. Paint this sunk space with several coats of good white paint, and allow it to dry thoroughly. The next step is to unite the label to the glass plate with paraffin. The paper-label and glass being cut to the same size, the latter is cleaned and kept hot—about as hot as boiling water—while the label is being dipped into a bath of melted paraffin. The label is then quickly pressed on to the hot glass, a board and a weight being put upon both. When cold, the glass with its adherent label is placed in the sunk space of the label holder, and secured with good putty. Subsequently, a coat or two of paint on this putty will keep all secure. The above directions are much easier to carry out than they appear to be at first sight, while several contrivances and precautions will suggest themselves to anyone who carries them out on a large scale. For instance, the glass plates may be kept hot in an oven, and removed with a pair of crucible-tongs as wanted, while another pair of tongs or pincers will be useful to hold the labels during their immersion in the melted paraffin. Here it should be stated that the best paraffin is that which is freest from any kind of fat or grease, and melts at a temperature at least above 56° centigrade. It might be found advisable to imbed the label and glass in paraffin, or to modify the plan of fixing the label to the glass by putting it, soaked in paraffin, between two sheets, but the principle of all these modifications is identical. The air and rain are excluded, and cannot give rise to the discolouration of the label."

On the above attempt of the able Professor we have only to remark again that no label deserves general adoption in a large garden which will not permit of being used again and again, if from any cause the plant it was originally used for disappears from the garden, or perhaps receives another name; and as to permanence, that question is already settled. Iron labels, painted black, and with white lettering, covered with a coat of copal varnish, done eight, seven, and six years ago in the herbaceous department of the Botanic Gardens in the Regent's Park, are now as legible as ever. This is permanent enough for all ordinary purposes. Grand old oaks or other objects no more liable to suffer from vicissitudes than granite rocks, may require as permanent labels as can be devised.

THE ARBOREUM.

TREES FOR CITIES AND TOWNS.

MANY think that it is difficult or impossible to grow many kinds of trees in London. This is an erroneous notion. The after-mentioned trees are such as I know will grow in London, and, consequently, in our other large cities:

THE HORSE-CHESTNUT.—This thrives in London where it is well planted, and the trees retain their leaves longer than they do in Paris; therefore, they are much fresher, and more agreeable to look upon in autumn. The most conspicuous plantation, perhaps, is the avenue in Regent's Park, where, however, the trees are crowded, and the soil is very inferior compared with much that may be found in other London parks. It should be borne in mind that when street trees are planted on the Continent they receive proper soil, and are otherwise treated so as to ensure good specimens. With us the rule has been the reverse of this. It is by mere accident that most of the fine trees seen in London have got their heads above the crowd of young trees and shrubs among which they have been carelessly stuck into the ground. In the squares and in the open roads of London, such as that of the new Thames Embankment, the horse-chestnut, if properly planted, would in due course become—what it is already in our parks—the noblest in flower of all our stately forest trees, and we may add that the double variety lasts much longer in flower than the common form. The red kind would also thrive well, as indeed would all other sorts of chestnut.

ROBINIA (FALSE ACACIA).—This thrives in all parts of London; but it is rarely so planted as to ensure more than half its full development. It retains its verdure till late in autumn, then sheds its leaves quickly, and goes to rest for the winter. It has, in this respect, an immense advantage over the lime, which occupies half the summer in shedding its rusty leaves. The round-headed variety, which forms such compact and glorious masses of verdure in various cities in Italy, is well worthy of attention; and so is the pyramidal one, which has a habit like that of the Lombardy poplar. It is a peculiarly graceful tree, and especially adapted for positions in towns and cities where a tree with wide-spreading branches might be objectionable. Its columns of graceful verdure may rise in the narrowest streets, or from the smallest enclosures round public buildings, &c., without shutting out light, or giving rise to any objectionable drip. This variety may be seen in pretty good condition along the flower-walk in Kensington Gardens. There are other varieties of this elegant tree equally important, such as *sophoræfolia*, *macrophylla*, *microphylla*, and *Decaisneana*.

GLEDITSCHIA.—This is much less known as a town tree than the Robinia, but is even more valuable, retaining, as it does, its leaves in a perfectly green condition till late in autumn, and attaining, under favourable circumstances, a height of nearly eighty feet. A tall and well-developed Gleditschia is more beautiful than the finest Robinia; indeed, taking stateliness and grace into consideration, I know of no tree to surpass such specimens as that of the Gleditschia in Professor Owen's garden in Richmond Park. I have observed these Gleditschias thriving in small gardens in London, where they have been most carelessly planted; therefore, there would be no difficulty in growing good specimens of them in our streets and squares.

MAPLES.—Nearly all the species of this noble family may be grown well in London, and any of half-a-dozen distinct species of maple are better worthy of a place in town than the common lime. Among sorts to be recommended may be mentioned the Great Columbian, the Neapolitan, the Hungarian, the Siberian, and the Norway maples.

ALDERS.—Of the cut-leaved kind there is a fine old tree in the Duke of Buccleuch's garden at Montague House. This variety, which forms such a distinct-looking tree, attains as great a height as the common kind, and there are other sorts that thrive equally well in towns.

BIRCH.—The weeping birch is quite at home in London, and the nobler species, such as *Betula nigra*, will also succeed, and may be seen in Kensington Gardens and Hyde Park.

CELTIS OCCIDENTALIS.—Of this there is a fine tree at Fulham, overhanging the King's Road.

THE COMMON ASH.—This and its allies, some of which differ greatly from one another in appearance, make excellent town trees. A good collection of them may be seen in perfect health in Kensington Gardens, near the pretty little cottage on the south bank of the Serpentine. They are, however, too much crowded, and begin to want relief in the way of thinning.

THE TULIP-TREE.—This is quite at home in London, and is one of the most valuable of city trees.

THE FLOWERING ASH (ORNUS EUROPAEA).—This thrives perfectly, and is very ornamental in early summer.

PYRAMIDAL PLANE.—This is a close-growing variety of the common London plane, and would, doubtless, make an equally good town tree.

POPLAR.—Of the many species and varieties that exist of this, the Abele poplar is, perhaps, one of the finest which we have for towns.

PTEROCARPA CAUCASICA.—This has noble compound leaves, and will do well as a town tree.

AILANTUS GLANDULOSA.—This thrives famously in towns, both in America and in Europe. Good examples of it may be seen both in Oxford and in Cambridge terraces, Edgware Road.

Among the preceding are some of our largest town trees. There is, however, a host of trees smaller in stature, but more beautiful in bloom, and well calculated to relieve the monotony resulting from planting any of the larger kinds in quantity. These are the thorns in splendid variety, the snowy *Mespilus*, the almond, the apricot tree, the cherries, double and single,

the Judas tree, the deciduous cotoneasters, the quince, the laburnums, *Gymnocladus canadensis*, *Kelreuteria paniculata*, *Salisburia adiantifolia*, such vigorous and hardy magnolias as *acuminata*; the Dutch medlar, the double-blossomed peaches, the cherry plum, *Pyrus* in great variety, Weeping Sophora; the lilac, and the Weeping Wych elm. Many others might be named; but these will suffice to show that if we lack variety in city plantings, it is not for want of materials. G.

WEEPING TREES.

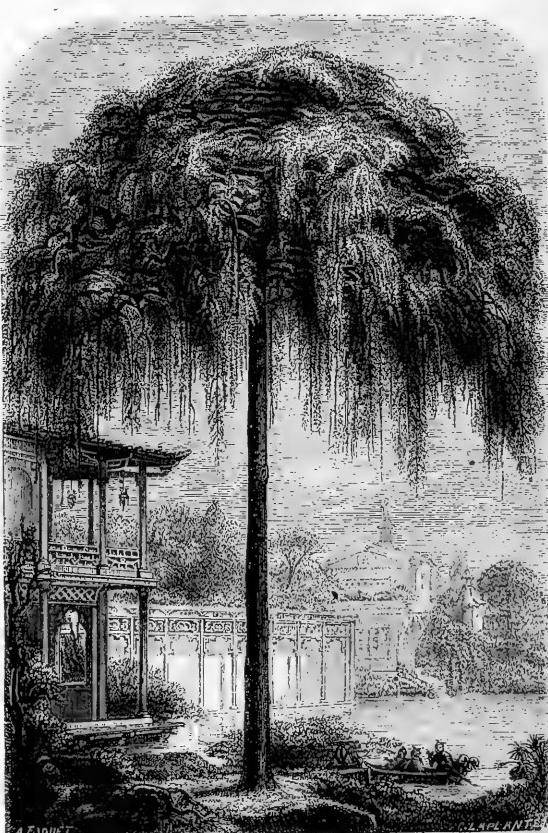

As yet we do not know the full value of weeping trees. It is a peculiarity of most weeping trees not to show their full beauty of character till they have attained a considerable age. Who knows anything of a weeping beech who has seen only a young specimen recently planted? Why, it is passed by as a mere curiosity. But give it a generation, and it becomes as picturesque as a gale-tossed ship. So it is with the weeping mountain elm, of which there is such a noble specimen on the lawn of the Botanic Gardens in the Regent's Park. Some species, it is true, show their beauty from an early age; but the above-named marked examples point to the probability that we cannot judge of the effect that will finally be produced by kinds obtained in recent years.

One of the most beautiful of all weeping trees is the weeping form of that fine tree the Japanese Sophora (*Sophora japonica pendula*). When well developed, it is attractive in winter or summer. It is more picturesque in outline than the weeping willow, while the shoots hang most gracefully. It is rather a slow grower, its only fault; like the normal form, it would thrive well on dry soils. This tree is more esteemed on the Continent than in this country, and there are better specimens of it there. It probably requires the climate of the south of England to give it a fair chance of attaining perfection.

As to the position suited for this tree, there is no fairer object for isolation in some quiet green bay of the pleasure-ground or lawn. It should never be crowded up in a plantation or shrubbery with a number of ordinary trees, which, if they do not rob it at the root, or shade it at the top, will prevent its beauty from being seen. We should be glad to learn the size of the best specimens of this tree now in this country.

BEECH TREES AND LIGHTNING.

WHILE travelling through some of the extensive forests of North America, in the summer and autumn of 1834, I was astonished to find that during a thunder-storm many of the inhabitants took shelter under the nearest beech tree, believing that such trees are never struck by lightning. Wishing to investigate the truth of this opinion, I made inquiry in various districts through which I passed, but in none could I hear of a single instance of a beech tree having been struck by the electric fluid, although I had seen elms, oaks, chestnuts, and ash trees more or less disfigured by it, both in the United States and the Canadas. The stems of elms and oaks were generally torn into long narrow strips, while the ash was in elongated detached masses of various sizes. On returning to Edinburgh, I made inquiry in various parts of Britain to ascertain if such was the case in regard to the beeches in this country. Although I have seen and heard of many species of trees being more or less injured; not one proved to be the beech. From this seeming exemption, I was inclined to think that there must be something in the constitution of the beech different from other trees, rendering it less susceptible to the electric fluid. I may here mention one circumstance which is pretty well known to all proprietors of beech forests; that is, the scarcity of vegetation in such places; and in close beech woods nothing is seen but the brown decaying leaves of many successive years. In the American beech woods, as well as some of those in Britain, we do find a few herbaceous plants peculiar to such places, totally different in appearance from the plants found growing under any other species of timber trees. Under the beech trees in American forests we find the different species of "Indian Pipe" (*Mono-tropa uniflora* and *M. lannigiosa*), also the "Cancer Root" (*Epiphegus virginianus*), while the *Mono-tropa Hypopitys* is indigenous in some beech woods in England. These plants have, more or less, a waxy appearance, of a peculiar whitish-brown colour, devoid of leaves, but covered with scale-like bodies. During a recent tour through England, I was interested to see at Mr. Smith's, at Worcester, a large weeping beech, which was struck by lightning during the month of June 1857. This tree is twenty-five feet high, with a stem six feet in

The Weeping Sophora.

circumference at base, and branches spreading horizontally at top. The spread of the branches varies from thirty-five feet to forty feet in diameter. This beech, instead of being riven in pieces like the generality of lightning-struck trees, has the bark on the upper horizontal portions of the branches injured, just looking as if they had been scalded with a hot iron. The health of this tree does not appear to have suffered, as the points of the branches then struck, as well as the secondary ones immediately below the seared portions of the large branches, have grown quite as freely, and continue as healthy

as those which were untouched by the electric fluid. The three main branches injured vary from twenty-one inches to twenty-seven inches in circumference, and the portion of bark riven along their upper surface varies from four to five inches in breadth, in small, irregular flakes, standing quite upright. The electric fluid must have passed off by means of the pendent branches, as no trace is observable on the surface of the horizontal ones beyond ten, thirteen, and sixteen inches in circumference, nor is there the slightest appearance on the stem of any electric fluid having passed down it, which is not unfrequently the case with some lightning-struck trees. Owing to the peculiar effect produced by lightning on this weeping beech, I am still inclined to think that there must be something in the constitution of the beech tree which ought to be investigated, and which renders it incapable of being injured to the extent of other forest trees. Still, large beech trees may occasionally be struck, and show no more injury than the weeping beech at Worcester.—J. McNab in "Proceedings of the Botanical Society of Edinburgh."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Extinct Sequoia (Wellingtonia) Forests in England.—In the December number of the *Geological Magazine*, Mr. Carruthers, F.R.S., of the British Museum, has figured and described two new species of fossil coniferous fruits from the Gaultbeds of Folkestone. He states one species to be allied to the existing *Sequoia* (*Wellingtonia*), and shows that they point to the existence of a coniferous vegetation on the high lands of the Upper Cretaceous period, which had a fauna similar to that now existing on the mountains on the west of North America, between the thirtieth and fortieth parallels of latitude. No fossil referable to *Sequoia* has hitherto been found in strata older than the Gault, and here, on the first appearance of the genus, we find it is associated with pines of the same group that now flourish by its side in the New World.

The Hemlock Spruce (*Abies canadensis*).—The grandest and most solemn of all the forest-trees in the mountain regions. Up to a certain period of growth they are eminently beautiful, their boughs disposed in the most graceful pagoda-like series of close terraces, thick and dark with green crystalline leaflets. In spring the tender shoots come out of a paler green, finger-like, as if they were pointing to the violets at their feet. But when the trees have grown old, and their rough holes measure a yard and more through their diameter, they are no longer beautiful, but they have a sad solemnity all their own, too full of meaning to require the heart's comment to be framed in words. Below, all their earthward-looking branches are sapless and shattered, splintered by the weight of many winters' snows; above, they are still green and full of life, but their summits overtop all the deciduous trees around them, and in their companionship with heaven they are alone.—*Elias Vener.*

A Tale about Cedar Trees.—Once upon a time, in a certain private park on the south side of London, there stood some cedar trees, both tall and handsome, lending a sweet and beautiful air to the swelling ground on which they grew. But on an evil day the park was given over to the tender mercies of builders and surveyors. "These trees," said one master builder, "are very precious; they would make innumerable cedar pencils, and would in that way realise a great deal of money." He therefore gave orders to his men to cut them down and make them into square logs. Then he said to a timber dealer: "Come, see my timber, and buy it." So the timber dealer came, but he did not buy; on the contrary, he said, "Foolish man! you have destroyed these beautiful trees, and now they are of no use except to burn; these are not the cedar trees of which pencils are made, and their wood is good for nothing else." These trees were worth a hundred guineas each as objects for park embellishment as they stood, and now they are scarcely worth carting away." Moral:—Don't cut cedar trees down, especially with the view of making cedar pencils or much money out of them.—*ALFRED DAWSON.*

Poplars as Town Trees.—I have a very beautiful poplar on my lawn which I received from Simon-Louis Frères, of Metz, now some seven or eight years since, under the name of *Populus Eugenii*, said to be a hybrid between *P. canadensis* and some other species. My tree is about thirty feet high, and differs from all others; it is graceful, and most rapid in its growth, having some resemblance to the Black Italian poplar; but it is far less spreading in its growth, and seems well worthy of propagation as a town tree—for anyone who will look at the groups of poplars behind Whitehall will see that the poplar is a town tree. The poplars I allude to (*Populus canescens*, I believe) in summer are slightly pendulous, and on the whole form the most graceful groups of trees I ever saw. That variety of *P. alba* called *P. acerifolia* is also well worthy of a place in our parks. Its leaves when turned up by a slight wind are of silvery whiteness and very plentiful; both this and *P. Eugenii* strike freely from cuttings.—*SILVA.*

Trees.—There is a mother-idea in each particular kind of tree, which, if well-marked, is probably embodied in the poetry of every language. Take the oak, for instance, and we find it always standing as a type of strength and endurance. I wonder if you ever thought of the single mark of supremacy which distinguishes this tree from all our other forest-trees? All the rest of them shirk the work of

resisting gravity; the oak alone defies it. It chooses the horizontal direction for its limbs, so that their whole weight may tell—and then stretches them out fifty or sixty feet, so that the strain may be mighty enough to be worth resisting. You will find that, in passing from the extreme downward droop of the branches of the weeping-willow to the extreme upward inclination of those of the poplar, they sweep nearly half a circle. At 90° the oak stops short; to slant upward another degree would mark infirmity of purpose; to bend downwards, weakness of organization. The American elm betrays something of both; yet sometimes, as we shall see, puts on a certain resemblance to its sturdier neighbour. It won't do to be exclusive in our taste about trees. There is hardly one of them which has not peculiar beauty in some fitting place for it. I remember a tall poplar of monumental proportions and aspect, a vast pillar of glossy green, placed on the summit of a lofty hill, and a beacon to all the country round. A native of that region saw fit to build his house near it, and, having a fancy that it might blow down some time or other, and exterminate himself and any incidental relatives who might be "stopping" or "tarzing" with him—also labouring under the delusion that human life is under all circumstances to be preferred to vegetable existence—had the great poplar cut down. It is so easy to say, "It is only a poplar!" and so much harder to replace its living conc to build a granite obelisk!—*Olivier Wendell Holmes.*

Killing Tree-Stumps.—Within these last few years I have remodelled my plantations and shrubberies, and rooted-out cart-loads of ill-grown trees, replacing them with curiously grafted trees more suitable for garden decoration than the common material so persistently planted even yet by those whose knowledge of arboriculture extends no further than that of time-honoured timber trees. Not to make too great an opening at once, a large tree was left at intervals, until the new ones get up a little, and these I wish to destroy by degrees as may seem desirable. The question is, therefore, how can this best be done, as the roots cannot be dug out, and to cut them off at or above ground would only result in the production of ugly stumps, bristling with strong shoots. The only effective way I can think of is to remove entirely a ring of bark in the early autumn before the descent of the sun, and this I purpose trying next autumn, if no one can, from experience or inductive reasoning, suggest a better plan. The trees are from twenty-five to thirty years planted. I thought at first to head them down and cover them with ivy, but a vigorous young oak upon which the experiment was tried threatens (for a time at least) to out-grow the ivy. In order to better understand the case on which I seek advice, it may be well to explain that the south plantation, specially intended to block out a row of houses, is about four hundred feet long, and was originally planted on the level, but having now adopted the raised and undulating style, I have raised the ground from three to four feet with rich soil throughout the entire length. This affords excellent material for the new trees to root and become established in. And to prevent injury to those old trees which for a time it is desired to retain, a ring of loose stones has been built round the trunks. This mising of the soil, as well as the planting of new trees at a higher level, of course, precludes the digging out and eradication of the older ones when it is wished to get rid of them.—W.T. [As you have rather deeply covered the roots of the older trees, it is likely some of them will perish from this cause. Your best course is to plant ivy and other vigorous climbers against any tall stumps you may have, cutting in the top where that is interfering with the younger and rarer trees. Trees, like weeds, may be destroyed by persisting in cutting off their leaves.]

SEASIDE TREES AND SHRUBS.—Mr. Barnes recommends *Cupressus macrocarpa* as the best conifer for planting in exposed situations near the sea, but I venture to advise the use of it in that way with caution. Twenty years ago this very beautiful tree had so fairly taken possession of my better affections that I was in raptures with it, recommending it and planting it in all directions. In one instance I induced a gentleman to allow me to plant him a full thousand in one plantation near the sea; but, alas! of that large group few now remain, to tell their tale of hardships; all except a few solitary unhappy objects have disappeared, so that *Cupressus macrocarpa*, however handsome in some situations, is not the tree to plant to "any required extent." Far from it—it will not stand direct exposure to the sea in most cases; in some quiet sun-spot nothing can be more handsome than this fine cypress; but as a conifer there is no pine to equal *Pinus austriaca*: it will stand exposure anywhere and everywhere. I reside, as it were, on the sea-beach, and I could point to some fine examples of *Cupressus macrocarpa* planted by myself in 1850-51; but I could also point to many failures.—*W.M. BARON, Sketty, Siccanea.*—[From the situation in which the Monterey Cypress grows on the Pacific slope, we should be inclined to say that, unless the climate be a peculiarly harsh one, it is likely to prove a noble seaside tree. At Monterey it stands on the sea-shore, continually tossed by the cool Pacific breezes and storms, and the trees attain such size and character, that they almost remind one of tall Cedars of Lebanon. We hope shortly to engrave a drawing, by Mr. E. Vischer, of San Francisco, in which the trees and their storm-tossed home are beautifully shown.—*CONDUCTOR.*]

THE FLOWER GARDEN.

IVY-LEAVED PELARGONIUMS.

In many localities great difficulty has been experienced during these last few years in satisfactorily cultivating the various varieties of bedding verbenas and calceolarias, and the result is that in some establishments their cultivation has been nearly if not altogether discontinued. The useful Pyrethrum "Golden Feather" has, in some degree, supplied the loss of the yellow calceolaria, and in the various varieties of ivy-leaved pelargoniums may, I think, in some instances at least, be found substitutes for the verbena; and this will possibly be admitted to be the case when it is remembered that this section of the pelargonium family has of late years been much enriched by what may be termed an infusion of zonal blood, and that many of the hybrid varieties thus obtained are found to be exceedingly graceful and really useful bedding plants. In dry seasons, too, on light land, they will be found to succeed admirably, while under similar circumstances verbenas and calceolarias would probably perish. In fact, in their cultivation as bedding plants, neither a rich soil nor an abundant supply of water is necessary or desirable.

Most of the older varieties of ivy-leaved pelargoniums have been long appreciated as useful plants on account of their graceful drooping habit, which renders them well adapted for suspending in baskets and as marginal plants for large or rustic vases, &c. But it is possibly among the hybrid varieties that really useful sorts for the purpose of bedding are to be found, and the ornamental and rich wax-like foliage of these plants compensates for an admitted paucity of bloom which characterises some of the kinds.

I may remark, *en passant*, that it is very interesting to observe the extraordinary vigorous growth of some hybrids between the ivy-leaved and zonal sections. One of these has covered a large portion of the back wall of a greenhouse here in a few months. Indeed, I am unacquainted with any other variety of plant which could have covered a like space in so short a time, and it does not appear to lose any of its vigour by being increased from cuttings. At a short distance it might well be mistaken for the Irish ivy. Its flowers are large and of a soft rose colour, but few and far between.

Very little difficulty is experienced in increasing these plants, which are usually struck here early in August in the open air. Four cuttings are placed in a four-inch pot of light, sandy soil, and in these pots they usually remain until the bedding-out season arrives, when they are merely shaken out of the pots with little or no soil adhering to their roots, and at once planted thickly in the beds, watering well as the work proceeds. This watering is occasionally repeated, if the weather proves dry, until the plants have fairly established themselves.

Nearly all varieties of Ivy-leaved Pelargoniums may be said to be good bedding plants; but I will name a few sorts which I have proved to be remarkably useful in that way, viz.:—Crimson Ivy-leaved, an old variety and an excellent bedder; Delicatum, a good bedder, with blush or light-rose coloured flowers; Duke of Edinburgh, fine variegated foliage, trailing habit, of robust growth; L'Elegante, leaves with neat white margins, which frequently become crimson, and when seen in a bed have a most striking effect, which is most telling when the flowers are picked off; Silver Gem, with foliage margined white and flowers lilac-coloured, makes a fine bed or margin to one of large dimensions; Bridal Wreath, this is a hybrid variety, with well-formed pure-white flowers, and very pretty foliage, the young leaves at first being nearly white, changing to bright green when fully developed. To form a white bed I know of no plant that surpasses this variety. Lady Edith, Willsii, and Willsii roseum, are exceedingly beautiful hybrid varieties, and very effective and beautiful bedding plants when grown in a comparatively light soil. For these, I believe, we are indebted to Mr. J. Wills, of South Kensington.

Culford.

F. GRIEVE.

VEGETATION IN THE CHANNEL ISLANDS.

PROBABLY there are few spots of similar extent where there are more gardens and a more general taste for gardening than in the Channel Islands. The colours of the flowers appear to be intensified by some peculiarity of soil and climate. The blue convolvulus and blue lobelia, and the scarlet geraniums, are several shades deeper in colour than they are on our coast. The Hydrangea, which generally has a pink blossom here, is usually blue in these islands, but the colour is not constant, and the plant may sometimes be observed changing its hue, one colour apparently struggling with the other.

Among sub-tropical plants we noticed several tender varieties of acacia, the Australian gum tree (Eucalyptus), the orange and the olive (both fruiting in the open ground), Cestrum aurantiacum, the Veronica Andersonii and other varieties of the same pretty flowering shrub, and myrtles, which grow to a large size and blossom freely. The fig overtops the cottage roofs, and its fruit is the earliest that reaches the London market. The geranium and heliotrope stand the winter unprotected, and old plants of these flowers sometimes almost cover the cottage walls. The Magnolia grandiflora grows into a small timber tree; one in the garden of Mr. Carey, of Woodlands, in Guernsey, is 45 feet in height, and is said to be the largest in Europe. In the same garden is a cork tree with the trunk as big as the body of a large man, producing cork in thick layers, which has been freely sliced off by numerous visitors. The single red and white camellia grows everywhere; we saw one covering a wall 30 feet by 16 feet. One of the prettiest of evergreen shrubs, the Escallonia macrantha, ornaments almost every garden with its bright green shining leaves, and blossoms until Christmas. An evergreen Eunomous (*E. japonicus*) is also common; and the evergreen oak is a remarkable feature in the arboriculture of Jersey and Guernsey.

In many gardens the magnificent clumps of aloes decorating the lawn or grounds would fill a large conservatory. They blossom at the age of twenty or thirty years. At St. Peter's we saw an aloe (*Agave americana*), growing in the front garden of one of the houses, which had produced a magnificent stem, loaded with blossoms. The following year the stem stood erect, measuring about 35 feet in height, and the plant, fated to die after the effort of blossoming, was then apparently withering. The aloes are among the plants that help to give the little islands a southern aspect. H. NEWLANDS.

LAW NOTES.

Poisoning Cats.—The *Birmingham Post* says:—"A gentleman evidently of strong family antipathies, residing in Edgbaston, was summoned by his next-door neighbour to the Birmingham Police-court for having exposed poisoned food in his garden for the destruction of life, contrary to the statute. The particular offence alleged was that the defendant had placed upon his lawn two pieces of fish covered with strichnine, which had been the cause of death of two favourite cats of the plaintiff. Defendant's answer was, in substance, an acknowledgment of the poisoning, but a denial of its illegality, on the ground that the land upon which the poisoned fish was laid was enclosed. It seems that, although the statute is very severe upon persons who sow or expose poisoned grain or seed, or place poisoned meat in fields and open lands, the prohibition does not extend to enclosed gardens. The bench had no alternative but to decide in favour of the defendant and dismiss the summons."

Damaging a Crop by Chemical Fumes.—*Hindspeth v. Patterson & Co.*—This was an action brought to recover £39 18s., the amount of damage alleged to have been done to crops on the plaintiff's land by poisonous fumes from the defendants' works. The plaintiff saw the fumes settle upon and damage the crops on several days during May. The deficiency in quantity was estimated at £25 11s. 6d., and the deterioration in quality at £14 7s. 3d.; total damage, £39 18s. 9d. The defendants said that damage was sometimes done to crops by vapours from alkali works, and the tenants properly got compensation; but in this case they denied that any damage was done. Test papers did not change colour, showing that no acid vapours were present, a fact which was also corroborated by others. The jury nevertheless returned a verdict for the plaintiff—damages, £20.

The Law in Reference to Fruitmen's Baskets.—Mr. Shrubsole, a fruit-grower at Sittingbourne, Kent, sued Messrs. Skinner, salesmen in Covent Garden, in the Westminster County Court, the other day, for compensation for baskets that had not been returned to him. Messrs. Skinner stated that their expenses for baskets were nearly £1,000 a year, that their losses were annually about half that sum, and that it was not the custom for growers to charge for baskets not returned, as they were frequently lost and mixed with others, as in the present instance. It was, in short, proved that the custom of the market was, that baskets were trusted to the buyers without money being left upon them. The judge considered Messrs. Skinner clearly entitled to a verdict, as the baskets appeared to him to be nothing more in relative value than the paper bags or fancy boxes used by confectioners, haberdashers, or others, to send their goods home in. He, therefore, gave judgment for the defendants, and, on application, allowed the full costs of their solicitor and of five witnesses.

The Law as to Landowners and Footpaths.—In the Court of Queen's Bench a case (The Vestry of St. Mary, Newington, v. James) of some importance to owners of property was lately decided. The defendant had applied to the vestry for permission to remove some flag pavement in front of his premises, and replace it by pebbles suited to bear heavy burdens. This having been refused, his waggon was driven over the footway, and broke the flags. Proceedings were therewith taken against him under the Highway Act, and the magistrate having refused to convict, the vestry carried the case to the Queen's Bench. Their appeal was rejected, however, Mr. Justice Mellor, who delivered the judgment of the court, saying:—"At common law—or under the statutes—an owner who dedicated the soil to the public use as a footway parted with no other right than the right of traffic for the public. If this were not so, the owner of an estate having dedicated a portion of it to the purpose of a roadway, raised on both sides for the purpose of a footway, would, by lapse of time, be precluded from opening a new gateway into his land from the roadway, and thus would be prevented from putting the premises to any new use. But such was not the law. No doubt the owner could not so derogate from his grant as to obstruct or interfere with the full and free right of passage; but that was all that he was bound to allow; and, subject to the public right of passage, the rights of the owner were left unimpaired."

New Entrances into Old Thoroughfares.—In the case of Bean v. Thomas, lately tried in the Court of Queen's Bench, Westminster, a question of great importance to the owners of land abutting on a public way was raised, namely, whether they have a right to open doors or gates into it. The parties to the action are neighbours, and the place in dispute is a narrow lane running between their land. This lane had been used by the public for half a century, people going up and down it, surely, as the place was in a rural district. The defendant had lately opened a gate from his land into the lane, and the plaintiff, as the owner of the soil, complained of this as an unlawful encroachment. The case was tried at the last Surrey Assizes, before Baron Bramwell, and it was found that the plaintiff was the owner of the soil in the lane, and that the lane was a public highway. On this the learned baron directed a verdict for the defendant, holding that anyone whose land abuts on a highway has a right to open gates or doors into it at pleasure. Mr. J. Brown, Q.C., moved, on the part of the plaintiff, to set aside this verdict, arguing at some length that the public were limited in their right to use the lane, and could only go up and down from end to end, and that the defendant had no greater right than anyone else. The court, however, were from the first quite clear that this view could not be sustained. Suppose, said the Lord Chief Justice, that I dropped in the lane from a balloon, or took my horse over it in hunting, should I be a trespasser? It was manifest, and, indeed it was admitted, that this would be so, according to the contention of the plaintiff; and surely, said the Lord Chief Justice, this would be contrary to common sense. Is a gentleman a trespasser who jumps over his park wall into the road? There was no trace here of any limitation of the ordinary right of the public on a highway, and that was to go over it in any direction, and to open gates into it at pleasure. This was too clear to be disputed. The rest of the court concurred, and the application was refused.

THE HOUSEHOLD.

SALADS AND SALAD-MAKING.

There are few subjects upon which more nonsense is customarily written than those of salads and salad-making, and it arises principally from a slavish imitation of our great cooks, and, to a great extent, from the improper selection of materials. Taking lettuce as the staple article, where, in point of flavour, is there one that is fit to compare with the varieties of the old Brown or Bath Cos, and next to them the Paris White and Green Cos? To those who like soft lettuces, Tom Thumb, Tennis Ball, Neapolitan, and the like are good enough, but not one of them has the true lettuce flavour. I like them occasionally for a change; but not one of them can be compared with a well-grown Cos Lettuce. For such a heterodox assertion I fear I shall be voted vulgar; but oil, though it be the best Lucca, is distasteful to me, and a delicate salad I would rather have a tablespoonful or two of pure sweet cream than oil. Give me this: a dessert-spoonful of perfectly mashed potato, salt, sugar, mustard, and vinegar to taste; add to these, if you like them, a drop or two of chilli or eschalot vinegar, and you have a salad mixture fit for a queen. Salads I like pure and simple, and would suit them to the joint with which they are to be eaten. If it is lamb, chop a sprig or two of mint quite fine; and if for cold beef or veal, a few young onions treated in the same manner will not be objectionable. At this season get perfectly blanched endive, the broad-leaved Batavian being the best, a stick or two of celery, some beet, and two or three well-boiled mild onions. Try the same mixture, and you will have little cause for complaint.

No sympathy with a great variety of articles in a salad, I say, gon, chervil, lambs lettuce, radishes, &c. The nutty impion is a great improvement; but radishes and cucumber place in salads. I do not even admire "lobster salad"—at the vile compound which one gets served up at public and many private ones, and which in many cases is an

indigestible mess. Give me the tail or claws of a nice fresh lobster, with a spoonful or so of the spawn: let me have the ingredients before noted, some well-blanchend lettuce or endive, and the preparation of a salad to eat with lobster will not be a work of many seconds, though infinitely superior to the kind, which some compound. As a great admirer of vegetables of all kinds, I like them in their pristine and simple purity, and I would rather have a salad in its simple form, than the best mixture which Francatelli himself could invent. I like these things as sauce to viands, not as viands themselves. A. P.

[We fear our correspondent belongs to the *gourmand* rather than the *gourmet* section of salad-eaters.]

NOTES AND QUESTIONS ON THE HOUSEHOLD.

"Cole Slaw."—The German population here (United States), as in the great Fatherland, are fond of what they call "sour krouft," which is no doubt wholesome, but it would not be appreciated by English people. In another form, however, viz., that of "cole slaw," cabbage is very relishing; this is simply the nice white hearts of cabbage sliced fine by machinery, seasoned with oil and vinegar, and eaten as a salad. Some may exclaim, What taste! I say try it, either alone or mixed with other winter salading; it is not amiss, too, mixed with sliced raw tomato; but in America "cole slaw," always accompanies raw oysters—an excellent combination. Oysters are cheap here, and the quantity of cabbages consumed in New York along with them, and in other ways, would be a matter of surprise to Englishmen.—JAMES TAPLIN, South Amboy, New Jersey, United States.—[We have never tasted in any country a more agreeable salad than "cole slaw" in America, when properly made.]

Carrot Pudding.—Half-pound each of plums and currants picked and stoned, half-pound finely-chopped beef suet, three-quarters of a pound of bread crumbs, half-pound each of carrots and potatoes (raw) when scraped and grated, quarter-pound of fine moist sugar, a little finely-cut lemon-peel (or if preferred, two ounces of candied peel), spice to taste, a teaspoonful of salt. Very little liquid is required to form the right consistency, as the moisture from the vegetables is nearly sufficient. What more is wanted should be milk. Boil in a basin or mould from four to five hours. Serve with or without brandy sauce. This is a very nice and inexpensive pudding, no eggs being used.

White Winter Radishes.—A Russian prince, last October, after complimenting me with reference to the salads supplied by my employer's table, remarked, "Only one thing you require to make your salads perfection." I naturally inquired what that was, when he replied, "The Russian white winter radish." Of this he promised to send me a packet of seed, and if he does, I will grow it and let you know the results.—R. GILBERT, Burghley.

Poisoned by Rhubarb.—Mrs. Lucy Snook, aged fifty, wife of Isaac Snook, residing between Oneida and Durhamville, died from the effects of eating for greens the leaves of rhubarb or pie plant, of which she was very fond, and from the poisonous effects of which she suffered for nearly three weeks previous to her death. The stalks of the pie plant, when peeled of its outer covering, is not injurious when used for food; but the leaves are poisonous, and should never be eaten.—*American Paper*.

Nettles for Food.—One of the most neglected, and certainly one of the most common of our British plants, is the stinging nettle (*Urtica dioica*). Three species are known in this country, but the one mentioned is perhaps the most common. Many country people believe in nettle tea as a useful spring medicine, and not a few boil and eat them as a green vegetable. They were in former times grown in Scotland as a pot-herb, and if forced and blanched by earthing up in a similar manner to asparagus and seakale, the young tops make a very good dish. In Belgium, Germany, and other parts of continental Europe, nettles are much more generally used as food than they are with us.—*Food Journal*.

MODES OF COOKING BRUSSELS SPROUTS.

SAUTES AT BEURRE.—Trim them neatly, and wash them in several waters; put them to boil in plenty of salted water, and, when almost done, strain them, and dry them in a cloth; put them in a sauceman with a large piece of butter, pepper, salt, and grated nutmeg to taste. Toss them gently on the fire until they are quite cooked.

A LA CREME.—Boil them as above. Melt a piece of butter in a sauceman with a pinch of flour; add pepper, salt, grated nutmeg, and a small quantity of cream or milk; put in the sprouts, and keep them simering till they are ready.

AU JUS.—Parboil them only in salted water; then, having drained and dried them, put them to finish cooking in a sauceman with some well-flavoured clear gravy, adding, pepper, salt, and grated nutmeg to taste.

A LA MAITRE D'HOTEL.—Having nearly boiled the sprouts, melt a piece of butter in a sauceman, toss them in this until done, add some minced parsley, a sprinkling of pepper and salt, and the jui' lemon.

A LA LYONNAISE.—Mince a small quantity of onions or them, light brown in butter, then add the sprouts re-pepper and salt to taste.

SAMUEL BROOME'S MEMORIAL.

All lovers of flowers who live in London, or who have been frequent visitors to the central part of our great metropolis, will have heard of the work, if not of the name, of Samuel Broome. For thirty-eight years, as gardener to the Honourable Society of the Inner Temple, it was his living task to contribute to the pleasure and innocent enjoyment of thousands of those who made the Temple Gardens their frequent resort, and especially to the delight of the children of this great city, who found in that ancient pleasure-ground, not only a playground, but a charming retreat from the crowded streets.

Samuel Broome, though a famous grower of the chrysanthemum, was much more estimable as a man, from his great natural kindness and good-natured frankness of disposition. We have therefore great pleasure in recording the fact that some of his many friends have subscribed to erect a monument to his memory above his last resting-place in Nunhead Cemetery. Of this monument we now furnish an illustration. It consists of a column of Aberdeen granite eleven feet in height, standing on a double platform, and is embellished by a wreath of chrysanthemums in white marble.

Samuel Broome's Monument in Nunhead Cemetery.

No man in his sphere was more deservedly popular or better known than Sam Broome, as might be gleaned from the numerous regretful notices of his death in the press of all rank. We may conclude in the words of *Punch* :—

"Never was simple man more glad than thou,

Never were gentler pride and joy than thine—

Pleased to see pleas'd crowds round thy *pompons* bow,

Children, maids, barristers of parchment brow,

Who rarely noticed sun's or blossom's shine.

"Along Thames bank thy blooms stood brave and bold,
The brighter for the brick and mortar round :

And if thy flowers were flowers of gold,

So innocent none grew from Temple mould,

None so enriched, yet cumbered not, the ground.

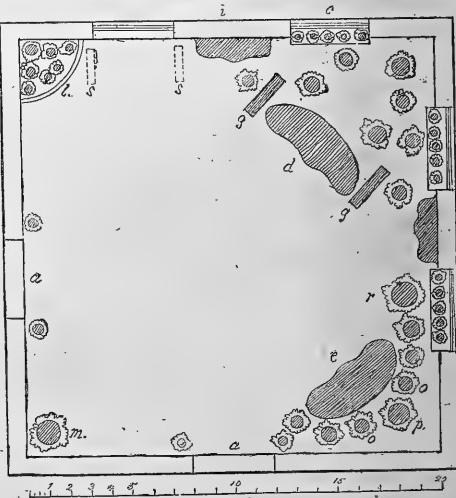

"How oft, when Autumn daylight in the West
Was blended with the City's lurid flare,
Pale cheeks and aching brows thy flowers have blest,
That breathed a breath of Nature and her rest,
Thy o'er-wearied with law's cark and care,
To thee, kind, honest, old SAM BROOME."

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 128.)

The task is more difficult, when, along with a suitable arrangement for culture, the decoration of the apartment is also aimed at. The usual positions selected for this purpose are the corners of the room, and the parts of the walls between the windows. These last positions are generally those which, from considerations of space, people devote to plants when there is not sufficient room for them in the rest of the apartment, but for the culture of plants they are most unsuitable positions, because they are either too far from the light, or the light from the windows cannot fall directly on them. Corners which are opposite the windows receive, at least, the light directly, and so are far more favourable for the culture of plants than, for example, the corners of the wall in which the windows are placed, or the parts of the wall between the windows, which, although nearer to the light, do not receive it directly. Therefore, when the culture of plants is confined to the room itself, and the specimens cannot from time to time be removed to the plant-house, these positions should either not be furnished with plants, or a selection should only be made from the few kinds

Plan of Room with Plants.

which succeed in rooms even when they receive but little direct light, as, for example, *Plectogyne variegata*. (which cannot be surpassed in this respect), some of the taller kinds of *Anthurium*, with long and broad leaves, and many varieties of ivy. In the immediate vicinity of the fire-place, no plants will last long.

Where it is desired to decorate a room permanently with handsome hot-house foliage-plants, the arrangement must be such that all the plants may be exposed to the direct light from the windows and yet be placed not too far from the fire-place. A few creepers that will thrive in the shade, as the ivies and *Cissus antarctica*, the plants before-mentioned, with a judicious selection and arrangement of the furniture must then help to fill up the plan. On festive occasions, when a greater number of persons than usual crowd one's rooms, any plants in the way can be removed for twenty-four hours without injury to the unoccupied corners of the room, to serve to decorate for the occasion. But let me seduced into making the experiment in winter cold staircases with plants placed around here for a short time. If he does so he will lose, if

the labour and trouble of many years. Plants which occupy rather unfavourable positions should not be allowed to remain there always, but should change places from time to time with the specimens which are better placed.

In order to illustrate the foregoing general principles of arrangement for permanent decoration, I will cite a special case, namely, that of my own dwelling-house, in which I have cultivated most kinds of ornamental plants without removing them into the open air for about eight years. The only favourable positions in my house are the rooms which face the south. Moreover, the double windows are kept fast closed during the whole winter, and the ventilation is not very perfect; the rooms are heated by sheet-iron stoves, and dust, unfortunately, always abounds in immense quantities, so that when the long, cold winter of St. Petersburg, with its short, dark days, is added to the foregoing conditions, they cannot be spoken of as very favourable to the culture of plants in rooms.

The room which, by preference, has by the ornamental arrangement of the plants grown in it been converted, so far as a room can be, into a winter garden, is a corner room with two windows to the south and two to the east. One of the east windows, on account of a balcony in front, is too dark for the culture of plants.

The preceding figure shows the ground-plan of this room, the positions of the plants being indicated by the dark, round marks; *a a* are the doors; *b f* the south windows; *c* the one east window which is suited for plants; *d e* two sofas placed

To these instructions on the arrangement of ornamental plants for permanent decoration, as exemplified in this special case, we shall add a few remarks. The flower-stand which now occupies the corner *l*, was at first placed in the south-east corner, between the windows *f* and *c*. Here, although standing between two windows, it received no direct light, so that all the plants had to be very soon removed to a more favourable position. In the corner *l*, the flower-stand was for some years adorned with a large specimen of *Anthurium Luschnathianum*, in front of which stood some *Plectogyne*s. On the outside are placed *Begonias* with variegated leaves, and, during the winter, *Marautas*, which are brought in from the plant-house. For the permanent decoration of the front edge, the best subject is ivy, allowed to grow with its shoots hanging down. In the corner behind the sofa *a*, before the present arrangement, some specimens of *Musa* were at first placed; these, however, had always to be removed after a few months. After this a large specimen of *Cinnamomum Reinwardtii* (a plant particularly adapted for room culture), was placed there. This stood for more than a year, but by degrees all the shoots which got into the dark corner died off, while the rest struggled towards the window and flourished luxuriantly for a long time. The arrangement shown above was then fixed upon. At *p* stands a strong specimen of *Monstera deliciosa* (*M. Lennea* or *Philodendron pertusum*), which, in this position, has thriven and grown well for several years. At *o o* are two *Plectogyne*s, on stands. At *r*, next to the window, there has stood for six years a fine specimen of the coffee tree which never grows so well in the plant-house as it does here. This plant was covered from top to bottom with dark green leaves, nine inches long by three inches broad, but at last had, unfortunately, to be removed, as it grew too large and made the room too dark.

When the interior of the room was not likely to be much crowded by company the plants behind the sofas were moved close up against the wall, and the sofas, together with the ivy canopy, moved back within easy reach. It will be understood that the foregoing account is not given to restrict the amateur to an imitation of this arrangement. The modes of ornamental arrangement are as manifold as are individual tastes. It is rather intended to show on what principles successful culture may be combined with tasteful arrangement.—*From the German of Dr. Regel.*

(To be continued.)

NOTES AND QUESTIONS ON GARDEN STRUCTURES:

Boilers.—I was looking at Mr. Weeks's advertisement, about his new boiler, in your second number, in which he says that the boiler is indestructible, and that either half of this boiler may be worked independent of the other, and I was wondering what he meant, because I remember that the iron cement that these boilers are joined with always comes out if the boiler gets red-hot. Well, then, if either half be worked by itself, what must become of the other half? If the water is turned off from that half, and it is drained dry, then the fire will make it red-hot, and so spoil it. But if the water is left in it, without going round the pipes, it will soon burst and destroy everything near it, including the other half of the boiler.—*ALFRED DAWSON, The Cedars, Chiswick.*

How to Make an Ice Stack.—I am anxious as soon as we have a return of frost to make an ice stack, or ice house, on a very cheap scale. If any of your readers have had experience in making them, I will be much obliged by getting any hints as to how it ought to be done.—A. H. M.—[A correspondent, having asked some time since for instructions on making an ice house, was thus answered by another subscriber:—"If he will adopt the following plan for a 'stack,' he may save himself the expense and trouble of a house. On a slope of ground (turf, and facing the north if possible), sufficient for water to run off, make a cone-shaped heap of ice broken into pieces; over this put two or three inches of sawdust, cover that with a layer of dead leaves, and over these put some loose straw (not thatch) to prevent the leaves from blowing about. I had one made last winter as above; it was thirty feet diameter at the base, about twenty feet high, and took seventy one-horse cartloads of ice. I have at this date (Aug. 27th) enough ice left for six weeks' or two months' consumption, notwithstanding the intense and continued heat of the summer, and the stack having been in constant use since July 24th. There must be no artificial drainage nor foundation." In reply to a question, he added that he found no trouble from the straw being blown about if attended to now and then; but that small boughs might be laid on the straw, or anything which would not prevent the covering falling as the ice decreases.—ED. FIELD.]

Sofa Arbour.

across the south corners of the room. Of these, *d* is so placed that its back is in a line with the outer corners of the two windows *f* and *c*, so as to obtain a good deal of room for plants between the two windows; *g g* are two boxes beside the sofa, in which ivy is planted and trained on a trellis, so as to form a canopy over the sofa. In the windows, and around the sofas stand the ornamental plants which have been grown in the room, and which are pleasingly reflected in the mirrors at *i i*.

The south-west corner, although only lighted by one window *b*, nevertheless contributes its share to the general effect. The sofa here is placed just so far from the corner that the space between them may be sufficiently lighted from the window *B*, and ornamental plants are arranged around it. Immediately behind this sofa, and near the doors *a a*, it was necessary to place those plants which have greatest powers of endurance, as these are rather unfavourable positions.

As for the rest of the room, the corner *l* is embellished with a flower-stand containing hardy plants, and both sides of the doors *a a* are adorned with festoons of ivy. No plants are placed near the stove *m*, and the position of the tables in front of the sofas, of the chairs, and other furniture, has not been noticed.

Heating a Small Greenhouse.—I have found Walker's the best stove for cheapness in its consumption of fuel, &c.; it is easily managed, will keep in ten or twelve hours without difficulty—a great desideratum. The chief points to be observed are: To see the cylinder is full the last thing before you retire to rest; to have the coke small and dry, not too small. The draught is regulated by the drawers underneath, assisted by a damper in the pipe which acts as a chimney. All my plants were kept last severe winter in a good state of preservation—I lost none—and this year everything seems promising. I never use the fire or artificial heat when I can avoid it, which saves the stove. Gardeners do not recommend stoves; but for amateurs, whose means and accommodation are limited, I know of no heating apparatus so cheap or successful as the one mentioned above.—*An Amateur Gardener in the "Field."*

Site for a House.—Abundant access of fresh air is of great importance to health in a residence; unnecessary exposure to wind being at the same time to be avoided. Hence to place a residence in the centre of a close array of trees is not desirable; not only is the access of air, light, and heat prevented, but there is always a tendency induced to dampness in the house. In an open, airy, and well drained situation, the effects of even long-continued wet are soon dispelled; but when all sides of a house are surrounded closely by trees, an opposite result is induced, and in comparatively dry situations many evils of a damp one ultimately ensue. One of our earliest English writers on building, Thomas Fuller (1633), speaking of the choice of situation for a new structure, says: "Chiefly choose a wholesome air, for air is a dish one feeds on every minute, and therefore it need be good. Wherefore, great men (who may build where they please, as poor men where they can) if herein they prefer their profit above their health, I refer them to their physicians to make them pay for it accordingly."—*The Englishman's House.*

SOCIETIES, EXHIBITIONS, ETC.

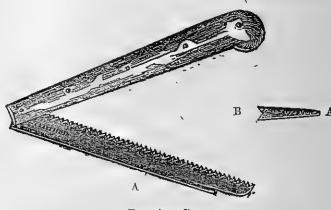

Horticultural Club.—The annual meeting of this club took place on Wednesday evening last, at Anderton's Hotel, Fleet Street. The Rev. Mr. Reynolds Hole was in the chair, and the proceedings were of the most pleasing and congenial kind.

Royal Horticultural Society, Jan. 17th.—The British gardener and British glasshouses have conquered, to some extent, our fierce old British winter. Shows are beginning now to look almost as attractive in winter as in summer. Indeed, more so, for those lovely Cyclamens, which skilful gardeners are rapidly making the most beautiful of all winter flowers, seem far lovelier now than when spring comes with her numerous floral train, and the Orchids, Lilies of the Valley, Primroses, and numerous other flowers of the season (in gardens), look at their best under a gloomy sky. Last Wednesday was most inclement—a wet gale blowing all day—yet the little exposition at Kensington was full of interest and beauty. A number of new varieties of Chinese Primroses, mostly double sorts, flaked and spotted, were shown by Messrs. E. G. Henderson, long known for their success with these most interesting plants. These were deservedly awarded certificates, being quite a novel deviation from the old colours. Their names were, Princess of Wales, very double, white; Exquisite, delicate peach; Magenta King, rose; and Emperor, one of the Fern-leaved class, with very double, lilac flowers. Ivies in pots were a conspicuous feature of the meeting, Messrs. Lane obtaining first prize. Their specimens were trained in a narrowly-pyramidal fashion, which seemed to suit the Ivies better than any other form of support. We, however, think that Ivies should not be trained over a thin trellis of any kind, but shown in baskets, and allowed to trail gracefully down. We were particularly pleased with *Hedera argentea rubra*, in Messrs. Lane's collection. Among Conifers in pots, one of the loveliest and most graceful objects we have ever seen was a noble specimen belonging to Mr. Standish, of *Retinospora filifera*. It was like a green fountain; but the general surface was broken up in the most picturesque manner. Most remarkable, too, was a specimen of *Retinospora obtusa pendula*, almost a weeping subject, of great and peculiar beauty when well developed. What gains for our gardens are these lovely dwarf trees with a more elegant form than that of ferns themselves, hardy as British oaks, and in the full flush of verdure in mid-winter! Some Cyclamens with wide silvered bands round the leaves were shown by Mr. Wiggins. We shall soon have quite a number of forms of the Persian Cyclamen. There were many Orchids shown, the most remarkable being *Odontoglossum Denisoniae*, a large and very beautiful species, and the exquisite lilac and ivory *Phalaenopsis Porteana*. Many plants of *Bouvardia jasminoides*, in fine bloom, were shown by Mr. Standish. It is a lovely flower for winter cutting. To bloom well now it is planted out in shallow cold pits in summer, the plants being pinched to keep them dwarf and flowerless. In autumn they are potted. In winter and early spring they are introduced to the forcing-house or warm pit quite near the glass. Among vegetables, the most remarkable things were some giant garlic, "Naples Giant," the clusters of bulbs of which were as large as a pair of big clenched fists. Prizes were offered for the best three dishes of Kitchen Apples, also for the best three dishes of Kitchen Pears. For Apples Mr. Parsons, gardener to R. Attonborough, Esq., Acton Green, was first with excellent fruit of Blenheim, Pippin, Golden Noble, and Dumelow's Seedling. For Pears Mr. Miles was first with Uvedale's St. Germain, Catilao, and Vireo of Windish. Mr. Wilson, gardener to Earl Portescu, Castle Hill, South Molton, sent two remarkably handsome and large specimens of Charlotte Rothschild Pines, weighing 13*1/2* lbs., from plants seventeen months old. They were awarded a cultural commendation. A report on the system of keeping Grapes in bottles was read by Mr. Moore, gardener to Earl Brownlow, at Belton, Lincolnshire.

THE PROPAGATOR.

THE ART OF GRAFTING. (Continued from page 157.)

THE SAW.—Hand-saws, with either a fixed or closing blade, are used for cutting strong branches and thick stocks for crown grafting with a tall, or a short stem, and for cutting off the heels of grafts made on the branches of the stock when they are dry or too thick for the pruning-knife or the secateur. When a strong branch is to be sawn, the heavy branchlets above the place of incision should first be removed; this will render it easier to work the saw, and the bark of the trunk will not be so likely to be injured. Moreover, the operator slackens the movement of his arm when the branch is nearly

Pruning-Saw.

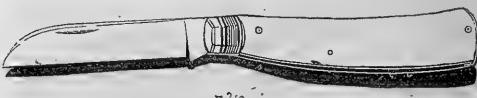

sawn through; it is often even prudent to cease sawing altogether then, and finish the amputation with the pruning-knife, holding with the other hand the part which is being cut off. Cutlers manufacture saws with a single or a double row of teeth, and with the back of the blade (A) thinner than the toothed part (B). Grafters use excellent saws made of scythe blades, with one row of teeth, and set in the handle at an angle. The saw should never be used on a living tree without dressing and smoothing its marks with the pruning-knife, otherwise the furrows left by the saw will retain moisture on the surface of the wound and retard its healing.

THE PRUNING-KNIFE consists of a handle of wood or horn, either straight or slightly curved, and a blade curved at the end. The point of the blade is more or less prominent. The

French Pruning-Knife (Scopette).

workman becomes so accustomed to a particular shape that he often prefers an old, almost worn-out, knife to a new one of more even form. The pruning-knife is necessary for dressing the wounds caused by the saw or the secateur, for trimming bruised or torn tissues, and for smoothing down a cut so that it may present a level surface, without inequalities, bruises, or splinters. In order to smooth properly, the hand which holds

English Pruning-Knife (Straight-bladed form).

the handle of the tool should have the thumb supported against the branch or stem, while the other hand directs the blade. In the case of a stock of moderate thickness, the shortening of the stem is effected by means of the pruning-knife without having recourse to the saw. The pruning-knife is also employed for cutting up the scions into suitable lengths. If it is preferred to employ a pruning-knife, in cutting and

dressing them finally it will be advisable to have in reserve another finer edged one, and keep the first for heading down cutting-off old stems, and such rough work. Graftors who use the pruning-knife for every operation of grafting should choose a blade not much curved, which will be found very handy when it is required to split the stock. The pruning-knife is also used, after grafting, in shortening those stocks which have not been previously cut, and also for removing the heel of the graft after a year's growth. The handle is held with both hands, and thus the heel is cut off with greater ease. This implement is also useful in trimming thorny trees.

THE BUDDING-KNIFE is a tool with a narrow blade, widening towards the end, and with the point curving backwards. At the end of the handle is a spatula, or small, thin blade of ivory

English Budding-Knife.

which is used for raising the bark. This spatula should not be made of metal, as that would soon be rusted by the sap. The budding-knife is indispensable for bud-grafting, for cut-

French Budding-Knife (*Graffoir*).

ting the scions in branch-grafting, for raising the bark, for grafting under-glass, or cutting ligatures when too tight for the graft, &c.

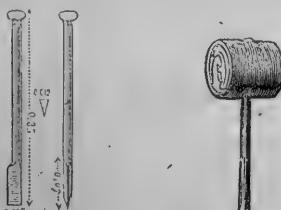

THE GRAFTING-KNIFE.—The handle of this implement is slightly curved in order to facilitate grafting at the surface of the ground; the blade, in form of a comma, or drop, is useful for splitting stocks intended for cleft-grafting when a partial

Grafting-Knife.

cleft is required. A cleft from side to side is obtained by means of a knife with a straight blade, like a table-knife in shape. The handle and back of such a knife should be strong enough to support the blows of the mallet which the operator is sometimes obliged to use in cleaving very thick or hard-wooded stocks.

THE GRAFTING CHISEL has the blade and the handle all in one piece, iron and steel. It has every advantage of solidity and resistance when it is required to cleave strong stems,

Grafting Chisel and Mallet.

either with or without the help of the mallet. When the cleft is made, we can, by half withdrawing the chisel, use it as a lever or wedge to keep the cleft partially open, and facilitate

the introduction of the graft. The chisel used by the vine-growers of the south of France measures fourteen inches in length. The blade is about two and three-quarter inches long.

THE GRAFTING-GOUGE here represented comprises a handle about four inches long, and an iron stem nearly eight inches in length, the upper part of which for about two inches is

Grafting Gouge.

curved inwards, and terminates in a curved gouge, with which the groove to receive the graft is cut. This implement, which is recommended by M. Rose-Charmeux, of Thomery, is useful in grafting by approach.

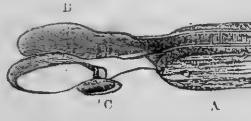

COMBINED GRAFTER.—M. Auguste Rivière, head gardener at the Luxembourg, Paris, is the inventor of this implement, the special use of which is in grafting by incrustation, which will be alluded to further on. The blade has a double purpose: the gouge (B) at the upper end is angular, so as to produce in the stock a wedge-shaped incision. At the bottom of the blade is a similar angular gouge (C), with which the scion is cut into a

Combined Grafter.

triangular wedge, which will fit perfectly into the incision made in the stock, as the two gouges (B and C) are made with the same angle. That at C may be turned the other way, so as to suit a left-handed workman. Between these two parts, the blade is sharp-edged at A, and serves for cutting the scion from its parent tree, or for smoothing the angles, if they have been imperfectly cut by the gouge at C.

THE METRO-GREFFE.—This tool is composed of a double spatula, which is fitted into the handle of an ordinary grafting-knife. Its use is to measure the scion and stock, so as to make them fit exactly in those modes of grafting, in which the two parts are placed in juxtaposition by simple veneering. The handle (D) bears at one end the blade of the grafting-

The Metro-Greffe.

knife which cuts the scion; and at the other end the double spatula, the two parts of which (A and B) are joined by a screw (C). The metro-greffe answers the purpose of a pair of compasses for measuring the back of the bevel of the graft, and then tracing on the stock a corresponding width for the groove which is to receive it.

All these tools are not indispensable in the practice of grafting; but they have each a special use. The last three are intended to facilitate nice and complicated operations in grafting.—*Charles Baltet*.

(To be continued.)

Propagation of Sarracenia.—How is this to be done?—A. D., *Cambidge*.—[All *Sarracenia* may be readily propagated by division of the crowns by means of a sharp knife. Be careful, however, to mutilate as few of the small feeding roots as possible. Pot the crowns thus divided in four or six inch pots, according to their size, using similar material to that recommended for larger plants, and treating them in every way the same.—T. BAINES.]

THE AMATEURS' REMEMBRANCER.*

Flower Garden.—While the weather is comparatively mild and open, finish all kinds of ornamental planting, and bring alterations in the way of ground-work to a close. Prune and tie in hardy wall plants; but not in such a way as to render them stiff or unnecessarily formal. Bedding-out plants, of which there may be a short stock, place near the glass, in a moderately moist, warm house, to encourage growth for early cuttings; but such kinds as there are plenty of, excite as little as possible; on the contrary, give air liberally while the weather is favourable. The season being mild at present, some of the spring flowers are beginning to peep forth. Where such is the case many will like to make the neighbourhood of the beds as neat as possible. Beyond this in well-ordered gardens there is really little or nothing to do in this department, unless ordering seeds and making various preparations for the busy season that will soon be at hand.

In-door Plant Department.—Conservatories keep about 45° at night, allowing a rise of ten or fifteen degrees during the daytime; this will suit both camellias and azaleas, as well as such flowering plants as may have been introduced from the forcing-pit. Tie out and otherwise regulate the shoots of such plants as require that attention, and see that none suffer from want of water. Take care, too, while our light supply is somewhat deficient, that there is no unnecessary crowding. Keep insects in check by means of fumigation and washings with tobacco water. Orange trees, a tribe of plants not well treated about many places, may have what little pruning they require, giving a shift to such as want it, and then well washing them with soap and warm water, syringing them well with clean water afterwards. See that the drainage of plants of this kind is in good condition, and when the days are longer, and they have fairly started into growth, feed them occasionally with clear weak manure water. Those who wish for bushy, well-furnished camellia plants should pinch or rub off the terminal bud of each main shoot. The next beautiful conservatory plant now in bloom is the old Cala *athiopica*. Specimens of it in the warm greenhouse or conservatory should have abundance of water. They will also enjoy weak, clear liquid manure in abundance. The same may be said of the Chinese primulas, of which we have now so many pretty varieties, and which are now coming strongly into bloom. In large establishments, where there is no lack of means or appliances, the following flowers, among others, are now in bloom, or may very soon be looked for:—Camellias, Heaths, Epacris, Azaleas (Indian), Geraniums, Euphorbias, Poinsettias, Justicias, Aphelandras, Epiphylums, Amaryllis, Blethis, Dendrobium, Hyacinths, Narcissus, Cyclamen, Tulips, Zygopetalum, Rhododendrons, Odontoglossum in var., Azaleas (American), Mignonettes, Violets, Lilies, Roses, Pinks, Lily of the Valley, zonal Pelargoniums, Cinerarias, Fuchsias, if now beginning to break, should receive what little pruning they need and be re-potted; use loamy, moderately rich soil for the purpose, with surface-dressings and manure waterings. After growth commences they must have the benefit of the light.

In-door Fruit and Vegetable Department.—Pines ripening fruit keep on the side of dryness, and near the glass. Successions keep growing slowly.—Vines started, grow on steadily, syringing the rods and young leaves, in order to assist them to break regularly.—In early peach houses maintain a temperature of from 50° to 55°, with a rise of five or ten degrees during the day, and shut up another house where required, to succeed that just referred to, giving the roots a good soaking with tepid water.—Figs in pots, if any, may now be pruned back; also tie in and regulate shoots of figs on back walls or trellises, previously washing them with Fowler's Insecticide.—Get dung and leaves mixed and turned once or twice preparatory to putting up beds for early cucumbers.—If not already done, re-pot orchard house trees, and, if exposed, plunge the pots in dry fern or leaves.—Strawberries keep at all times close to the glass, and remember that they dislike much heat; let 60° or so be the maximum, with a free circulation of air. Until they begin to throw up their blossom spikes, nothing suits them better than a pit or mild dung-bed.—Bring on asparagus in pits in a temperature varying from 50° to 60°.—Kidney beans sow in pots, to be set on shelves near the glass.—Potatoes start in boxes, and bring on rhubarb and seakale in the dark gently, so as to prevent its being weakly and drawn.—To enliven in frames give as much air as possible, while the weather keeps mild.—Make up a bed for mushrooms with stable dung and soil previously prepared. Beat firmly and spawn when about lukewarm, afterwards cover with soil, hay, and mats.

Hardy Fruit and Kitchen Garden.—Here, except in places where the autumnal work was neglected, there is as yet little to do; alterations of all kinds, however, the experienced and intelligent gardener will not fear to commence at any time, though he will be much influenced by the state of the ground. Proceed still further with pruning, and where young fruit trees have lately been planted, mulch with rough stable dung. Root-prune dwarf standard apple and pear trees, if they are unfruitful or growing too strongly. This is done by digging a trench round the tree, two or three feet from the stem, according to size, and cutting in the large roots. It is also in some cases found to be a good plan to lift small bush trees every alternate year, to keep them dwarf, and in a fruitful condition. Examine labels on fruit trees, and renew such as are becoming illegible. Rough dig or trench all ground free from crops. To cauliflowers under handlights, give as much air as possible while the weather is mild. Stir the surface soil among growing crops, and make vacancies good where such occur.

* Complete general calendars, written by some of the most able gardeners in the country, are published in THE GARDEN in the first issue in each month.

COVENT GARDEN MARKET.—January 20th.

Flowers.—These still consist of Acacias; Azaleas, both cut and in the shape of small plants; Begonias; Callas; Camellias; Cinerarias; grand examples of Lily of the Valley; Coronilla; Cyclamens in pots in excellent condition; Dentzias; Heaths; Euphorbia *jaquiniflora*; Hyacinths; Tulips; Genista; Geraniums, of various sorts, including those with scented leaves, a class now too much neglected; Christmas Roses; Mignonette; Poinsettias; Primroses, both wild and Chinese; a few cut Roses and berry-bearing plants, such as Ardisia and Solanum.

Prices of Fruit.—Apples, per half sieve, 2s. to 5s.—Cobs, per 100 lbs., 60s. to 65s.—Fibberts, per lb., 8d. to 10d.—Grapes, per lb., 3s. to 8s.—Lemons, per 100, 7s. to 10s.—Spanish Water Melons, each, 2s. to 5s.—Oranges, per 100, 6s. to 10s.—Pears, per dozen, 3s. to 6s.—Pine-apples, per lb., 4s. to 8s.—Pomegranates, each, 4d. to 8d.

Prices of Vegetables.—Artichokes, green, each, 6d. to 8d.—Asparagus, per 100, 8s. to 10s.—Beet, per dozen, 1s. to 2s.—Broccoli, purple, per bundle, 10d. to 1s. 3d.—Brussels Sprouts, per half sieve, 2s. to 3s.—Cabbages, per dozen, 10d. to 1s. 3d.—Capsicums, per 100, 6s. to 12s.—Carrots, per bunch, 5d. to 7d.—Cauliflowers, per dozen, 2s. to 6s.—Celery, per bundle, 1s. to 2s.—Chilies, per 100, 1s. 6d. to 2s.—Cucumbers, each, 1s. to 2s.—French Beans, new, per 100, 3s. to 4s.—Herbs, per bunch, 2d. to 4d.—Horse Radish, per bunch, 3s. to 5s.—Leeks, per bunch, 2d. to 4d.—Lettuces, per score, 1s. 6d. to 9d.—Mushrooms, per bottle, 1s. to 2s. 6d.—Onions, per bunch, 4d. to 9d.—Parsley, per bunch, 2d. to 4d.—Radishes, per bunch, 2d.—Rhubarb, per bunch, 6s. to 12s.—Salsify, per bundle, 9d. to 1s. 3d.—Scorzonera, per bundle, 9d. to 1s. 3d.—Seakale, per punnet, 1s. 6d. to 2s. 6d.—Shallots, per lb., 8d.—Spinach, per bushel, 3s. to 4s.—Tomatoes, per small punnet, 3d. to 6d.—Turnips, per bunch, 8d. to 12d.

The Wholesale Price of Vegetables.—Some little idea may be formed of the necessity of a reform in our greengrocery arrangements by the following passage, which occurs in the report of Mr. H. J. Morgan, on the cultivation by means of sewage irrigation, of the Lodge Farm, Barking, for the year ending August 31st last, which has just been printed. "The average price," says Mr. Morgan, "which our best potatoes last year realized was from £6 to £7 per ton." This year we have obtained no more than £2 to £2 10s. Onions, which sold last year for £4 per acre in the ground, and realized a great deal more by marketing, have this year been sold by us at £28, the highest price I have heard of being £30 per acre. In the autumn of last year cut cabbages (*Collards*) fetched from 1s. to 1s. 3d. per dozen, while this year there has been a difficulty to obtain 3d. and 4d. per dozen, some having even sold 1s. I, as low as 6d. for five dozen. Scarlet-runners, which made 8s., 10s., and 11s. a sieve last year, only reached 3d. and 4d. and 1s., until lately, when they have made 2s. and 2s. 6d. a sieve. Bunching greens have not paid us to market, and we have hitherto fed cattle on them. I have been told by several farmers that they have ploughed in their crops, as it would pay them better to use them as manure than to market them. These differences in price have not at all arisen from differences in quality, as our produce has been, in most cases, as fine and as abundant this year as last. Strange to say," adds Mr. Morgan, with refreshing naivete, "that in the face of all this the retail prices are as high as ever, a cut cabbage ordinarily costing 1s. 1d., and a small dish of beans 4d. and 6d. with everything else in proportion."

Novelties.—We cut the following from the letter of a French gentleman, a member of a well-known firm, respecting the shoals of called novelties that are now being sent out. "Some of your English novelty-mongers are making the question a perfect maze. It takes, for example, six months to know all the new peas of the season, and as much to go through the potatoes and cauliflowers, and then nothing is left for the cucumbers. What if one wishes to know also the new flowers into the bargain? German asters, &c. &c.? Are vegetable shows often held in London? It would, I think, be a better plan, and scarcely more expensive to attend them once or twice in the year than to order and grow fifty new kinds of vegetables every season."

Part I. of THE GARDEN, containing 6 Numbers, and upwards of 80 Illustrations and Plans, is now ready, price 2s., and may be had from all booksellers and newsagents, and at the railway stalls. Post free from the Office, sent flat between boards, 2s. 6d.

Readers who may find it difficult to procure the numbers regularly through the newsagents or booksellers, may have them sent direct from the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance. THE GARDEN is sent to subscribers by Friday evening's post. All the numbers of THE GARDEN may be obtained from the office, and through all booksellers and newsagents.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER.

"This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—Shakespeare.

THE FLOWER-GARDEN

ROSES AND ROSE CULTURE.

BY S. REYNOLDS HOLE.

I RESUME, while the weather is still propitious for the planting of rose trees, my selection of those varieties which cannot disappoint, always providing that they are placed where the rose will grow, that is, in garden soil, which, naturally or artificially, deserves the name, and which is not affected by smoking chimneys, nor "under the shade of melancholy boughs." Soot as a substance is a good manure and a good medicine (for mildew) to roses, but soot in solution is a fatal foe; and, as to shadow, why her majesty the Queen of the Flowers naturally takes umbrage at any inferior denizen of the garden is placed over her royal head.

I have already commended *Gloire de Dijon* and *Maréchal Niel*, from the Tea-scented or rather Noisette roses; *Blairii No. 2*, from the Summer roses; *Souvenir de la Malmaison*, from the Bourbon; and *Alfred Columb* and the *Baronne Rothschild*, from the hybrid perpetual class. My next choice from the latter family is *Baronne Prevost*, and I justify my selection by a little incident which occurred to me at the beginning of the last summer. I was leaving home one morning to transact some business in London, when a parishioner, aware of my movements (in a small village the outgoings, the incomings, and it may be the shortcomings, of the priest are quickly and generally known), asked me to take charge of a few roses which she wished to send to a friend. The petitioner was the wife of our Village Blacksmith. It was meet that, like Venus, wife of Vulcan, she should be associated with roses, and I knew, moreover, of a luxuriant rose tree growing upon the wall of her house, but I was greatly surprised to see the beautiful blooms, some ten or twelve of them, which I was asked to convey to town. Something more than surprised—a *suspicion* sore and subdued—seeing that I had just gone over my large collection and only found some half-dozen *Gloire de Dijon* and two or three *Charles Lawsoni*s on a southern wall. And here was a single rose tree holding its own victoriously. *Athanasius contra mundum!* Something more even than surprised and subdued—ashamed, because I had expelled the same rose tree which produced these flowers from my own garden as not being quite good enough for exhibition. And lo! it took precedence of them all—as I have seen a young farmer, on a rough four-year-old or a bad-tempered screw, lead a field of "pinks" on two-hundred-guinea hunters. The rose in question was the *Baronne Prevost*. It had, it is true, the great advantage of a wall, but it is reliable everywhere for an abundance of its large, fresh, blushing roses. The teacher of my youth, the friend of my manhood, Mr. Rivers, advises that a bed of this variety should be grown wherever it may; at all events, let the young rosarian include in his first order *Baronne Prevost*. It grows best upon its own roots, or on the Manetti stock.

Caroline de Sansal is another old favourite which, though, like the *Baronne*, not quite perfect enough for the rose shows, excels a great number of more symmetrical roses in one most

important quality, i.e., in constitution. There is, indeed, so much of the more delicate "China" blood in our new roses, and they are propagated so rapidly under the forcing system, that we have lost to some extent in vigour what we have gained in beauty. *Caroline*, long acclimated to our English air, is always bonnie, always bountiful, and thrives on standard or on dwarf with equal excellence.

Comte de Nanteuil is another of the ancient noblesse, which may say with Tennyson's "Brook,"—

"New roses come—new roses go,
But I go on for ever!"

for it has seen hundreds of rose trees bloom and die in my garden. Grown upon its own roots or worked' low upon a stock, which is tantamount in the end, because all roses planted below the bud or the graft will send out roots of their own, this variety is a true perpetual, blooming continually from the end of June until rude, pitiless Jack Frost, with icy breath, issues his stern command, "Shut up!" The flowers are as full and as faultless in form as the best, but they lose their colour too rapidly for transmission to our public shows.

General Jacqueminot, again, has far more vitality and power of endurance than most of his more showy but less robust descendants, and never fails, if due consideration be shown, to yield an abundance of those soft, crimson, velvety roses, which on their first appearance in England impressed us rosarians with the firm conviction that at last we had obtained perfection. It thrives best on the Manetti stock.

Two plants of *John Hopper*, which the raiser, Mr. Ward, of Ipswich, kindly sent to me on its introduction, are still flourishing in my rosarium. One of the few grand roses veritably of English birth (the others being *Duke of Edinburgh* and *Miss Ingram*, for I do not believe that *Devoniensis* was of Anglican origin), it is a trustyworthy garden rose, and one of the best for exhibition also, although for the latter purpose, as in most other instances, its glories are developed in their full integrity when first it blooms upon the budded briar or Manetti stock.

(To be continued.)

WILL our champion rose-grower, the Rev. Mr. Reynolds Hole, tell us why that very uncertain beauty, *Souvenir de la Malmaison*, has, as a rule, such an awfully hard heart, and how that is to be softened? A rose might as well not be a rose, if its heart is all "eye"—green or otherwise. I agree that perfect flowers of this variety may be worth a crown apiece. But they are very seldom perfect in many localities. No rose of my acquaintance promises more than this one does and performs less. The outer petals begin to unfold, when—oh! grievous disappointment—there is a riven, a distorted, and, not unfrequently, positively a rotten heart. Under glass it seldom serves us so badly, but out of doors the heart of this variety is so unsatisfactory that we have almost given up growing it. My next question relates to the two forms of *Devoniensis*. I cannot think how Mr. Hole could give the climbing sort precedence over the older variety, and even linger fondly over the rampant runner, dismissing our old *Devoniensis*, with others, in a single line as too tender. *Devoniensis* assuredly is, but only a little more so than *Gloire de Dijon*, and the only one that has stood by it through many winters while other teas perished. As to beauty, it was and is a libel to call this climber by the same name or mention it in the same breath as the queen of all tea roses—yes, and I will add, of all other sorts whatsoever; the true *Devoniensis* is perfectly unique in form, in colour, and in sweetness, for no other rose has the same scent. We often hear the remark made that "we may go further and fare worse," an observation most assuredly true in the case of the climbing *Devoniensis*. It runs further than the old kind, yielding us shoots sometimes six feet long—for the first frost—for it is the tenderest of all tea roses. *Devoniensis* lives here as a standard, with a handful of fern fronds thrust into its crown, but its climbing variety dies on a wall unless thatched over. One more question, and I'll be done. Is a soft soil good for roses? As a rule, I have not found it so. Mr. Hole tells us that the best soil is a mellow loam in which a walking stick disappears to the handle. Is this a figure of speech merely, or is the statement meant to be serious? The roots of the dog rose have been accustomed to endure hardness, and it is doubtful if they will know what to make of a soft root-run a yard deep enriched with pig manure. The enrichment may be all right, but the softness seems questionable. Finally, I must heartily endorse all Mr. Hole says of the *Baronne Rothschild*; she "is lovely" beyond description.

D. T. F.

NOTES AND QUESTIONS ON THE FLOWER-GARDEN.

Alpines.—I wish many others have some difficulty in understanding what is actually meant by this term as applied to plants in cultivation; botanically I apprehend its application to wild plants natural to elevated situations, but very few of them are capable of or worth cultivation. Would you kindly give me a list of some twenty or more of such plants suited for a sandy soil and exposed position on the northern outskirts of Liverpool?—A SUBSCRIBER FROM THE FIRST.—(The term alpine is applied in gardens to those plants, mostly very small, that we obtain from high mountain regions. With them, however, in gardens are associated a good many plants, not strictly alpine subjects, that grow in lowland meadows on rocks and on walls. It should, however, be remembered that many plants that inhabit the lowlands of our latitudes are mountain plants further south. Hundreds of alpine plants are "capable of and well worth cultivation." The following is a list of forty, but there are 300 quite as good that would grow "on a sandy soil and in an exposed position," anywhere in the United Kingdom, without the aid of "rock-work," or any attention, beyond planting in the level ground.)

Acantholimon gluma-	D. neglectus	Primula denticulata
ceum	D. petraeum	P. vulgaris and vars.
AETHIONEAE SAXATILE	D. octopetala	Ranunculus montanus
Anthyllis montana	Erysimum coeruleum	Saponaria ocyoides
Arabis albida	Gentiana aculeata	Saxifraga in var.
Arenaria montana	Gypsophila prostrata	Sedum in var.
Aubrieta in var.	Hutchinsia alpina	Sempervivum in var.
Campanula esculenta	Iberis correaefolia	Silene alpestris
C. carpatica	I. saxatilis	S. Schafae.
C. fragilis	Oxybaphus vernum	Veronica prostrata
C. turbinata	Potentilla procera	V. sativella
Cerastium in var.	Phlox reptans	Viola cornuta
Cyclamen	P. subulata and its white V. lutea	
Dianthus deltoides	var.	

Cheap Roses.—I am surprised that roses on their own roots should not have been long ere this offered at much lower prices than those generally quoted by our great growers, with a view to induce amateurs to cultivate them as bedding plants. I know that under certain treatment roses can be struck as readily as willows. I have myself for several successive years put in some thousands, and can reckon always on ninety-five out of every hundred "taking." I calculate that, with the assistance of two boys, a propagator could in twelve months strike 100,000, and pot them in three-inch pots, so as to be ready for sale, with a medium proportion of glass frames and a propagating house. Let us say £30 annually for glass rent, £100 for propagator and £30 for boys, £100 for pots, £30 for coal, soil, and sundries £24 for new kinds, in all £324. Could not these be offered at three shillings a dozen? that would amount to £1,245; allowing a fourth to remain unsold would leave £934 worth sold, or a profit of £600. Will this induce anyone to take up the matter? Packing and baskets, of course, as usual at the expense of the purchaser. In 1853, when bedding plants became first offered at 2s. 6d. per dozen, many expressed their opinion that the trade would be ruined; but what has been the result? While 1,000 used to be sold, 100,000 are now got rid of. Might the same thing not happen in the case of roses?

Aquatic Flower Blooming in January.—I send you a specimen of an aquatic flower found blowing in a pond in South Devon this week, and, as we cannot find it described in Sowerby, we should be glad if you could help us to its name.—Augusta M. Morris, Courtlands, Newton Abbott, South Devon, Jan. 17.—[The charming and singular flower you send is that of Aponogeton distachyon, a native of the Cape of Good Hope, but hardy in many parts of these Islands. It is, however, but very little known or planted. A small pond in the Royal Botanic Gardens at Edinburgh is covered with its graceful leaves. About London we have noticed it beginning to bloom in March in severe seasons; that it flowers even in January is very remarkable. A Cape aquatic, flowering when all the British species are flowerless and at rest, is a curiosity. In a tank or fountain basin, in the conservatory or greenhouse, it is a comely object in winter, flowering abundantly, and filling the house with its fragrance.—ED. "FIELD."]'

Transplanting Sweet Peas.—Earlier late last spring we sowed a row of a particular variety of Sweet Peas across our garden, and, as far as the floricultural and horticultural departments, and on the second morning after they had been sown we found that the earth had been much disturbed about them, and that scarcely a seed was left. The following morning, as early as three o'clock, we found wood-pigeons diligently at work unearthing and devouring any seeds that had been left on the day previous. No time was to be lost, the seeds being so tiny, in re-sowing, and this time we took the precaution to cover them with a herring-nail, hoping that they would not be allowed to grow undisturbed. Vain thought! the sparrow had then learned to fly, and once above ground sparrows took advantage of the dilapidated state of our nail, and hopping in various holes picked, pulled up, and destroyed dozens, ay, hundreds, of the young plants. An attempt was made to make the net-sparrow-proof, but somehow or other they managed to get in, notwithstanding the efforts, and it seems only by means of scrawcrowing that we succeeded in getting the plants beyond the reach of our winged enemies. At various points the plants were so tall, indeed, that no herring-nail could ever have a creditable hedge. What was to be done? Could we transplant Sweet Peas? We had about half a yard or more of first-rate plants from the first sowing that had escaped the pigeons, and these we forthwith transplanted into the blanks and thin parts of the second sown line, watering them copiously, and shading them from the sun for a few days with a mat, supported on sticks; they thrived well, nor did their younger brethren get up to them till all had attained their full growth.—B. and E., Coldstream.

THE FRUIT-GARDEN

TREATMENT OF WALL TREES.

I QUITE agree with your correspondent "W." (p. 176), that the treatment of wall trees generally throughout the country is not equal to what it was in years past. This, however, more especially applies to the cultivation of peaches and nectarines, and may in some measure be connected with cheap glass, which affords greater certainty of securing crops than open walls. Indeed, it has now become a question whether the cultivation of these fruits ought not to be wholly given up on open walls. It is, however, for open walls which I plead; and I always maintain that if trees on these received anything like the attention bestowed on those grown under glass, the results would be a great deal more satisfactory than they frequently are. What, for example, are the facts? Every attention is bestowed upon the occupants of the peach house; insects are kept in check; the trees are regularly syringed overhead, and have copious waterings at the roots throughout the growing season. In fact, every attention they require is paid them; whilst with their less fortunate neighbours outside the case is just reversed. They are either not half protected from spring frosts, or are half smothered; numbers of their first leaves are allowed to curl and turn yellow before any attempt is made to free them from insects; their fruit is not thinned until it has grown to double the size it ought to have attained before removal, or it is insufficiently thinned. Even where all these matters are properly attended to, one fatal error is not unfrequently committed, and that is, insufficiency of water at the roots during the growing season. No matter what attention is given in other ways, if this is not attended to, failure is certain to follow in the shape of immature wood bearing flowers imperfectly formed, and destitute of strength to resist the slightest frost, large branches continually dying off, &c.

In short, after years of attentive observation, I have come to the conclusion that, to an insufficiency of water more than to all other causes put together is attributable the failure in peach and nectarine crops, and premature decay of large quantities of trees throughout the country. The principal wall devoted here to peach culture is not more than eighty yards long; yet, during dry weather in summer, I give the border not less than five hundred gallons of water a week, keeping the roots well mulched. The result is, the trees mature very heavy crops of fine fruit; and although many of them are old, their general condition keeps improving. As to the large fruit-trees of other kinds that "W." appears to like, they are all very well for cider orchards or fruit-growers for market; but they are a mistake in private establishments. What is wanted is larger numbers of moderate-sized trees of such kinds as are found to do best in each locality, with a reduction in most places in the number of varieties grown, and a better selection of sorts early and late, so as to prolong the fruit season as far as possible. In the majority of places we find a glut during part of the season, and an insufficiency during the rest of the year, a state of things anything but satisfactory.

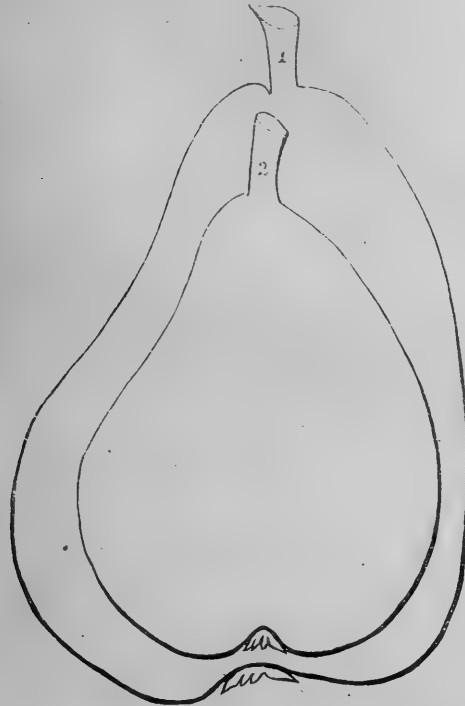

T. BAINES,
Southgate.

Figs in Mid-Winter.—Commencing with a number of fruiting plants in pots, as soon as the leaves are off, cut the shoots hard back to the old wood, leaving none of the young fruit on to form a first crop—protect the roots from frost, and leave the plants outside till the end of July, by which time they will have made a few inches of growth, and will again show fruit. They must now be taken into a warm, moist house, and if treated liberally will give a succession of fruit from October to February of much better quality than can be obtained from forced plants in spring. I have practised this plan three years with the same plants, and it has exceeded my most sanguine hopes. The sorts which I have proved to be well adapted for this mode of culture are Brown Turkey and White Marseilles.—WM. TAYLOR, Longleat.

NOTES ON NEW PEARS

I HAVE read M. Balte's account (p. 123) of Clapp's Favourite Poire de l'Assomption, Fondante Thirriot, and Beurré Balte Père. My Somersetshire experience with these four pears may, therefore, not be without interest.

The second has been grown by me during these last four years, and has fruited once. All my young trees of it are this season covered with blossom buds. As an addition to very early pears, nothing has appeared to equal it for many years. Besides earliness, too, it is most prolific, and the tree is robust, hardy, and easily distinguished from any other sort, by its strong upright habit. On the quince it forms beautiful trees, which show fruit the second year from the graft. In this it resembles the Pitmaston Duchesse d'Angoulême, which fruits the second year on the quince; and, in fact, some of the fruits of both sorts resemble one another very much; as does that fine pear the Brockworth Park, which also does well upon the quince.

No. 1. Beurre de l'Assomption. No. 2. Clapp's Favourite

As M. Baltet has so well described the Benrre de l'Assomption, I shall not venture to farther add to his remarks, but will pass on to Clapp's Favourite. I have cultivated this for about six or seven years, and have found it excellent; it is highly deserving of a place in every garden where early fruit is a desideratum. On open pyramids the fruit is middle-sized; but upon a wall it would doubtless come as large as M. Baltet mentions. It must, however, be large indeed if it at all approaches the size of Souvenir de Leopold I., which here attains three times the size of Clapp's Favourite.

As regards Beurré Balaït Père : although I have trees of it, they are yet too young to bear. I, however, saw specimens of the fruit at the Royal Horticultural Society's show on the 4th of October, and liked its appearance very much. If it turns out to be as good in quality as it looks, it will be a desirable variety.

Fondante Thirriot seems to be a promising tree; but with me it is

yet too young to yield fruit. I have these two last worked upon the quince, and will soon be able to prove them.

Whilst upon this subject permit me to add a dozen of delicious but little known winter pears to M. Baltet's list, and which are well worth a trial, even in small collections; viz., Angelique Leclerc, a fine Christmas pear, delicate and savoury; ripe here December 23rd. Augustine Lolleur, ripe March 26th, rich and excellent. Belle et Bonne de la Pierre, ripe December 15th; very rich, melting and savoury, with a nice sweet scent. Belle du Figuier, ripe January 16th; a fine new pear of honeyed sweetness and fine aroma. Belle Moulineo, ripe March 6th; this variety is quite new, and is a delicious, rich, melting and juicy fruit, with a nice scent when cut. Bourre de Bolwiller, ripe here April 18th; juice most abundant; savoury and delicate, deserves a wall. Bourr' Defays, ripe here February 24th; has a fine, delicate vinous flavour, and abundant juice. Bourr' Delamoy, November 20th; an exquisite, rich and melting pear. Bourr' Fideline, ripe Christmas, 1870; melting, rich, and deliciously perfumed. Choisnard, ripe here March 4th; flesh breaking with a rich, musky juice, and delicate flavour, deserves a wall. Comte de Flanders, ripe this Christmas, and kept till the 15th instant; very juicy, rich and perfumed with an exquisite flavour. Doyenn' Flon Aine, ripe here February 16th; flesh melting, juice most abundant, and deliciously perfumed.

Even to our old and well tried varieties, the above will, I am sure, be found to be welcome additions. J. SCOTT.

PEARS AND THEIR SELECTION

THE possession of a large number of pears of undoubted excellence need not necessarily preclude the desire to secure other varieties approaching to the fullest extent the good qualities that characterise a fair proportion of the two thousand sorts now named and cultivated. I still venture to think we have yet much to do in fashioning our pears as florists' have done their flowers, into finer form, more enduring properties, and habits of growth that tend to annual fruitfulness, and greater beauty in the fruit. Our early pears are especially prone to pass away like fragile and fragrant flowers, that exhale their sweetness and perish. We want more enduring types amongst early pears than Doyenné d'Été and Citron des Carmes. We want a Marie Louise that will keep its treasured sweetness for us a few weeks longer than the exquisite, but transient, pear we still value so much. We want a Beurré Clairgeau, to keep until January, and to possess, with its great beauty, the qualities of sweetness, juiciness, and flavour that we possess in Winter Nelis. We want a Josephine de Malines less coy in rendering its sweet gifts; for, after tasting its glorious fruit, we begrudge waiting two years for a second feast. We want more English pears, like British Queen, Monarch, and the fine pears of Huyske. We want more pears of the character of the old Crassane, that may be kept ripe and fit for use for six weeks; and seeing that so much remains to be effected, and that so much may be done in perfecting the pear, let me urge all who have the means of raising a few seedling pears to do so, and in time we may achieve the results I have faintly shadowed forth as still desirable. The selection of a good parent, and the determination of the character of the union that is to be consummated, will render success more probable.

The accompanying list may be useful to some of your amateur readers who are about to plant pears. Our subsoil is clay; average rainfall, twenty-four inches; altitude, 237 feet above the sea level; locality, North Leicestershire:—

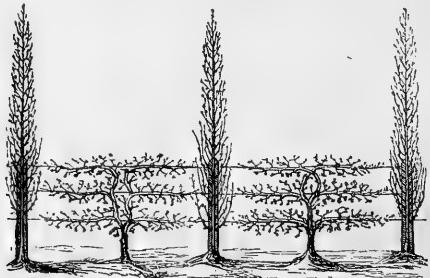

Citron des Carmes	Very early.	Poiré Pêche	Jargonelle
Doyenné d'Été	Grown generally on south-east and west walls.		
Beurré d'Amanlis	Autumn and Early Winter.	Beurré Superfin	
Louise Bonne of Jersey,	Van Mons Leon le Clerc,	Beurré d'Anjou	
better on standards than	large handsome, unequal	Prince Consort (Huyghe's)	
on walls	in quality	Prince of Wales	
Williams' Bon Chrétien	Beurré Clairgeant, very	Victoria	
Marié Louise	handsome; its beauty	Van de Weyer	
British Queen	is its dower	Orpheliné d'Enguichien	
Doyenné Bussoch	Suffolk Thorn	Doyenné du Comice	
	Crassane		
	Winter.		
Josephine de Malines	Winter Népis	Knight's Monarch	
Glout Morceau	Easter Beurré	Bergamotte de Esperen	
	Beurré Rance.		

W. INGRAM.

RAILWAY-SIDE FRUIT CULTURE.

Those who have travelled by day from Brussels to Louvain, from Gretz to Colomiers on the Chemin de Fer de l'Est, or from Leopoldsdorf to Soleman, on the Belgrad, Gratz, and Vienna line, cannot fail to have remarked that the railway is flanked at intervals on both sides by apple and pear trees, either growing naturally or trained as espaliers.

According to Dr. Morren's report in the *Belgique Horticole* of February 1869, the trees planted three years previously between the first-named towns had so far thriven exceedingly well, their branches already reaching up so as to form a third and fourth stage, and in the spring of 1868 the majority of them blossomed. They are placed seven feet apart, and trained on a fence of posts, thin horizontal iron bars, and cross rails, the posts being five feet in height by three inches or four inches in diameter, and the wooden rails one inch broad by two-fifths of an inch in thickness. The fence costs about threepence the running foot, and the wear and tear is estimated at one penny. When iron wire is used—and old telegraph wires come in most useful for the purpose—it may be attached every ten feet to a four feet high oaken post, the lowest wire being one foot and a half, the second two feet and three quarters, and the third nearly four feet above the ground. By means of an iron tightener or raidisseur, consisting of a screw and nut, the wires can be drawn tighter in spring and allowed greater play in winter; the chances of their snapping will thus be greatly diminished. One tree may be planted close to a post, and one midway between post and post—the trees will in that case be five feet apart; and if the plan of alternating an horizontal espalier with the columnar pyramidal form be adopted, the fence will in a few years assume the appearance indicated by the accompanying sketch, for which, as well as for much of what follows, the writer is indebted to Dr. Lucas, of Reutlingen.

Fruit Trees along a Belgian Railway.

If preferred, smaller intermediate posts may be used as supports for the espalier trees, and the wires extending from them to the large posts, to facilitate training of the branches, be made to slope upwards. As regards the method of training and managing an horizontal espalier fence, the following details may be of service:—A strong, well-rooted pear or apple tree, one year from the graft, is planted without being cut, at the place intended for it in the row, and about the middle of the ensuing May, when the sap is in full movement, will require to be bent down and fastened in a horizontal position to the lowest wire. To encourage the putting forth of fruitful side shoots along its whole length, incisions are made before all the dormant eyes, whilst too vigorous buds are pinched in. A good even growth of fruit wood will shortly be the result. Owing to the accumulation of sap at the point where the young tree is tied down, the shoot there thrown out will be stronger than any of the others; it must be allowed to grow freely, and be attached in an almost upright direction. In the following year it will require to be bent down and fastened in the opposite direction to the stem from which it sprung, and it then forms the second arm of the tree. To form the second stage of branches, which is the next operation, a shoot must be taken from arm No. 2, and, after being carried up as far as the second wire, be bent down and fixed horizontally. From this third branch, by repeating the operations of the stage below, a fourth leading branch is formed, and the second stage is then complete. As regards the upper or third stage, it may either be formed in the same or in a slightly different manner from the first and second, and in the sixth year the extremities of the two lowest branches will require to be drawn up, and either grafted by approach or otherwise attached to the two uppermost. If the tree push forth very vigorously at first,

its two leading shoots may be allowed to grow in an upright direction in the same year, and afterwards be attached horizontally to the wire.

Respecting the cultivation of columnar-pyramidal trees—a form to be preferred where, on account of the corn crops, much shade is undesirable—a good plan is to put in strong, healthy plants two years from the graft, and the first operation will consist in pruning away all side branches above the union of scions and stock. Incisions are afterwards made above the eyes, with a view to cause them to break out strongly, and in the following spring, the lateral shoots thus developed must be cut short back. During the second year, the

Section of Railway Embankment and Terraces for Fruit Trees.

same mode of proceeding as regards incisions and cutting back of sideshoots (to about one inch in length) should be continued, and the point of the main stem will require to be somewhat shortened. Later on, as the tree shoots upwards—and it will, if permitted, attain a height of fifteen, twenty, and even twenty-five feet—the topmost lateral branches must be pinched, whilst the lower ones are regularly cut back and not allowed to extend beyond one foot from the main stem. If incisions have been made in the latter as above directed, and successive prunings properly attended to, the tree will be clothed from summit to base with short fruiting branches, and in five to seven years from the time of planting will begin to yield.

When it is proposed to utilise the slopes and embankments of railways for fruit-growing, the system of planting the trees, whether espalier or free-growing, on terraces some two or three feet in width, will be found in many cases a very advantageous one; and not only apples and pears, but cherries, plums, gooseberries, currants, strawberries, filberts, walnuts, and other kinds of fruit and wood suitable to the locality, may also be successfully cultivated.

"Already in France and Belgium," wrote, in the spring of 1870, the correspondent of a contemporary (considering M. Baltet's report), "some companies have handed over their lines to a company which undertakes to clothe them with fruit trees. The results obtained are calculated to confound the incredulous, and there is reason to expect that, with the support of the Society of Agriculturists of France, all further hesitation on the subject will quickly disappear. Messrs. Place and Tricotel have published some elaborate calculations on the subject. They estimate that the extent of line brought into operation in France will soon attain a total of 15,000 or 16,000 miles, and that the maintenance and renewal of all this amount of permanent way, coupled with the plantation and maintenance of fruit trees by the sides of the lines, would involve an aggregate outlay during the next fifty years of £40,000,000. On the other hand, the produce of the fruit trees would, they calculate, be worth £90,000,000, being a net profit of £50,000,000, in addition to the maintenance of the way being secured during the long period of fifty years. Even making allowance for bad years and unforeseen losses, we still arrive at an undoubted profit." On some of the State railways of Sweden the plan is found to work well of engaging a competent man to superintend the cultivation of a certain number of station orchards and gardens, and perhaps it might answer to make some similar arrangement in connection with the planting, pruning, training, &c., of fruit trees grown on the sides of the line. Railway employees in those localities where the traffic is small, would thus be enabled to make a profitable use of their spare time, and, under the direction of an efficient staff of pomologists, be the means of turning to good account thousands of acres of what is now waste, unproductive land.—S., in "Field."

Fruit in Oregon.—Apples grow so big in Oregon that sixteen of them are said to have measured a bushel.

Peach Culture in America.—William C. Curry, says the *Chester County (Pa.) Record*, of West Bradford, set out on his farm an orchard of eleven hundred peach trees last fall.

THE KITCHEN GARDEN.

MINIATURE MUSHROOM BEDS.

No grapes, peaches, or plums fill the eye or satisfy the palate like those men grow themselves. On the other hand, everybody eats, but none but professional gardeners grow, mushrooms. The idea has got abroad that they are difficult to cultivate. This is, however, quite a mistake. They are capricious at times, but that only whets the appetite the more for their possession. Hitherto it has been thought by many that elaborate preparations were needed in the way of buildings, heating, &c., for mushroom culture, but I have mostly found that where the preparations were the most elaborate, there were the fewest mushrooms. In any place—back shed, floor of hothouse, cellar, stable, garret—where a temperature of 50° or 56° can be maintained, mushrooms may be grown. But it is not of such modes of culture that I would now write. We have heard of a Belgian cook who grew them in his old shoes, and assuredly they can be grown very well in four or six inch pots, pans, boxes, or even in a cracked tea-pot. The accompanying is an illustration of how they can be grown in the tops and bottoms of old casks. A barrel is sawn cross-ways into two pieces, each forming a tub. Holes are made in the bottoms of each, and a thin layer of good soil is spread over them inside. They are then filled with good, well-prepared stable-manure, just like that used in ordinary mushroom-beds, the different layers of dung in each tub being well pressed down. When the tub is half filled, six or seven good pieces of spawn are placed on the surface, and the remainder is filled up with manure, which is well pressed down, the operation being

Mushroom Tub.

completed by giving to the heap the form of a dome. The tubs thus prepared are placed in a perfectly dark part of a cellar, and eight or ten days afterwards the dung is taken off until the spawn is visible, in order to see whether it has commenced to vegetate and develop little filaments. If the spawn has spread, the surface must be covered with soil, care being taken to use only that which is fresh and properly prepared. In this or any similar way, there should be no difficulty in growing mushrooms; the boxes or tubs could be filled anywhere, and then carried into spare cellars, &c. In this manner objections against steaming manure might in many cases be got over.

There is one immense advantage in growing mushrooms in portable and small pots, boxes, tubs, or cask bottoms. When the manure gets cooled down, and the crop gets checked for lack of warmth, these portable contrivances, with their freight of young mushrooms, may be plunged bodily into warmer media, such as a sweet bed of fermenting dung. Crops can likewise be safely hastened or retarded by ranges of temperature from 65° to 45°. Thus they may be brought forth from the cellars and placed in forcing-houses at work or plant stoves, in cases of emergency. Even the cook might grow his own mushrooms in pots on his kitchen shelves or under his table, and when they come in with too great a rush, remove them to the cold meat larder to take a quiet nap till wanted. By plunging the pots or pans in a genial medium I have found that the fermenting material inside the pots may be almost dispensed with. The spawn runs best in a little sweet horse dung, that is, manure that has had its grossness sweated out of it by ten days' or a fortnight's gentle fermentation and four or six turnings upside down and inside out. Place a handful of this in a pot or pan, with one or more pieces of

spawn, according to the size of the pot; fill with soil, and plunge in a bottom heat of, say 55° or 60°, and in five or six weeks a crop of mushrooms will be gathered. Should the heat fail, renew it with fresh dung and re-plunge. By this method, a uniform temperature may be provided for the mushrooms through the whole period of growth.

Finally, I never could discover any difference between mushrooms grown in the dark and those grown in the light, and therefore the latter is by no means essential. Indeed, dry, warm cellars are among the best situations for mushrooms. Good spawn is the one thing essential, and whether it is purchased by the bushel or the single brick only, buy it of nurseries whose characters will guarantee its freshness and growing properties.

D. T. Fisi.

HOW TO FIGHT THE WEEDS.

It is a comforting fact that a garden may be kept thoroughly clean at much less expense than is required to maintain it in a weedy condition. A very little labour judiciously applied does more towards perfect cleanliness than a great deal brought to bear at the wrong time. Where weeds are allowed to grow large, they require ten times the amount of trouble to exterminate them than when attacked in a tiny seedling state. Some people never take notice of weeds till they begin to rival the plants in size, and perhaps illustrate the arrangements of nature for the dispersion of seeds by floating their feathery parachutes through the air. To allow them to seed is, of course, gross mismanagement; but to prevent them is not enough. They should never be allowed to get so large, that when they are cut off, it is necessary to remove them from the spot in which they grew. It is the raking and removing after the hoeing which causes the waste of labour. Once let them get up, and then it is not a mere hoeing that is required, but a "clearing" on a small scale. When cut down, it becomes necessary to remove the untidy swath from the ground, and to take it; and in doing this in a large garden we have seen as much labour thrown away as would be sufficient to keep one of twice the size in a creditable state. If ground is systematically and frequently hoed, no raking is required, and the young plants perish, and leave no trace after the first hour's sun they are exposed to. The Dutch hoe should be passed over the garden once a fortnight. An ordinary workman will cover a great deal of ground in one day, provided the weeds are not strong enough to impede his hoe. It should be done in fine or dry weather, to prevent the rooting of the weeds. Never mind if the ground "looks clean," a fortnight after it has received a thorough hoeing. Start the hoe again the second Monday morning; and by pursuing that system through the growing season the garden will always look clean. A good workman may hoe the garden over, and cut off all the weeds in the bud during a single summer's day; whereas, when they are fully or even half developed, a fortnight may be required to remove them; and through the season some part of the place is pretty sure to be "up to the eyes in weeds."

While many admit all this as regards annual weeds, they apply a different doctrine to bindweed, dandelion, docks, and the like, and take a roundabout way of exterminating them. But no weed can live if you persist in destroying its leafy or above-ground portion before it has had time to become well developed. This is indisputable. The obvious inference is that all weeds whatever may be destroyed in this way. By making it a rule to have infested plots or crops visited once a week or fortnight, and the weeds carefully cut off, you will get rid of every particle of noxious vegetation. Who has not seen the endless huntings and diggings after the roots of convolvulus? No amount of winter digging can exterminate this pest; but a very trifling but regular attention in summer will do so. We once knew an "experienced practical horticulturalist" who made a brave but expensive attempt to get rid of it. A plot of strawberries was infested by it, and very unproductive in consequence of its tortuous wrappings. Being a man of resolution, he determined to cart out the whole plot on to the farm, and he did it to the depth of two feet and a half! That cost a good deal of labour; but horses and men were plentiful, and soon carted in a lot of loam to fill up

the vacancy. *Convolvulus sepium* was exterminated from the plot for a time; but its removal required as much exertion as would suffice to clear a dozen acres. What was the best and cheapest remedy? Why, simply to "dig in" or throw out the strawberries, and plant a crop of, say, Brussels sprouts, or any thinly-planted crop, among which a boy could easily pass once in ten days during the growing season, and cut off at the ground the rising bindweed, which would probably attempt to twine itself round the stems, and thereby be the more readily cut off at the bottom. By persisting in that as long as a leaf showed itself it is not difficult to divine what would become of the roots, pertinacious as they are when allowed breathing space. In hoeing the garden, seed beds, and other such closely planted surfaces must of course be passed by; but they should be hand-picked nearly as frequently as the general surface is tickled with the hoe. Where box edgings are employed, they should, as a matter of course, be regularly hand-picked.

NOTES AND QUESTIONS ON THE KITCHEN-GARDEN.

The Tomato in Southern California.—The *Ventura Signal* says that the tomato in Southern California is a perennial plant, which blooms and bears fruit during the entire year, when properly cared for. Near the seashore, where there are no frosts, the editor has seen them of five years' growth, looking as fresh and vigorous as at any time of their existence. He adds:—"There are many classes of the vegetable kind perennial here that are elsewhere annual."

Guano.—The anchors of ships moored in the vicinity of the Chincha Islands frequently bring up guano from the bottom of the ocean, which is rather contrary to the doctrine that these marvellous deposits are the excreta of birds. The recent researches of Dr. Habel go far to corroborate Professor Edward's view that guano is really a stratified deposit. When the portions of guano which are insoluble in acids are examined, they are found to consist entirely of skeletons of diatomace, polycystine, and sponges, all of which are invariably of marine origin, and sometimes identical with those still living in the adjacent ocean. These forms are also found in patches exactly as they occur in nature. From these and other facts recently obtained by chemical and microscopical investigation, there appears to be but little doubt that guano is an accumulation of the bodies of animals and plants; which, either by heat, by chemical action, or both combined, has had its organic matter converted into bitumen, while the mineral constituents have been preserved in those beautiful forms which make up the infusorial strata in various part of the world.—*Mechanics' Magazine*.

Early Tomatoes.—There is no doubt that cuttings taken from the plants in the autumn, just before freezing up time, stuck in damp soil, and when well rooted removed to six-inch pots, kept in an atmosphere of 40° to 50°, and watered just sufficiently to keep them alive during winter, and by keeping the shoots as they appear properly pinched, and a part of the larger leaves, so as to retain growth as much as possible, is the true way of obtaining the earliest fruit. It will be found that if the plants are well attended to, by the spring they will be thick and strong at the base, and as woody almost as a wallflower. Growing tomatoes, as almost all gardeners do, in hotheds is decidedly the wrong method, as no doubt many of them have found out. The hothed plants are weak and spindling. Many put down seeds in this way so early that the plants run up to the glass before the weather becomes sufficiently warm to put them out in the open ground; and the leaves either scorch or become frost-bitten. I have seen many a frame of tomatoes for which I would not give five cents for the best five hundred plants in them.—*Conrad Farmer*.

Mushroom Culture.—Last summer I spawned my small cucumber frame and my narrow bed, but, although the spawn worked freely, I did not gather one dozen mushrooms, a few tiny ones, rather larger than peas, being the only result. In August last I had two champagne cases filled with good horse-manure, and when they were spawned and covered with ordinary garden mould, they were placed in a shed in the garden, open in front, but not much exposed. When the weather became cold they were covered with litter and mats; but, alas! at present no mushrooms. Can you suggest anything that would be likely to bring them on? I ought to say that my gardener ascertained that the spawn worked freely, and is still alive, for the manure has a strong odour of mushrooms. Last year I tried to cultivate mushrooms on the asparagus beds, during the winter—spawned the manure when they were covered for the autumn, and then carefully covered them with litter. The winter was unusually cold, but we never had one mushroom, and I fear we shall be equally unfortunate with those in the shed this year. If you can offer any suggestions I shall feel obliged.—*A Lover of Mushrooms.*—[You deserve success, though you clearly made a mistake in spawning the asparagus beds in winter. Mushrooms are grown in abundance in the open air in winter, as may be seen in the market gardens at the west end of London and in those round Paris, but they are always grown on well-prepared beds, thickly covered. As to your other mishaps, no one can help you who does not know all the circumstances of the case. In your cucumber frames, &c., they ought to have succeeded, but as they are plants notoriously

variable as to their appearance or non-appearance in a wild state, we must expect them to be equally capricious in gardens, except when grown in structures in which we can almost exactly regulate the temperature and conditions. Persevere, and, if possible, have several beds always at work in the same structure. Where mushroom culture is tried on a very small scale, failure is very apt to result from the neglect of some trifling attention, or from mere forgetfulness.]

Preserving Cabbages.—Many Americans grow cabbages by the hundred acres; it is not, however, of their culture I am about to speak. Out of the system of preserving them when full grown during winter, together with some of the uses to which Americans put them during that season. Here everything except the very hardest of the kales is usually wholly destroyed before Christmas. North-west winds and sharp frosts dry up all moisture, and a sudden change of temperature afterwards finishes what escapes the ravages of the ice king. The thermometer on the Wednesday and Thursday nights preceding Christmas, indicated 6° and 7° below zero, accompanied by quite a gale of wind. On Friday we had about five inches of snow; rain then fell, and the thermometer gradually rose to 32°; then on Saturday evening it ran up to 56°; the increase of temperature clearing all the snow off in about three hours, and this state of things with slight variations will be continued throughout the winter. The way in which we keep cabbages good until May under such circumstances is to choose a piece of dug ground where water will not stand, and as soon as the ground is about to freeze up, to fork up the full-grown cabbages, and place them roots upwards in a row close together, banking up the earth round them like a celery ridge, and leaving the roots exposed. A portion of the ground is covered over with leaves, hay, or other covering, to keep it from freezing so hard as to prevent getting the cabbages out while frost lasts. Some use leaves only as a covering; and no doubt they keep the cabbages safe, but they are apt to give them a bad taste. In England I have seen waste cabbages come out of a rubbish heap quite fresh in spring; therefore this plan of preserving them during very severe winters might perhaps be worth attentive consideration.—JAMES TAPLIN, South Amboy, New Jersey, United States.

Value of some of our Vegetable Imports.—The official returns of the imports of foreign and colonial merchandise into the United Kingdom in 1871 show, in regard to many articles, a material difference in computed real value from that of the preceding year. Taking the great article of raw cotton, our largest import, we find the quantity imported in 1871 15,843,890 cwt., being an increase of above 82 per cent. over the quantity in the preceding year, but the computed value of the total import, viz., £55,767,545—shows an increase of not much more than 4 per cent., over that of the preceding year. The computed value of a hundred-weight averaged nearly £4. 10s. in 1870, and a little more than £3. 10s. in 1871. The import of flax (dressed and undressed) and tow advanced from 2,373,528 cwt. in 1870 to 2,597,915 cwt. in 1871; but the value of the import declined from £5,979,127 to £5,791,188. Indigo imported increased from 79,254 cwt. to 135,901 cwt., but the value only from £2,721,203 to £2,932,233. The items of food also show various differences from those of the preceding year. In 1870 we imported 35,705,138 cwt. of wheat and wheat-meal and flour, of the value of £19,447,778; in 1871 we imported 43,392,284 cwt., but the value rose at a greater rate than the quantity, and amounted to £26,783,912. In 1870, 77,154 cwt. of potatoes imported were priced at £245,252; in 1871 the 85,125 cwt. import, at only £225,732. The import of tea shows an increase in quantity from 141,020,767 cwt. in 1870 to 170,716,140 cwt.; but in price only from £10,097,619 to £11,657,684. On the other hand, while the quantity of currants imported increased from 513,763 cwt. to 1,068,887 cwt., the value rose from £492,023 to no less than £1,483,841. The import of wine presents remarkable figures; the quantity shows the slight increase from 17,774,782 gallons in 1870 to 17,870,078 gallons in 1871; but the value of the import shows a rise from £1,317,294 to £7,060,557. The import in 1871 of red wine from France cost us £1,064,690, and of white wine, £1,272,972; white wine from Spain, £2,367,630, and wine from Portugal, £1,303,638.

The Jute Trade.—The *Dundee Advertiser* says that a noteworthy fact in connection with the staple trade of Dundee during the past year is the immense increase that has taken place in the quantity of jute imported to the town. In no former year has the importation direct from India attained to anything like the magnitude which it has reached during the year just closed. Statistics, carefully compiled, show the number of bales that have been landed at Dundee from Calcutta direct during the past year to be 468,692, which, compared with the quantity imported in the previous year—213,875 bales—shows an increase of 254,817, being 40,942 bales more than double the quantity imported in 1870. On the other hand, however, the coasting trade—i.e., by vessels reloading at London and elsewhere for Dundee—has fallen off to a considerable extent. Last year the importations coastwise amounted to 210,038 bales, as against 317,691 for the previous year, showing a deficiency of 107,653 bales. The traffic in jute by rail to Dundee shows an advance in favour of last year of about 1,982 bales. As regards the total importations to the town, the figures exhibit largely to the advantage of the past over the previous year, there being 739,498 bales for 1871, as against 590,352 for 1870, or an increase of 149,146 bales.

NEW PLANTS OF 1871.

COMMENCING with the hardier series, we propose here to pass in review some of the more important acquisitions of the year which has just passed away. The number of the new plants which annually come to the front is really astonishing, and we can do no more than briefly indicate those which in our opinion are the most desirable amongst them.

In the group of hardy evergreen trees and shrubs we find *Quercus striata*, a Japanese tree, half-hardy, or possibly hardy in sheltered places. This is pyramidal in habit, and its ovate lanceolate, toothed leaves are distinctly banded with oblique lines of green and gold. The French gardens have *Wellingtonia gigantea pendula*, a drooping-branched variety, said to be well-marked and ornamental. The *Juniperus chinensis aurea* is probably one of the finest of recent evergreens, being hardy and free-growing as the type, and well-marked with a thoroughly fixed golden variegation. Amongst deciduous trees *Maackia amurensis* is the most decided novelty. It comes from the valley of the Amoor, bears pinnate leaves, and produces long, dense, spike-like racemes of white papilionaceous flowers. The ever-blooming *Robinia Pseud-Acacia semperflorens* of French gardens, which is said to continue flowering from April till autumn, must be a fine ornamental tree. *Albizia rosea*, a North American tree, hardy in Paris, is very floriferous, and its heads of long crimson stamens are very showy. Then we have two more of the pretty Japanese Maples in *Acer palmatum ornatum* and *A. palmatum crispum*. Passing on to deciduous shrubs, we find *Cerasus Sieboldii roseo-plena*, a beautiful shrub with pendent branches and double rose-coloured flowers; and *Cerasus pendula rosea*, slender and drooping, the branches profusely laden with blossoms of a delicate pink, both Japanese; *Rhus Osbeckii*, also Japanese, with handsome pinnate leaves having winged rachises; two Mock Oranges—*Philadelphus rubricanus* and *P. parviflorus*, both Chinese, and said to be of ornamental character; *Rhododendron (Azalea) molle*, a fine Japanese shrub, with bold deep orange-yellow flowers, and likely to be the parent of a numerous progeny of garden varieties like the hardy *Azaleas* of America; *Rosa rugosa*, at first called *R. Regeliana*, a dwarf and very distinct Japanese species, with large crimson flowers like single Peonies; and *Lonicera Periclymenum aurum*, with golden variegated leaves.

The hardy perennial group has yielded the following subjects of merit:—*Primula japonica*, with its tall, whorled spikes of rich magenta blossoms; *Linum campanulatum*, a very much improved *L. flavum*, from the south of Europe; *Lithospermum petreum* and *L. Gastoni*, also eupatorium, two dwarf plants, with charming blue flowers; *Androsace carnea eximia*, in which the umbellate flowers are rosy-purple; *Baptisia leucophaea*, with trifoliate leaves, and long reclinate racemes of white papilionaceous flowers; *Saxifraga Mawiana*, a Morocca plant, with large white flowers, and prolific bulblets; *Saxifraga valdensis*, a little alpine gem, of minute growth, with large white blossoms; and *Thymus citriodorus nardo-marginalis*, a beautiful yellow-edged dwarf Thyme, suitable for bedding-out.

Annuals are few in number. The most remarkable is *Amaranthus salicifolius*, a half-hardy species, adapted both for in-door and out-door decoration, of pyramidal habit, with pendent, narrow, charmingly multicoloured leaves, and certainly one of the best plants of the year. To this may be added the hardy *Collinsia violacea*, with white and violet flowers, and compact habit; and *Gilia liniflora*, like a white-flowered flax.

New ferns are not numerous. *Dicksonia Sellowiana*, a noble Brazilian tree fern, has been introduced to the Belgian gardens. *Humata*, and *Davallia Tymermanni*, a charming evergreen stove fern, from West Africa, and has a freely-creeping silvery-scaled rhizome, and small, deltoid, tripinnate fronds. *Elaphoglossum Herminieri*, the Eel-fern, though having only simple fronds, forms a good new stove fern for baskets. *Plecoptilis irioides cristata* is a well-crested form of a well-known species. *Trichomanes auriculatum* is one of the lovely creeping-stemmed Javanese Film-ferns, with long, narrow, transparent fronds. *Lycopodium dichotomum*, *L. madiocianum*, and *L. taxifolium*, are three interesting species of club-moss; while *Selaginella rubella* is a creeping-stemmed species of the same order, with reddish-tinted leaves.

Succulents have been chiefly confined to Agaves, of which very ornamental genus, many new, or at least unfamiliar species, have been brought forward. The best of these were *Agave Celsiana albida*, *deibada compacta*, *imbricata*, *ixthioides*, *Simsii*, *elegantissima*, *Mescal*, and some of its varieties, *Regelii macrodonta*, *rotundifolia*, and *Verschaffeltii variegata*.

Amongst bulbs are some new Lilies, a family now happily engaging the attention of cultivators. *Lilium Washingtonianum* is one of the finest of them, growing 3 feet to 5 feet high, with many large purple-tinted, white, sweet-scented flowers. The Eastern Asiatic *L. Maximowiczii tigrinum* has lovely orange-red flowers, spotted with purple; and *L. Roczlui*, from the Rocky Mountains, is an ally of the beautiful *superbum*. In *Gastroneura sanguineum flammum* we have a lovely dwarf greenhouse bulb, with large funnel-shaped rosy-crimson flowers. *Nerina pudica*, of *Halbanthus*-like aspect, also a greenhouse plant, has white flowers streaked with red. *Gladifolus Saundersii* is a very handsome South African species allied to *G. psittacinus*, but with the decurved flowers scarlet and white. Finally, *Xiphion filiforme* and *X. junceum* are two bulbous Irises of showy character, the first with rich, violet-purple, the last with golden-yellow flowers. Two white-flowered *Bouvardias*, *B. Davisoni* and *B. Vredelandii*, both apparently sports from the variety called *Hogarthi*, are choice acquisitions in this useful decorative genus, which requires warm greenhouse treatment. *Encephalartos Vroomii*, in the way of *E. villosus*, is a fine greenhouse cycad. *Tacsonia speciosa*, with carnation-coloured flowers, is a remarkably handsome greenhouse climber. These are the more important acquisitions in the greenhouse section.

New stove plants are, as usual, very abundant, and we can only glance at a few of them. In the flowering section we find the following specially worthy of note:—*Dipladenia insignis*, the finest of all the Dipladenias with very high-coloured rosy-carmine flowers. *Glossyra jasminiflora*, a Brazilian evergreen shrub, with corymbose panicles of long-tubed freely-produced white flowers. *Ixora Colci*, a splendid exhibition plant, with immense heads of pure white flowers. *Ixora amabilis*, remarkably free, deep orange-coloured variety. *Begonia Chelsoni*, a hybrid from *Boliviensis*, with bright orange-tinted red-flowers. *Bomarea chontalensis*, a grand stove climber from Nicaragua, with waxy rose-coloured and yellow flowers blotched with brown, one of the last contributions of the lamented Semann. *Aristolochia cordifolia*, another stove climber, from Mexico, with creamy purple-blotted flowers, having an immense cordiform limb. *Aechmea Mariae Regiae*, *Vriesia corallina*, and *Bromelia Fernandina*, three grand Bromeliaceæ, the first with great rosy-pink bracts, and blue flowers, the second with green flowers on the axis of distichous purplish-red bracts, the third with a great globe head of numerous recurved cinnabar-red bracts, subtending greenish-white flowers.

Stove foliage-plants again are very numerous, the best being:—*Paulinia thalictroides*, a woody sapindaceous climber, with triterately pinnate leaves, like fronds of some elegant Adiantum. *Sphaerogyne imperialis*, a noble Melastomad from Peru. *Nepenthes Sedoides*, a pretty hybrid pitcher plant. *Maranta Mazellii*, a handsome species, with broad rotundato leaves, marked by two grey bands. Several Dracanas, as *D. amabilis*, with green leaves and pink and white variegations, far superior to *Guiffoylei*; *D. Wisemannii* with bronzy, red-margined leaves breaking out into white; *D. splendens*, a dwarf, dense-growing form, with short, broad, recurved bronzy leaves breaking into rosy carnine; and *D. magnifica*, a very handsome sort, with erect broad bronzy leaves, margined with red, and having a pinkish bloom. Several Arads, as *Dieffenbachia imperialis*, bold-leaved, dark green, with grey rib and distinct yellow spots; *D. Bausei* and *D. Bowmanni*, both of stocky habit, yellowish green blotched with dark green, the former also spotted with white; *Alcasia Marshallii*, like *Jenningsii*, but with a central silvery band added; and *Xanthosoma Lindenii*, with erect sagittate-hastate, deep green leaves, the ribs and veins of which are ivory-white.

Amongst exotic Orchids, we can only mention these:—*Phainis Marshalliae*, a charming terrestrial species, with large white flowers having a lemon-tinted lip. *Sobralia macrantha albida*, a variety with creamy-white flowers and rosy lip. *Oncidium aurosum*, with a crowded erect panicle of golden-yellow flowers, spotted with rich brown. *Epidendrum Frederici-Guilelmi*, a tall species, with short broad racemes of deep crimson flowers. The curious *Epidendrum Pseudepidendrum*, with bright green flowers, having a bright vermilion-orange lip. *Masdevallia Lindenii*, *M. Harryana*, and *M. ignea*, three beautiful dwarf cool-house species, the first with the flowers brilliant violet-rose, the second rich magenta, and the third bright cinnabar. Finally we may record *Cypripedium Ashburtonia*, a handsome hybrid form of Lady's Slipper, exactly intermediate between its parents, *C. barbatum* and *C. insigne*.—*Florist and Pomologist*.

Condurango Root.—This reputed specific for cancer is becoming a subject of speculation in Ecuador and the United States. In Ecuador it has reached £17 a ton, but in New York it has been selling for fabulous prices, though its virtues are contested. The Government of Ecuador has imposed an export duty.

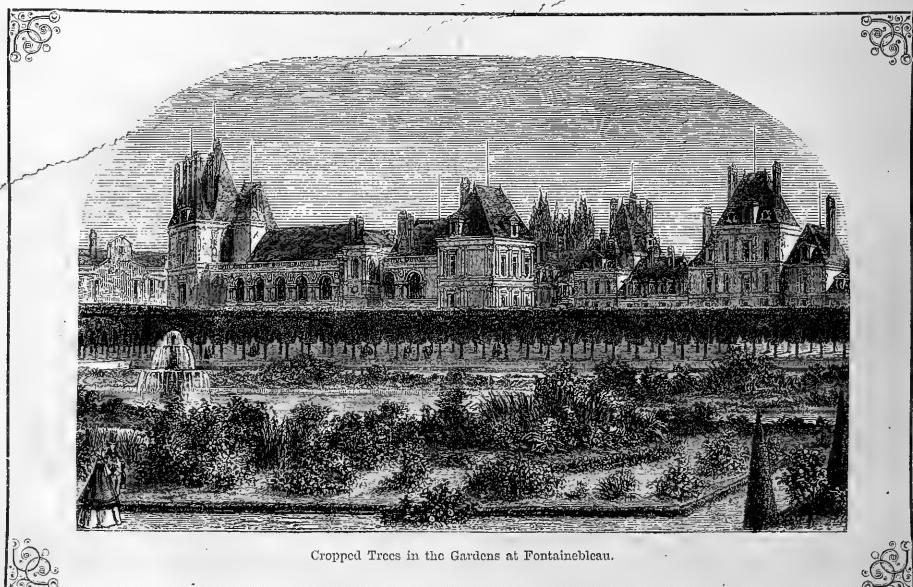

GARDEN DESIGN.

CROPPED TREES AND ARCHITECTURAL LINES.

BY NOEL HUMPHREYS.

WHEN it is considered how exquisitely the natural forms of trees contrast with the rigid lines of architectural structures, it becomes difficult to conceive how the "artist in foliage" could, by any process of aesthetic reasoning, ever have brought himself to forego the picturesque advantages of the forms he was called upon to deal with, and wilfully enter into a disadvantageous rivalry with the rule and plumb-line of the architect. That the irregular symmetry of tree form, with its softly rounded outlines, produces the most agreeable impression on the eye when placed in direct contrast with the regular lines of architecture, both horizontal and vertical, admits of no dispute; and yet, in some of the most remarkable instances

His contemporary, Le Notre, an artist of still greater and more general artistic accomplishment, fell into the same errors as regards the distortion of the natural forms of trees, with the mistaken idea, as it would seem, of making them accord with those of architecture, instead of making use of them as a natural and delightful contrast. The embellishments which he created in the splendid gardens attached to the Chateau of Vouc-le-Viscompte for the celebrated Fouquet resulted in such a striking success, as it was then deemed, that contemporary writers did not hesitate to call it "a scene of enchantment". The Great King pronounced it a *spectacle merveilleux*, and appointed the triumphant artist controller-general of royal buildings and designer of gardens, with the privilege of incurring outlays of fabulous amount. While in the employ of the king he also constructed the ornamental (?) canals and designed the avenues of cropped lines which disfigure the noble architecture of the grand old Chateau of Fontainebleau, and entirely conceal some of its finest lines in the lower storeys.

Cropped Trees in the Gardens at Fontainebleau.

in Europe in which the combined effects of architecture and foliage have been sought, and that, too, upon a magnificent scale, the destruction, and not the adoption, of the charming contrasts that naturally exist between trees and architecture seems to have been the one thing specially sought after. Le Pautre, who in the middle of the seventeenth century was one of the most eminent of the great garden decorators of France, and without whose grottoes, fountains, terraces, and other embellishments, no palace or chateau was then considered *au grand complet*, persisted in creating "walls of foliage" as well as walls of stone, and so flung away one of the greatest elements of beauty in the various important works confided to his skill; for the well-squared forms of his cropped trees injured the effect of his architectural lines, and the more perfect accuracy of the last glaringly exposed the futile attempt to rival them in shaven foliage. He was, nevertheless, a man of genius and of infinite artistic resource; his works in architecture, and also in sculpture and painting, having secured his election to the Académie de Peinture et de Sculpture in 1677.

The above illustration serves to show how that ill-conceived line of straightened tree-tops (in which careful shearing still preserves the unfortunate device of Le Notre) cuts the architectural composition in two, and utterly conceals its lower half. From this example of the effect produced by a continuous line of trees running parallel with an architectural facade, may be seen the fatal effect (minus the cropping) which will eventually be produced by the uninterrupted line of trees planted along the Thames Embankment, which will at no very distant period conceal both from the river and the roadway the greater portion of the stately facade of Somerset House, and the other noble buildings destined to rise along other portions of that noble site.

The following illustration is intended to exhibit the effect of a mode of treatment in which the naturally irregular, but yet symmetrical, forms of trees are made to form a striking and most agreeable contrast with the rigid lines of architecture, rather than distorting and clipping them, in order to produce a false and ineffective attempt at an impossible concord. The example is by no means one of the best that might have been

selected, either architecturally or arboreally considered, but it possesses the great advantage of being well known. It is a view of Buckingham Palace, as obtained from the Suspension Bridge in St. James's Park. Neither the planting nor the architecture are of the highest kind, and our artist has not even made the most of them, such as they are, being only asked for a rough sketch, by way of diagram. In that sense, the sketch serves its purpose sufficiently well, and shows plainly enough the pleasing contrast which the natural forms of trees present to the well-marked lines of architecture, both vertical and horizontal. The view itself, slightly shadowed forth in our hasty sketch, is indeed a very pleasing one, the relative proportions of architecture, foliage, and water, being, as a whole, judiciously preserved. Enough is seen of the building, as the chief object, to display its importance and general character to advantage, the termination of its main façade being shrouded in uncertainty by a veil of foliage, and its lines boldly intercepted at one point by the dense mass of trees on the island, from which interruption the resumption of their accurate course on either side produces a very satisfactory and pleasing effect. An increase of height in the building itself, and a greater amount of rich and varied detail, would, perhaps, have rendered this example more conclusive as against "formalism in foliage;" but, as an illustration of the abstract principles advocated, it is an all-sufficient example.

GARDEN DESTROYERS

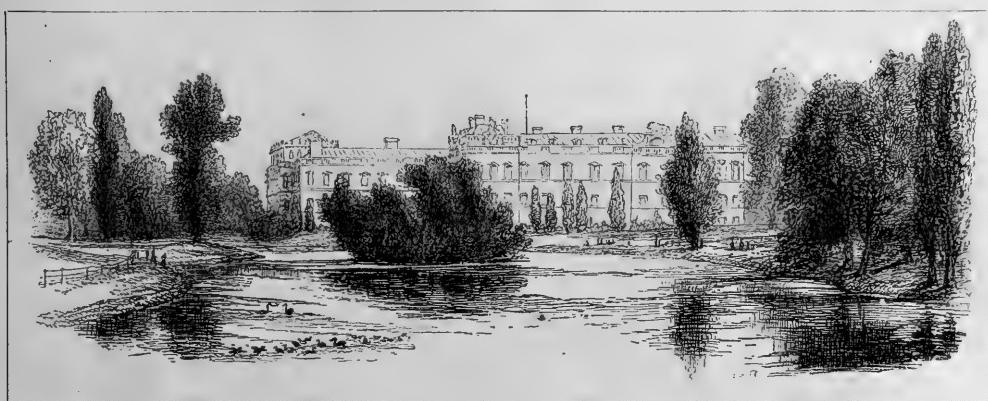

APHIDES: THEIR FRIENDS AND THEIR FOES.

BY EDWARD NEWMAN.

THAT aphides live on the sap of plants is susceptible of ocular demonstration, and equally so is the fact that ladybirds and aphidions live on aphides. The plant louse, or aphis, is familiar to every gardener, although the particular species may not be known to him. They are so numerous, and so closely packed together, that they seem to form a garment, a top-coat, to many of our common plants, for instance the rose and the broad bean.

Plants afflicted by aphis exhibit the most extraordinary vagaries, bearing blossoms where they ought to bear leaves, leaves where they ought to bear blossom—twisting into corkscrew-forms stems that ought to be straight, and making straight as sticks those which ought to be bent; sometimes, as in the peach and nectarine, they make the leaves hump up in the middle, and produce a sort of make-believe nectarine; making roots blossom, as we often see in that ornamental shrub, *Pyrus japonica*. This is a phenomenon that is sure to attract

Buckingham Palace, from the Suspension Bridge in St. James's Park.

The Gardens at Warwick Castle.—The unfortunate fire at Warwick Castle has been the means of bringing to light many interesting associations connected with this fine old monument of times gone by. We have had the remarks of Nathaniel Hawthorne and Emerson's impressions of English scenes and scenery reproduced under different phases, and, lastly, a very interesting scrap from one of the lively epistles of Horace Walpole, the very emperor of English letter-writers, has found its way into the papers. It is a nice little bit of criticism concerning gardens and landscape gardeners, for which we are glad to find room. It appears that Walpole visited Warwick in the summer of 1751, and writing of his visit, to his friend George Montague, he says:—"On my return from (Umbertide) Lord Archer's, an odious place,^{*} I saw Warwick, a pretty old town in the form of a cross, small and thinly inhabited. The castle is enchanting; the view pleased me more than I can express. The river Avon tumbles down a cascade at its foot. It is well laid out by one Brown, who has set up on a few ideas of Kent and Mr. Southcote. One sees what the prevalence of taste does. Little Brooke, who would have chuckled to have been born in an age of clipped hedges and cockleshell avenues, has submitted to let his garden and park be natural. Where he has attempted Gothicisms in the castle he has failed, and has indulged himself with an apartment which is paltry. The chapel is very pretty and snugged up with tiny pews." Walpole, however, though he often preaches so witty about "naturalness" in park and garden scenery, did not always practise it—for in his gardens at Strawberry Hill were worked up nearly all the vagaries of the worst formalism of his time.—H. N. H.

the attention of the most unobservant; the roots of the *Pyrus* are very near the surface, and of course liable to be uncovered by every operation of the gardener. So sure as this uncovering takes place, a colony of aphides take up their abode on the exposed part, and soon compel the roots to make this strange exhibition.

One or two other effects of the attacks of aphides are also very peculiar. *Aphis bursaria*, by the influence of its sap-sucking propensity, causes the leaf-stalk of the Lombardy poplar to expand into a bladder-like swelling, which constitutes a home for its progeny. These bladders or purses I find very commonly on the poplars on Nun Green and Peckham Rye, and I am still in doubt how the species is preserved; for, the purse falling with the leaf, one would suppose its inhabitants would perish. It is probable that a few of the winged females escape, and lay their eggs on the twigs of poplar, to remain there during the winter, and in the spring the young ones probably find their way to the newly-formed leaf-stalks, puncture them, and thus originate the purses, which are such conspicuous objects when the summer is advanced. A second species—I think it is *Bursocrypta Ulmi*—produces on the common elms strange hollow cysts, which so exactly resemble figs in size and shape that they may easily deceive the superficial examiner. Of these figs I have had a good supply from young elms near Cambridge; on being opened they were found to contain a good deal of saccharine fluid and a great many carwigs, in addition to numbers of aphides and larva of Syrphi. A third species produces a most beautiful green gall on the spruce fir, very closely resembling the cones of that tree, but much smaller. The insect which produces these galls was called *Chermes Abietis* by

Linnæus, but Ratzebourg, the author of a beautiful work on Forest Insects, thinks there are two species engaged in this manufacture of artificial fir cones, in one of which the cone is formed in the middle of a twig, and the other at the very tip. A fourth species invariably fixes its residence on the roots of the creeping plume thistle (*Carduus arvensis*), and, so far as I am aware, never ventures above ground, but resides continuously on the subterranean stolons of this troublesome weed. In this situation it lives in perpetual darkness, in company with the ants, which appear to take special interest in its welfare. This connection of ants and aphides has long been known to naturalists, and has given rise to very diverse opinions as to the nature and object of the connection; but it has been clearly shown by competent observers that the sap of a plant extracted by means of the rostrum or sucker of the aphis passes through its system, and is discharged through two minute tubes, one situated on each side of the aphid near the extremity of the body. "When no ants attend them," say Kirby and Spence, "by a certain jerk of the body, which takes place at regular intervals, they ejaculate this honey to a distance; but when ants are at hand, watching the moment when the aphides emit their fluid, they seize and suck it down immediately. This, however, is the least of their talents, for they absolutely possess the art of making them yield the honey at pleasure, or, in other words, of milking them. On this occasion their antennæ are their fingers; with these they pat the abdomen of the aphid on each side alternately, moving them very briskly: a little drop of fluid immediately appears which the ant takes into its mouth, one species (*Myrmica rubra*) conducting it with its antennæ, which are somewhat swollen at the tips. When it has thus milked one it proceeds to another, and so on, until being satisfied it returns to its nest." The illustrious Linnæus, a century earlier, was equally acquainted with this astonishing fact, for he says, "The ant ascends the tree that it may milk the aphides, not kill them."

This connection between ants and aphides comes nearer to our idea of personal property among mankind than any other phenomenon exhibited in the animal kingdom. All aphides seem to be the property of certain ants, or rather colonies of ants—not of individual ants, but certain companies or establishments of ants; they possess a prescriptive right, as the late Sir Robert Peel would have called it, to the aphides settled on a branch, or a tree, or a rose bush; and, when once this right or interest in these miniature cattle, so to speak, is obtained, by what process I know not, it is maintained with the utmost jealousy, and no ants from a neighbouring colony are allowed to interfere or infringe on the manorial rights of those in possession. It will, however, occasionally happen that there is a stronger colony of ants in the neighbourhood than those actually in possession; then the same process takes place as in Christian nations—the stronger and more numerous invade the weaker, and possess themselves of the twigs or trees laden with these illipituit cattle, and a curious process is to be observed. After the possession of the disputed territory has been obtained by the invaders, the conquered may be seen carrying off their cattle, each ant with an aphid in its mouth, to some place of fancied security; the unresisting aphid submits to this process with the most perfect nonchalance, takes it as a matter of course, and forcibly reminds one of a puppy or a kitten being conveyed by its parent to a place of greater safety. Sometimes when the ants think that their treasures, these herds of kine, are in too close proximity to stronger colonies or settlements of ants, they resort to a really wonderful expedient for their protection; they bring grains of earth from a distance, and construct a casing or sheath of earth-works, a kind of tubular casemate or rampart, round a twig or branch on which a peculiarly valuable and productive herd of aphides are grazing. I have never seen the nobler ants invade these casemates; probably this is a kind of property which they hold sacred.

We may conclude that ants are the best if not the only friends of the aphides; they never forsake them; they are equally attentive and unremitting in their attention day and night; I have often visited my colonies with candle and lantern, and always found the aphides constant to their task of sap-sucking, and the ants equally constant in theirs of milking them.—*Field.*

Bean aphid (*Aphis Fabæ*).—The following remedy for this pest is said to be practised with success on the Continent:—As soon as the young heads are seen to be affected, they are cut off, and of course destroyed, and the effect of the amputation is to harden the plant, so that the aphid cannot pierce the skin.

English Sparrows in New York Squares.—For some unaccountable reason, the little English sparrows which have filled the parks and trees for several years have disappeared this season by thousands. It is suggested that, inasmuch as they were regarded as city property, they entertained fears of being stolen by the "Ring," and so flew off to some honest region.

THE PROPAGATOR.

THE ART OF GRAFTING.

(Continued from page 201.)

KEEPING THE TOOLS.—They should always be in a serviceable and clean condition. In the course of repeated operations, especially when the sap is flowing freely, it thickens and accumulates on the blade. It should be constantly removed by the application of water or moist earth. The dirt interferes with the proper management of the tool, and injures the internal layers of the bark and wood which come into contact with the blade. Frequent sharpening of the cutting implements should not be neglected, as wounds heal much more readily when the cuts are clean. When the tool gets blunt, it should be ground down on a grindstone, and afterwards rubbed on a finer stone to remove the wire-edge. In long-continued operations the tool should be rubbed on the fine stone frequently during the day. The Turkey, or any other fine-grained stone, is the best for sharpening pruning-knives. The slate-stone is suitable for the grafting-knife and the sécateur. There is also the fine stone used for razors and penknives; on this, with a drop or two of oil, fine blades for delicate operations are sharpened. In nurseries, after passing the tools over the stone, they are stropped on the leather of the boot or shoe, or on the palm of the hand. The mode of sharpening depends on the skill or the practice of the operator. The object should be to sharpen the cutting parts without weakening them; otherwise, in rough work, the edge will soon become blunt, and is easily notched. The saw is sharpened with a file made for the purpose. Delicate tools, and even the sécateur, should be sent to the cutter.

LIGATURES.—Almost all the modes of grafting require a ligature to fasten up separated tissues or raised bark, to tie clefts together, and to keep the graft firmly on the stock. If any considerable interval should be allowed to occur between the insertion of the scion and the application of the ligature, the action of the atmosphere would not fail to have an injurious effect on the graft. The best ligatures are those which can neither expand nor contract under hygrometric influences, and which possess a certain amount of elasticity permitting them to accommodate themselves to the increasing diameter of the stock without cramping it. The thicker the stock is, the firmer should the ligature be; for in this case the healing of the wound is naturally more tedious, and everything should be done to accelerate it. In cases of grafting where the bark only has been raised, it is sufficient to bring the cortical layers together, and to tie up the graft without compressing it. The ligature is applied with both hands. It is rolled in a spiral manner around the grafted part, drawing it tight at every turn, especially at the beginning and the end, where it is most liable to become loose. It does not matter whether the turns are made very close to each other or not, the essential point is that the ligature should keep the graft firm. Should it yield on passing the finger over it, it is not sufficiently tight, and must be done over again. Woollen thread combines all the qualities to be wished for in a good ligature; it adapts itself to the growth of the tree, and is not affected by moisture, as it has been passed through oil in its manufacture. It is very much used in bud-grafting on small branches and medium-sized fruit-trees and shrubs, conifers, and rose-trees, or small stocks grafted in the open air or under glass. Two or three threads of it are put together, (without twisting them) in lengths proportioned to the thickness of the stocks, and the depth of the clefts to be covered. For large stocks, this thread would not be sufficiently strong. Cotton-thread is not affected by hygrometric changes, but it does not possess the elasticity of the woollen material. We recommend it for bud-grafting on strong stems, or such as are of slow increase in bulk, and also for grafts under glass. In applying it as a ligature it is best to fasten it with a knot so that it can be easily untied; when it

becomes too tight, as cotton is difficult to cut across, and the same ligature can then be used another season. The expense of purchasing cotton and woollen materials for ligatures in nurseries has led to an inquiry for cheaper substitutes. After trying various species of carex and bulrushes, two aquatic plants were found which supply an excellent material for ligatures. These are the Reed Mace (*Typha latifolia*) and the Bur Reed (*Sparagnum ramosum*), both of which grow in abundance on the banks of rivers and ditches, in ponds and marshes and belong to the natural family of Typhaceæ. The plants are gathered when full-grown, either about the end of summer for the following season's use, or in spring to be used the same year. The leaves, which are thickly crowded at the base, are separated, and put to dry in the shade or in a loft, where they are hung up in bundles formed by tying the ends together. When the time for using them arrives they are cut into the lengths required, usually from one foot to twenty inches. A short time before grafting, these ligatures tied in a bundle are plunged into water, where they are left for a few hours; they are then taken out and wrung dry in the same way that linen is wrung. Very often they are merely put into a collar to keep them cool and moist, and in places where water cannot be conveniently employed, they are placed under the soil with the same object. This kind of ligature requires a proper medium of dryness and moisture. If too dry, the leaf of the Reed Mace or of the Bur Reed will not have sufficient resisting power, and will break; if too moist, it will cause the graft to

advantages, and the ligatures which they furnish will not injure the tender bark of the young wood in various kinds of grafts. Pack-thread, single or doubled, or old twine unravelled, are very often used because they are easily procured. They should, however, not be twisted, and must be carefully looked after when the graft begins to swell. Split osiers are hardly ever used except in country places, where anything better is not always to be had. They may be employed as ligatures for old trees, whose diameter does not increase so rapidly as to cause injury in any form to result from over-tight compression. The bark of the elm and the willow, dried and afterwards moistened, are neither better nor worse than the split osiers. Their defect is that they contract too speedily, unless they have been prepared a year before-hand. The office of the ligature is a temporary one; it ceases when the union of the parts is sufficiently advanced for the development of the graft. We shall see further on, when we come to discuss the subject more at length, what additional attention is required by the ligature, and at what time it is considered to be proper to disengage with it.

GRAFTING-WAX.—In grafting it is necessary to cover the wounds and cuts with an unctuous composition, which will not have the defect of drying-up or burning the wound, nor of running or cracking under the action of the air or from being badly made. This must be applied copiously and without stint to the wounds and clefts of both stock and scion when the graft is fixed in position. A well-executed graft may fail in consequence of the bad quality of the wax. Those modes of grafting in which no cut surface is exposed to the air, bud-grafting for instance, do not require any application of this kind. In spite of numerous new inventions, good compositions are still few, but those which we possess are sufficient.

GRAFTING-CLAY, OR UNGUENT DE SAINT-FIACRE OF THE FRENCH. This primitive composition consists of two parts of clay and one part of cow-dung. It is held on the graft by means of pack-thread or a piece of rag, and presents the form of an oblong ball. Some persons put a strip of bark between the cut and the composition, to prevent the latter from penetrating into the clefts. Others mix finely-chopped hay or grass with it, to give it more consistency. Two thousand years ago, authors recommended the covering of the "knecaded luting and glue of the graft" either with a borage leaf or with moss. Grafting clay is much used in many country places, and is an economical composition, especially for the grafting of all sorts of old trees.

WARM MASTIC.—For a long time, nurserymen have manufactured their own mastic. The composition of it varies; the base being usually Burgundy pitch, black pitch, bees-wax, suet, and resin. To these ingredients some add ochre, hog's lard, flowers of sulphur, Venice turpentine, or sifted cinders. All are melted together over the fire in an iron pot, and the composition should be allowed to cool before it is used. Practice makes it easy to judge of the proper proportions of the ingredients; the pitch tends to thicken the composition, the suet to make it lighter, the resin imparts dryness to it, and the bees-wax gives it oiliness. The following mixture is in high repute at the establishments of MM. André Leroy, of Angers, and Baltet Frères, of Troyes:—First, melt together, resin 2 lbs. 12 ounces, Burgundy pitch 1 lb. 11 ounces; at the same time melt separately, suet 9 ounces. Pour the suet, when thoroughly melted, into the first mixture, stirring it well while doing so. Then add 18 ounces of red ochre, dropping it in gradually in small portions, and stirring the whole up for a good while. Whatever composition may be used, it should always be unctuous, easily worked, and free from acidity, and is best applied lukewarm, rather cool than hot, and when of a consistency approaching the liquid rather than the solid. It is brought into this condition with the help of a small portable stove, heated like a warm bath, or with a spirit-lamp, or by any of the common methods. It is applied with a small paint-brush, or a stick with a rag wrapped round the end, or, better still, with a wooden spatula. The warm mastic is an economical kind for large operations, and is preferable to the cold mastic for autumn grafting, as the frost has been found to have less effect upon it.—Charles Baltet, Troyes, France.

Reed Mace.

Bur Reed.

rot, in addition to being just as brittle as in the other case. The leaf is generally broad enough to be divided lengthways, and fastens better when it is put on edgeways, and not laid flat, and when it is slightly twisted in winding it round the graft. With the exception of those modes of grafting which require the woody tissues of the stock to be cleft, and for which the leaf of the Reed Mace or the Bur Reed is not sufficiently tough, we recommend this ligature for the greater number of grafting processes. The soft leaves of the common flag (*Iris pseudacorus*), which do not cut like the leaves of the carex, will furnish a pliant and firm ligature, but not so strong as the preceding. The bark of the lime-tree, as it is prepared for the manufacture of well-ropes, furnishes a good ligature for cleft-grafting or crown-grafting, or grafting by approach, and in all cases where it is necessary to oppose a certain amount of resistance to large stocks or broken tissues. Dipped in water, then dried and divided, this kind of ligature possesses a suitable amount of elasticity, and does not tighten on the stock, as pack-thread or hamper-twine would. Packing-mats, which come as coverings of colonial imports, offer the same

THE PROVIDENT WOODPECKER.

(MELANERPES FORMICIVORUS.—BONAP.)

The accompanying woodcut represents a feature which may occasionally be seen in the bark of the Yellow Pine (*Pinus ponderosa*) in California. It is pitted with holes, and if the observer takes the trouble to inquire what has caused them, he will learn that they are the work of a bird—a woodpecker, which makes the holes and stores up acorns in them for future food. The following particulars regarding this bird are taken from a communication made to the Royal Physical Society in 1854 by Mr. Andrew Murray, who was the first to direct attention to this peculiar habit, he having received specimens of the perforated bark and an account of the proceedings of these birds from his brother in California, who had seen them bore the holes, store the acorns, and hammer them in so tightly that you can hardly pick them out. He had also seen the birds take them out again in spring, and then eat either them or something that was within the shell. He had seen six or eight of them at work on a tree, in which there was a squirrel which had made its house in a hollow at the root of a branch. This squirrel seemed to take great interest in these storing operations. He would pop out his head, and the moment the coast was clear he would run out and scratch away at the bark to get at the acorns deposited. As soon as the birds saw him, they would all attack him, and he would run like lightning down one side of the tree and up the other, and into his hole again; then peep out and watch another chance to do the same.

When these facts were first communicated, nothing more was known of the bird than that it was a black woodpecker with a red head and yellow throat, and Sir W. Jardine provisionally proposed for it the very appropriate name of *Picus providus*. Unfortunately, when specimens came (which they did soon afterwards), it was found that the species was known, having already been described by Prince Bonaparte under the name of *Melanerpes formicivorus*, in ignorance of its most remarkable distinguishing character.

Subsequently, Mr. C. J. Jackson, in the *Proceedings of the Boston Natural History Society* (vol. x., p. 227), states that it selects in the autumn, for stowing away, acorns only which are infested with maggots to serve as food for its young next spring, and that the acorns are driven into the holes prepared for them, so as to prevent the escape of the maggot when it comes to maturity and imprison it until wanted in the following spring. Mr. J. K. Lord, on the other hand ("The Naturalist in Vancouver's Island" (vol. i., p. 289), doubts its provident habits.

The method in which it stows its store of acorns is illustrated by Mr. Sumichrast by a figure in the *Memoirs of the Boston Natural History Society* (vol. i., p. 562), and the *Ibis*, in 1868 (p. 106), gives an account of the matter; but the whole seems to stand very much where it was put by Mr. Murray in 1854. Although it may be that the woodpecker makes the store for future food either as acorn or enclosed grub (for there are plenty of woodpeckers that are vegetable feeders as well as insect feeders), its doing so cannot be regarded as providence on its own behalf, either for itself or its offspring; for it is impossible that it can recognize which acorns it stowed away and which its neighbour stowed. However this may be, acorns keep better so stowed than they usually do if they are still sound, either for the woodpecker's eating or the grub's eating next spring after laying up. We should imagine, however, that they would be in fine condition for new grubs, especially if the shell is broken a little in hammering them in, which seems to us a more reasonable supposition than Mr. Jackson's, that only acorns already stricken are selected. A sight of the grubs, if there be grubs, would soon settle that point; but until some qualified entomologist has reported on them, we must be content with the information which we now possess in the matter.

C.

THE
GREAT GARDENS
OF EUROPE.

VERSAILLES.

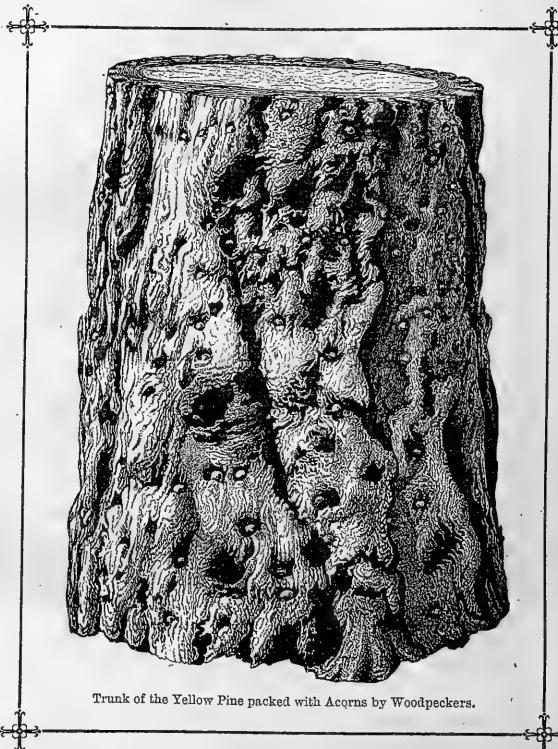

BY NOEL HUMPHREYS.

The gardens and park of Versailles are so celebrated and, from a certain stand-point of art, so magnificent, that a critical observer at once sets himself to inquire how it was that such a vast outlay of money, and so huge an amount of labour, should have been lavished upon a site so entirely unpropitious. The explanation is simple enough, for the fact is, the spot

was not a specially selected one. It was partly from accident, and partly from the influence of conflicting circumstances, that the nearly flat, and in every way uninteresting, country about Versailles became the site of by far the most splendid of European palaces. The land was so poor, that the scanty crops formerly raised upon it were scarcely worth harvesting; and they were so exposed to cold and violent currents of wind blowing up the two great damp valleys in summer, that the grain was often *versé*, that is, laid, even before it attained its full growth; and so the crops, if gathered at all, were gathered as laid crops, or *versailles*—from which, it is said, the place took its uninviting name.

The only attractions it held out to royalty were the woods with which it was surrounded, parts of which were fragments of very ancient forests. It is on record that some of the

Trunk of the Yellow Pine packed with Acorns by Woodpeckers.

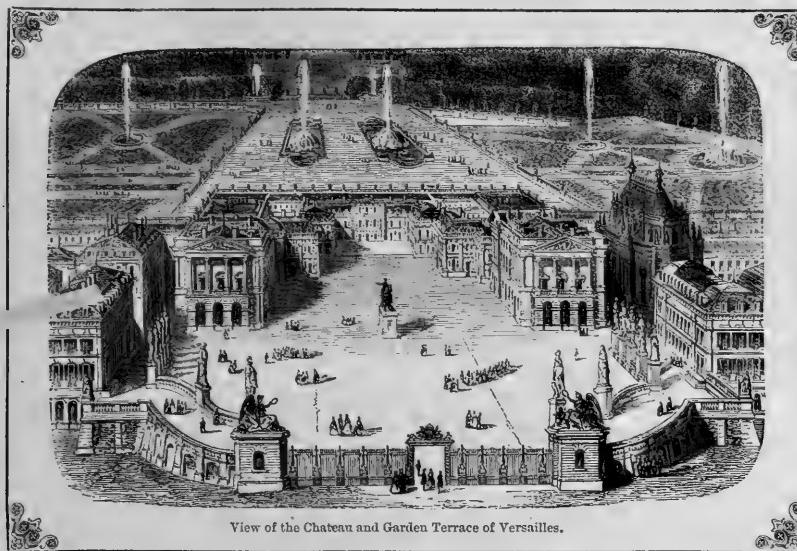

ancient Frankish kings had a manorial residence near the site of the present vast chateau, at a spot still known as Frouconville; but Louis XIII. was the first of the Bourbon kings who established a hunting seat in that neighbourhood, where he generally resided during the autumnal months. He purchased the site from the Archbishop of Paris (into whose hands the land had passed) in 1627, and the erection of the *rendezvous de chasse*, which still forms that portion of the grand palace that faces the Avenue de Paris, was commenced in that year.

The sites of most of the great chateaux of the French kings, like that at Versailles, were, indeed, selected on account of the immediate proximity of woods and forests which afforded good hunting ground, as St. Germain, Compiègne, Fontainebleau, Amboise, Chambord, and others; none of them, except St. Germain, having any other attractions of situation. St. Germain, possibly from the magnificence of its site, became the more favourite of the royal residences after the time of Francis I. Henry IV. took up his permanent residence there; and Louis XIII. was born within its walls, and a great pile

to become beautiful. The first sculptors of the day were employed, not only upon detached statues, groups, and the crowds of allegorical figures attached to fountains, but the chisels of men of great eminence were engaged even upon the marble vases to ornament the more salient points of the Perrons and balustraded parapets of the grand terraces. In 1682, the designs of the king and his architects being nearly complete, the Court was established at Versailles, and the renown of the great palace of the Great King spread far and wide all over the world, ranking as an eighth wonder.

Le Notre had been the presiding genius, not only of the gardens, but of the principal features of the palace itself, as director-in-chief of all the royal buildings. He laboured incessantly, and, with the full command of various arts, of which he possessed both an instinctive and cultivated knowledge in a very high degree, achieved a brilliant conquest over the seemingly impracticable nature of the site. In the estimation of his contemporaries, his triumph was complete.

He opened spacious and stately avenues through the extensive woods, and in these openings caused the gleaming waters

View of the Chateau and Garden Terrace of Versailles.

of new buildings was added to the more ancient part of the castle during his reign. Anne of Austria, with her young son, Louis XIV., disgusted with the troubles of the Fronde, quitted Paris to take up their residence there; and, as the story goes, eventually abandoned it in consequence of one of its greatest charms, namely, its noble terrace, which commands a far-stretching view over the whole of Paris, and enables the spectator to see even the distant spires of St. Denis pointing heavenward above the ancient sepulture of the kings of France. The vainglorious king, it was whispered, could not bear the daily view of an object which continually reminded him that he was not immortal; and, actuated by that feeling, caused great additions to be made to his father's *rendezvous de chasse* at Versailles, and in 1661 went to reside there, though the vast plans were not at that time half completed.

Further additions were continuously made during the next twenty years with a lavish outlay, which was thought all-sufficient to overcome even the stubbornness of the unsuggestive natural features that had to be dealt with, and force them

of vast canals to sparkle in the far perspective; and broad expanses of turf were made to extend as far as the eye could reach, even from the commanding position of the terrace, which was made some fifty feet higher than the general level of the gardens and park, being the only rising ground available, and previously known by the name of the Butte de Versailles.

The engraving above shows a bird's-eye view of the Cour Royale, which extends in front of the two detached buildings forming the chateau of Louis XIII., and which were eventually joined together by the vast body of the newer palace, the façade of which looks upon the gardens. Over the back of the parapet of that façade, the gardens are seen, with the fountains playing, the commencement of the long turf plot known as the Tapis Vert being visible beyond. This glimpse, however, can convey but a slight idea of the splendour of the fountains, with their crowds of marble or bronze statuary and costly decorations of every conceivable kind; and cannot for a moment suggest to the imagination the immense profusion of glistening water which is being tumbled wildly into the

marble-bound basins, or cast into the air to extraordinary heights from countless single jets. Nor is it possible, on so small a scale, to convey any just idea of the quaint devices of the more complicated fountain-work. Neither can any representation whatever, let it be as picturesque and artistic as it may, suggest and explain the marvels of engineering skill with which that vast water supply was procured from such an unfavourable country as the district which surrounds Versailles. The celebrated Labyrinth is but a minor feature in this enormous horticultural and picturesque composition (for picturesque it is, with all its formalism), but it is very remarkable for the amount of invention and labour displayed in its decoration; the results being at that time deemed so interesting that a special volume, entitled "Le Labyrinthe de Versailles," was published in French, English, and German, describing the endless variety of the inventions lavished upon it; many of which most certainly require that their absurdity should at all events be explained. At the entrance, for instance, is seen, on one side Cupid holding the guiding-thread of the maze; while on the other side is Esop, the fabulist, the moral of whose fables is intended to suggest the idea of wisdom; while Cupid is supposed to be declaring to those whom he has led into the Labyrinth of Love that he will, if they are wise (that is if they study Esop's fables), help them out of the scrape he has led them into. The fountains in this famous Labyrinth illustrate the fables in question. There are the singing birds attacking the owl for the harshness of his nightly screech, each and all squirting water upon him with fury. Next come "the monkey, the cat, and the chestnuts"; cat, monkey, and chestnuts squirting water fiercely at each other; and so on with a score of other illustrative devices of singular puerility; so low could the genius of the *Siecle de Louis XIV.* sink in the midst of all its grandeur.

The costly residence in the park known as the Greater Trianon, and built by the Great King for his celebrated mistress, was called Trianon from a village of that name which was swept away when that portion of the park was enclosed. This "Trianon" had but little to distinguish it in style from the vast neighbouring palace except its smaller scale. To the Lesser Trianon, built in the time of Louis XV., who wished occasionally for still greater retirement than the Greater Trianon afforded, a botanic garden was attached, on the suggestion of the Duc d'Ayen; an addition which would scarcely have called for a passing remark but that the admirable Jussieu became the curator, and there worked out the theories of his new system of botany, now so well known as "the natural system," which has nearly superseded the more artificial one of Linnaeus.

In the early and tranquil portion of the reign of Louis XVI. the Petit Trianon was assigned as a private residence to Marie Antoinette, and under her directions the grounds were converted (as we now see them) into a *jardin paysage*, which included in its features a rustic village, with its farm, its mill, its dairy, its streamlet, its rustic bridge, and even its old castle. Here it was that those triflers, the Comte de Provence and the Comte d'Artois, with the beautiful young queen and others, pleased themselves sometimes in performing the rustic occupations of shepherds, millers, or dairymaids. The *jardin paysage* proved a fascinating one; and rivals were soon created in many other places than the Petit Trianon. It was thought delightfully natural and picturesque; and those who admired it as a natural garden, with its winding stream and rustic bridge, natural cottages and imitation mill, did not guess that it was almost as unnatural as the formalism of the straight avenues and marble basins and sculptured fountains of the great palace garden itself.

The annexed plan will show the situations of the principal features of the gardens and woods of Versailles; of the crossing canals, called Le Petit Venise, with its village of gondoliers, spoken of by Rousseau; of the great basin, excavated by a regiment of Swiss Guards, and known as the Piéce des Suisses; and also of the orangery, the pheasantry, the menagerie, the aviary, the Fountains of the Dragon, of the Falls of Apollo, of Diana, of Latona, and a number of other points of interest.

(To be continued.)

PUBLIC GARDENS.

THE ROYAL GARDENS, KEW.

I HAVE been a frequent visitor to these gardens for more than forty years, and I must certainly say that, taking them as a whole, I have always admired them; it is, therefore, with reluctance that I put myself in the position of a fault-finder. But I should like to ask why the Deodar vista, between the Great Palm House and the Pagoda, has been blocked up—a vista in which, I know personally, the late Sir W. Hooker took much interest. In this the rows of Deodars stand about 150 feet apart, and about 50 feet asunder in the row; and to create interest and present effect, a row of scarlet thorns was planted inside the avenue on each side, which, as a temporary matter, was well enough. Now, however, within the Deodar lines, about 25 feet apart from them and about 45 feet asunder, in the row, are planted in *threes*, *four to five feet apart*, oaks, beech, birch, ash, elms, chestnuts, hornbeams, maples, hickory, willows, alders, elders. If allowed to grow, they will ultimately destroy the effect of the groups of Deodars; and if not allowed to grow, why plant them at all? Can any reason be given for planting trees in such a manner? If the reader who has not seen what I allude to will imagine three Lime trees placed like these dots ° ° °, with four feet between each tree, he will understand me. It is hardly necessary to say that the Deodar is second to none as a foreground tree, when its graceful and weeping habit is not interfered with. Again, Cedars of Lebanon are planted within twenty-five feet of the Pagoda! Look at those at Chiswick-House, and see what shifts Mr. Edmonds has to make to save the mansion, and then judge whether it is advisable to plant cedars within twenty-five feet of a temple such as is the Pagoda at Kew. Near here, also, may be seen hedges of common laurels surrounding fine clumps of rhododendrons, the branches of which are sweeping the grass. Deodars have been planted in the Sion vista alternately with limes. The Deodars are about 160 feet apart, by 100 feet in the row, which is an excellent distance, permitting their distinguishing characteristics to be seen to full advantage; for though it is not to be expected that they will reach 200 feet in height, still they may 100 feet. It is, therefore, high time the limes were removed; they have already done their duty, having been, of course, planted at the time only for present effect. But, in place of this, the authorities have planted a row of Abies Douglasii within the line of Deodars on each side, about twenty-five feet from the broad walk, and 150 feet apart in the row, introducing two evergreen oaks betwixt. Now, a clump of silver or Douglas firs, flanked with evergreen oaks, has a good effect in large places; but, in this case, if these trees are allowed to grow and assume their natural habits, they will assuredly close up this fine vista altogether. Had these Douglas firs been planted 100 feet back from where the limes are now, they would have formed fine background to the Deodars. Surely, it is wrong to plant Abies Douglasii in front of the Deodars, even had there been room, which there is not. But, strange to say, the planters in question are not even satisfied with blocking up this vista with oaks and firs—they have planted a part of the distance with *Cupressus Lawsoniana* within four to five feet of the broad walk, and about twenty feet asunder in the row. Where there is so much capability, and so much power, as there is at Kew, one cannot help feeling sorry to see any misdirection of them. As far as sweeping, cleaning, &c., are concerned, the place is well enough; but it is here one ought to have an example of tree planting and of landscape gardening worthy of the country.

Hounslow. D. FERGUSON.

[The influence of our public gardens is so great that it would be unwise to repress discussion on their merits and arrangements in this, a journal in which the subject of public gardens is regularly treated of for the first time in gardening literature. Therefore, reasonable and inoffensive expression of opinion, having for its manifest object the improvement of our public gardens, will be permitted in our pages. No communication, however, criticising the management, will be inserted without the writer's name in full. We are not responsible for the opinions of our correspondents.—CONDUCTOR.]

New Cemetery at Edinburgh.—Arrangements are in progress for providing a new cemetery for Edinburgh. We trust it may prove as well arranged and as beautiful as a garden as the Dean Cemetery, than which we know none more creditable.

THE IN-DOOR GARDEN.

PALMS FOR THE GARDEN.

(Continued from page 134.)

CALYPTROCALYX SPICATUS (*MOLUCCA*).—A noble palm, with the habit of an Areca, but denser. Not a fast grower. Where a large plant is required to stand over a tank this would be very useful. When it is eight feet high it spreads from ten to fourteen feet, the points of the fronds nearly reaching the ground.

CALYPTROGYNE SARAPIGENIS (*TROPICAL AMERICA*).—Fronds spreading; pinnae regular, from two to four inches wide; stem smooth, two inches thick; stoliferous.

A distinct palm, but not one of the most ornamental, being rather coarse and formal.

CATEBLASTUS PREMORSUS (*VENEZUELA*).—Fronds spreading; pinnae flat, three inches wide, abrupt. A tall-growing plant, with lax habit; foliage dark-green; stem three inches thick; not a good decorative plant.

CARYOTA CUMMINGII (*PHILIPPINES*).—The leaf stalks clothed with dark scales; they have the appearance of gigantic Adiantums, and contrast well with other palms or fine-foliated plants. They are very ornamental plants at all stages. Fronds spreading; underside of petiole round; pinnae increasing in width from base upwards, producing the appearance of having been bitten off at the end; grows from sixteen to twenty feet high, when it begins to flower from the top downwards. When the last flowers have faded, it dies, and one of the suckers takes its place. The whole of this genus are bipinnate.

C. MITIS (*COCHIN CHINA*).—A dwarf plant, with triangular pinnae; fronds somewhat lax.

C. FURFURACEA (*JAVA*).—Fronds pendent, ten to fourteen feet in fully-developed plant; pinnae triangular; top cut irregular; where they join the petiole they are swollen. Young plants good for vase decoration or as table plants. Young shoots produced from base.

C. CAUDATA.—A very elegant variety of furfuracea, having the half of the terminal pinnae of each set lengthened, which gives grace to the plant.

C. RUMPHIANA (*CELEBES*).—Fronds spreading, six feet long and four feet wide in developed plants; pinnae rhomboid, regular. A noble plant, differing from the others in density and compactness of growth.

C. SOROLIFERA (*MALACCA*).—Fronds erect; pinnae irregular. A smooth-looking plant of dwarf habit, producing shoots from base when quite young. A good table plant.

C. URENS (*THE WINE PALM OF INDIA*).—A tall-growing plant with clear stem; the best of all the species for a large house, and the gem of the Palm House at Kew. Fronds spreading; pinnae, wedge-shaped, pendent. The lower side deeply gaged, giving it an elegant and airy aspect. In a young state it is a good table plant. In general appearance Caryotas resemble one another very much, and where one is required for a dwarf plant, Cummingsii is the best, but where space is no object, urens should be selected.

CEROXYLON ANDICOLA (SYN., *NIVEUM*: *WAX PALM OF BRAZIL*).—Fronds, erect, fourteen to sixteen feet; pinnae, channelled on under side, white; upper side, bright green. An elegant palm tree for the central position in a conservatory; not good, however, even in a young state for house decoration. Might be mistaken for *Diplothemium* when not fully developed; but it is more erect, and not so dense.

CHAMEOREAS.—These are the most elegant of palms, for small houses, as indeed, for any situation. They may be grown under the shade of other plants, or used as canopies for ferns, so as to furnish diversity and contrast. Having so slight a stem, crowned with an elegant head of foliage, they make fine table plants, and, not being

fast growers, they remain suitable for such purposes for a considerable length of time. They enjoy a moist atmosphere, and as regards arrangement, their foliage should always stand clear of anything with which it may be associated, not only on account of effect, but because some of the species have a beautiful flower spathe, which, when developed, is scarlet and orange, and exceedingly beautiful, forming a fine contrast with the dark-green foliage.

C. LUNATA (*MEXICO*).—Fronds, irregularly pinnate, two feet long; pinnae, in sets of from two to three, eight inches long, three inches wide; acuminate, point bent downwards, caused by the undulation of the margin. A plant of good appearance.

C. MICROPHYLLA (*BRAZIL*).—Fronds, irregularly pinnate; pinnae, convex. A dwarf and not very elegant plant.

C. MARTIANA (*S. AMERICA*).—Fronds, regularly pinnate, four feet long; pinnae, acuminate, one inch wide. The most charming of the group; on account of the fronds overarching the pot, and also on account of the plant itself being dwarf, it is very useful as undergrowth, or for the decoration of vases, or as a specimen on a pedestal.

C. PYGMAEA (*MEXICO*).—A dwarf species, with pinnate fronds. Rather stiff in habit, and requires a large pot.

C. SARTORII (*MEXICO*).—Fronds, pinnate; pinnae, oblique, ten to twelve inches long, two inches wide, rather

dense; allied to *Ernesti-Augusti*, but not so stiff; fronds, slightly recurved, two feet long. A very good palm for mixing with ferns.

C. WENDLANDII (*MEXICO*).—Fronds, regularly pinnate. A fine plant, but very like *Lindeniana*, from which it differs in the pinnae being slightly broader.

C. AMAZONICA (*TROP. AMERICA*).—Fronds, four feet; one foot to first set of pinnae, short and oblique. A good plant for mixing with ferns.

C. ARENBERGIANA (*GUATEMALA*).—Fronds, regularly pinnate; pinnae, long, acuminate. A fine, bold looking species, and a free grower.

C. ERNESTI-AUGUSTI (*NEW GRANADA*).—Fronds, simple twenty-two inches long, bifid; veins prominent, petiole short; white line, on the under side; female flower-spike, coral red, and very handsome; plant, rather stiff in habit, but worth growing for the sake of contrast.

(To be continued.)

J. CROUCHER.

The Wine Palm of India. (*Caryota urens*.)

CONSERVATORIES IN THE NATURAL STYLE.

No one can be more alive than I am to the absence of taste in the generality of conservatories in this country, but I am sure that they are infinitely more satisfactory than they possibly could be made by M. André's arrangement, which, if carried out, would, in some two years or so, reduce them to a much worse plight than the Palm House at Kew, to which he alludes by way of illustration. Let anyone possessing a moderate knowledge of vegetable physiology, and fair cultural skill, go to see the Palm House at Kew, and after studying it fairly the conclusion he will inevitably come to, must be, that for the object for which Kew is intended—namely, the bringing together of as many members of the vegetable kingdom as possible, more with a view to their individual well-being than for general effect—more could not have been done. Kew must be looked upon as an educational establishment where all who take an interest in the vegetable kingdom can make an acquaintance with thousands of plants they would not otherwise have an opportunity of seeing. Consequently, the first consideration has been to make the collection as comprehensive as possible, whereas if the plants had been arranged for effect, space would have been sacrificed that could not possibly have been spared.

In a south-westerly direction from the Palm House is another house, of far less imposing appearance externally, containing a selection of plants, which for individual interest and general effect as a whole—in fact, seen from every point of view that it is possible to judge them from—leave little room for complaint.

M. André's scheme resolves itself into three propositions: the preparation of the ground, the selection of the plants, and the planting. Bottom heat is unnecessary for any plant he named, and worse than useless in such a situation, as it would entail no end of annoyance in upsetting the ground to get at leakages, which are certain to occur in the pipes. The temperature he proposes, 65° to 68°, is nearly twenty degrees too high; he must have a reduction of ten degrees in the night, necessitating a day temperature of nearly 80°, which would kill two-thirds of the plants the first winter. But it is the selection of the plants which renders the whole thing impracticable. Plants in all respects so different from one another as those he proposes to plant can never thrive in the same temperature. If M. André will reduce his mean temperature to 50°, and ascend the Chilian. Andes a few thousand feet, go to the temperate regions of China, and the warmer parts of Japan, he will find abundance of plants in every way suited for the situation he proposes. For the roof, care should be taken to select such climbers as will not, by their rampant growth, effectually smother everything under them, or necessitate their being made continually unsightly by cutting-in. The plants that are intended to occupy the body of the house should be such as will rather receive benefit from the shade of those overhead than otherwise. From the countries I have just named and others, a selection can be made which will not only satisfy the requirements of good gardening from a cultural point of view, but will also please the eye of good taste. T. BAINES, Southgate.

[In justice to M. André it may be necessary to remind the reader that he did not find fault with the arrangements at Kew, but simply mentioned the large house there incidentally with others of a similar class, as suitable for such dispositions as he proposed. Whether the natural system of arrangement would be desirable for a botanic, as distinguished from a private, collection, is a question entirely apart from the general one. Our own opinion is that it is not a mere question of taste between conservatories arranged in the ordinary way and in the natural manner; one is right and the other wrong. It matters little whether the natural manner be carried out after M. André's or Mr. Baines's fashion. The natural method is the true and satisfying one, and moreover, the one best suited to the gardener, inasmuch as it saves much time, and enables him to produce a ravishing effect in winter, and indeed at all seasons, with a comparatively small number of flowering plants. The common way of exhibiting red pots, stages, and comparatively small plants in conservatories, simply makes the infinite grace of vegetation impossible therein. And this in the very house which we place near the mansion to show the choicest treasures of our collections! Surely, it is no wonder that many persons refuse to have any kind of conservatory near the house, so long as there is a chance of its presenting the paltry aspect so commonly seen. Happily, however, the decided improvement made in many of our ferneries, is making numerous converts to the cause of true gardening among us. These will soon carry the same principle to our conservatories, and we shall, 'at no distant day,' see these as satisfactory from the point of view of arrangement, as they are at present for rich collections of admirably grown plants. It is, of course, quite possible to arrange a hot as well as a cool house on this principle; and, on the whole, the cool house would be most desirable for us.]

SOILS, MANURES, &c.

FOOD FOR THE GARDEN.

THIS is the season to get a stock of land food together. Hungry land—and most of it, whether garden or farm, is hungry—will eat almost anything. Cannibal-like, it would not refuse even a slice of other land, if nothing better came to hand, and sometimes a change or mixture of fresh earth is as stimulating as a coat of the best manure; in fact, it is manure, that is, it adds to the hungry ground what it lacked before, and it is by such additions that the strength or productive force of the earth is preserved intact. Our crops have, as it were, two strings to their bow. One points skyward, and draws in elements of nutrition from the atmosphere; another draws up from the deep collars of the earth the mineral or inorganic constituents of plants. But these are not sufficiently abundant in earth that has been exhausted by hard cropping. Hence the necessity of manuring. Where most has been taken, more must be given back. As reasonably expect a profitable day's work from a starving man as a good crop from hungry ground.

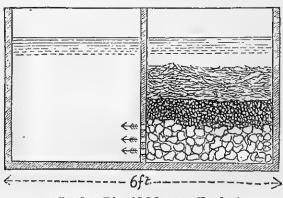

If you would reap bountifully, sow plentifully of manure. An obvious truism, some will say, but it is one which is forgotten every day nevertheless. Certain it is that almost every garden or field is cruelly underfed. But where is the food to come from? Wherever there is a road to clean, a ditch to scour, a farmyard or closet to empty, leaves or stems to gather together; these are the natural food of the earth. When we waste them, we rob the ground, and consequently lighten its produce. Treasured and wisely applied, they keep it in training for full fertility. Very much, however, depends on their application. Like ourselves, the earth thrives best on mixed diet, and needs bulk to fill it, as much as quality to enrich it. Hence the immense value of such *omnium gatherum* in the form of manure as can now be collected. As water forms the bulk of nearly all liquid medicines, so earth of various kinds forms the fittest foundations for all manures. It is the mixing medium and more, for turfy loam, in so far as it is turfy, is the sweetest food for plants. Every cultivator should instantly set to work to concoct a season's supply of food for the earth, if he has not got it ready before. Choose an out-of-the-way place for a huge heap of rubbish of all kinds. If possible, put enough hot dung and leaves with it to cause a gentle warmth. This is the cooking process which kills weeds, steams down the grossness of solids, and mellows the entire mass. If any sticks or stems are too hard for this mode of cooking, put fire through them, not to consume but to char them. This is easily done by smothering the fire with turves and a layer of earth. These charred remains form capital food for the earth, either given neat or mixed with other condiments. When the cooking is completed, saturate the whole mass with house sewage or liquid manure either from stable or cow-house. Thus treated, a heap of manure of the most nutritious kind may soon be provided and of sufficient size to satisfy the wants of most gardens.

D. T. FISHER.

LIQUID-MANURE SUPPLY FOR THE GARDEN.

A SMALL but regular supply of liquid-manure is indispensable to the well-managed garden, and though its use is often recommended for many things that good culture, soil, and water grow as well as we could desire, and its over-use is often a nuisance in the garden, yet, for all soft-wooded pot plants and for many a little crop or specimen in the open garden, the cultivator finds it a great aid. To induce a flowering habit in some plants, notably Pelargoniums, it is requisite that they should be grown with contracted pot room and a not over rich soil; then you induce that firm, stubby, and flowery habit so much the characteristic of good plant culture; whereas if you give a Pelargonium for "show" geranium, as it is commonly called) free pot room in a rich soil it "runs to leaf" and ragged coarseness of habit instead of flowering abundantly. But when we keep our show geraniums over the winter in that ripe and concise condition, so to speak, and the flower buds are all "set" and made sure of, then, if we have a clear supply of mild liquid-manure at hand, we add a deeper verdure to the foliage, and furnish a fund of acceptable nutriment to the flowers, by giving them a diluted dose of it twice a week. It is unwise and unusual to disroot, re-pot, or disturb plants shortly before their flowering; but very often just before they arrive at that stage the pots get full of hungry roots, and the supply of food is curtailed just when it is much wanted. The Cineraria, Fuchsia, Calceolaria, and soft-wooded plants generally illustrate this every year. Left to the well-nigh exhausted supply of their pots the flowering is free enough, but very often too short; whereas a few good soakings of liquid-manure, given when the soil is not too dry, strengthens the flowering in a very perceptible degree. Without doubt sheep droppings form the best material from which to draw

our supply of liquid-manure; they are also convenient, and may be had at hand in most country places. Liquid-manure so made we have always noticed to be the mildest, safest, and most grateful to the plants. It is generally procured by throwing a lot of manure at the bottom of a small tank, sunken barrel, or similar article, and filling it with water. When made and settled it is fit for use for a little while, but then the supply falls towards the dregs at the bottom, and the dregs are accordingly fished up; and thus it is that you so often see the pots where liquid-manure is used covered with a sediment alike nasty and detrimental to the health of the plants. This, and the fact that the tank requires to be cleaned out frequently and waited for till it is settled again, throw a few little awkwardnesses in the way of its use which renders liquid-manure an aid rarely resorted to even in many gardens which have been specially prepared for its use. All this would be obviated by making a little tank proper for it in the following way:—Let the tank be of slate—it is the best, most lasting, and neatest material—oblong in outline, and divided into two equal parts with a partition of slate also. Of course

Garden Liquid Manure Tank.'

it may be made of other material if you choose. The lower foot or so of this partition should be perforated with holes a few inches apart, and eighteen inches of rough gravel thrown in on one side. On that place an inch or two of fine gravel, and then the couple of barrowfuls of sheep's droppings, or whatever manure you may use, and finally over that pour the water. Thus the liquid will be nicely filtered at all times. The supply need not be cut short when you are putting in fresh droppings; it will be always free from sediment and clear. Place the tank in some handy position near the houses, or in the frames and pits; surround it with a slight brick wall, and cover it with a hinged wooden shutter, to keep out falling leaves, &c.; and liquid-manure will ever afterwards be at your convenience at all times.

One word more: always dilute it well. We once saw a fine batch of Chrysanthemums killed by getting a dose of strong and but slightly diluted liquid from the farmyard. The leaves were black next day, and the plants dead the following. Let it act as a caution. The manure should be as near the colour and clearness of bitter ale as possible.—*Field.*

THE ARBORETUM

THE MONTEREY CYPRESS.

(*CUPRESSUS MACROCARTA.*)

I OBSERVE that Mr. Barron, of Sketty, criticises my remarks respecting this lovely evergreen tree, and cautions planters, because he himself had induced a gentleman to plant a thousand of it, of which 999 died, and one only is left, which is doing pretty well. This, however, is no reason why others should not be induced to try again, as something might be learnt from so great a failure in an exposed situation. Mr. Barron does not inform us whether or not they were young, free-growing plants from the seed bed, or plants transplanted and well hardened, or plants that had been in pots a year; or if they had been well staked, mulched, and well protected by thickly-planted nurses; or whether or not they had the protection of a rough cage with a few stakes and evergreen boughs surrounding them till well established, or any other kind of simple defence against the cold blast, without which failure would be pretty sure to take place.

Mr. Barron states that there are some fine specimens of this cypress near the sea, which he himself planted. I have observed some fine plants of it myself not far from Sketty. That this cypress will

thrive in an exposed situation I could adduce proofs by the hundred. A gentleman who built a nice house near the sea a few years ago in a most exposed situation, said I wish you could give me a list of plants which I could place about my house that would withstand the driving and cutting winds to which we are subjected. I made out a list of such things as I had observed would live and get established, at the same time I cautioned him not to plant a tree or shrub, without well securing them immediately with stakes, mulching them, and sheltering them with plenty of common things planted thickly all round them as nurses, to be pruned in at first, to give room for the principal plants. Then I recommended him from year to year to thin gradually till all the nurses could be dispensed with. In such situations if people would stick in round about and between such plants as they wish to stand, plenty of large branches of furze, evergreen boughs, or any comatable materials, using thatched hurdles or open rough scantling nailed together as protections, they would succeed. Do not attempt to plant without some such defences, and do not choose luxuriant, free-growing plants, but rather such as have been a good deal exposed, once or twice transplanted, and from poor soil. My instructions in the case just alluded to were fully carried out, and complete success was the result, so much so that a brother of the gentleman just adverted to built a house and asked me to give him a list, as he wished to establish some good things, and, as much as possible, of an evergreen character. I gave him the names of all the things, and more, that I mentioned in my little statement on seaside planting, which Mr. Barron criticises, and amongst them *Cupressus macrocarpa*, a great favourite with most people; this succeeded perfectly, but without protection for a time it would not have thriven. My motto has always been—what you do, do well; you then get satisfaction. Indeed, without much care in the way of early protection, it is of little use planting good things near the sea. In November last, a gentleman, conversing with me, said he was pretty nearly tired of planting. He possessed a large extent of rough, uncultivated land, and wished to plant a portion yearly, but his losses were so extensive in dead plants that out of 100,000 of Scotch firs, many thousands of larch, chestnut, ash, and oak, which he planted last year, not a thousand were then alive, and those were stunted and made no growth. Surely, there must be something radically wrong somewhere in such a disastrous case as this. But there is besides; I have observed, a large extent of what may be termed sticking in of plants, not planting them; how can it be wondered at, therefore, that failures take place?

JAMES BARNES.

THE PINE.

Of the many marked adaptations of nature to the mind of man, it seems one of the most singular, that trees intended especially for the adornment of the wildest mountains should be, in broad outline, the most formal of trees. The vine, which is to be the companion of man, is waywardly docile in its growth, falling into festoons beside his cornfields, or roofing his garden walks, or casting its shadow all summer upon his door. Associated always with the trimness of cultivation, it introduces all possible elements of sweet wildness. The pine, placed nearly always among scenes disordered and desolate, brings into them all possible elements of order and precision. Lowland trees may lean to this side and that, though it is but a meadow breeze that bends them, or a bank of cowslips from which their trunks lean aslope. But let storm and avalanche do their worst, and let the pine find only a ledge of vertical precipice to cling to, it will nevertheless grow straight. Thrust a rod from its root shoot down the stem; it shall point to the centre of the earth as long as the tree lives.

I wish the reader to fix his attention for a moment on these two great characters of the pine, its straightness and rounded perfectness; both wonderful, and in their issue lovely, though they have hitherto prevented the tree from being drawn. I say, first, its straightness. Because we constantly see it in the wildest scenery, we are apt to remember only as characteristic examples of it those which have been disturbed by violent accident or disease. Of course, such instances are frequent. The soil of the pine is subject to continual change; perhaps the rock in which it is rooted splits in frost and falls forward, throwing the young stems aslope, or the whole mass of earth round it is undermined by rain, or a huge boulder falls on its stem from above, and forces it for twenty years to grow with weight of a couple of tons growing on its side. Hence, especially at edges of loose cliffs, about waterfalls, or at glacier banks, and in other places liable to disturbance, the pine may be seen distorted and oblique.

Other trees, tufting crag or hill, yield to the form and sway of the ground, clothe it with soft compliance, are partly its subjects, partly its flatterers, partly its comforters. But the pine rises in serene resistance, self-contained; nor can I ever without awe stay long under a great Alpine cliff, far from all house or work of men,

looking up to its companies of pine, as they stand on the inaccessible juts and perilous ledges of the enormous wall, in quiet multitudes, each like the shadow of the one beside it—upright, fixed, spectral, as troops of ghosts standing on the walls of Hades, not knowing each other—dumb for ever. You cannot reach them, cannot cry to them; those trees never heard human voice; they are far above all sound but of the winds. No foot ever stirred fallen leaf of theirs. All comfortless they stand, between the two eternities of the Vacancy and the Rock; yet with such iron will, that the rock itself looks bent and shattered beside them—fragile, weak, inconsistent, compared with their dark energy of delicate life, and monotony of enchanted pride—unnumbered, unconquerable.

Then note, farther, their perfectness. The impression on most people's minds must have been received more from pictures than reality, so far as I can judge; so ragged they think the pine; whereas its chief character in health is green and full roundness. It stands compact, like one of its own cones, slightly curved on its sides, finished and quaint as a carved tree in some Elizabethan garden; and instead of being wild in expression, forms the softest of all forest scenery; for other trees show their trunks and twisting boughs; but the pine, growing either in luxuriant mass or in happy isolation, allows no branch to be seen. Summit behind summit rise its pyramidal ranges, or down to the very grass sweep the circles of its boughs; so that there is nothing but green cone and green carpet. Nor is it only softer, but in one sense more cheering than other foliage; for it casts only a pyramidal shadow. Lowland forest arches overhead, and chequers the ground with darkness; but the pine, growing in scattered groups, leaves the glades between emerald-bright. Its gloom is all its own; narrowing into the sky, it lets the sunshine strike down to the dew....

And then the third character which I want you to notice in the pine is its exquisite fineness. Other trees rise against the sky in dots and knots, but this in fringes. You never see the edges of it, so subtle are they; and for this reason—it alone of trees, as far as I know, is capable of the fiery change which we saw before had been noticed by Shakespeare. When the sun rises behind a ridge crested with pine, provided the ridge be at a distance of about two miles, and seen clear, all the trees, for about three or four degrees on each side of the sun, become trees of light, seen in clear flame against the darker sky, and dazzling as the sun itself. I thought at first this was owing to the actual lustre of the leaves; but I believe now it is caused by the cloud-dew upon them,—every minutest leaf carrying its diamond. It seems as if these trees, living almost among the clouds, had caught part of their glory from them; and themselves the darkest of vegetation, could yet add splendour to the sun itself.

John Ruskin.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Replanting Forest Trees.—I have this winter cut down a plantation of about ten acres, which I want to replant as soon as possible, and I should be obliged if you would inform me what trees would be most suitable. The plantation originally consisted of Scotch and larch firs, with a few spruce and oak. All the Scotch and spruce and most of the oaks have at different periods been thinned out; of the remainder, the oak is decidedly healthier than the larch. The land is about 600 feet above the sea, north of the Forth, and the soil is light and not very deep. Shelter is much needed, and I am fond of game. Will the ground be sick of firs, and will it be necessary to wait some years before replanting, or can I do so next autumn?—J. M. [The ten acres of ground alluded to, which has been cleared of trees, should, if possible, be pastured during the coming summer. All loose branches, roots, and long herbage, now upon the surface should be burnt during dry weather in March or April, taking care to keep the fire away from the existing oaks or other trees worth being preserved. The ground may be planted next fall or winter; allowing the trees to be four feet apart, including the present trees, 2,500 plants will be required for each acre.—500 Scotch fir, 250 Austrian pine, 250 Corsican pine, 300 larch, 100 spruce, 100 silver fir, 250 sycamore, 100 Norway maple, 100 beech, 50 elm, 50 ash, 100 Italian poplar—total, 2,150. And for underwood and cover for game:—100 *Pinus montana*, 50 bay laurels, 50 privets, 50 red dogwood, 50 *Rhamnus Frangula*, 50 snowberry—Total, 350. As the surface of the ten acres will in all probability be somewhat undulated, and portions being more or less dry or damp, it will therefore be necessary that the planter uses his discretion in fixing on suitable places for each variety. All the firs may be what is termed "slit" planted, the plants varying from ten to fourteen inches in height. The hardwood and cover plants should all be "pitted," and to be three and a half to four feet in height when planted, as shelter and cover is speedily required. The land must be pretty good, judging from the fact stated that oaks thrive so well upon it.]

The Woods Alive.—The woods are all alive to one who walks through them with his mind in an excited state, and his eyes and ears wide open. The trees are always talking, not merely whispering with their leaves (for every tree talks to itself in that way, even when it stands alone in the middle of a pasture), but grating their boughs against each other, as old horny-handed farmers press their dry,

rustling palms together, dropping a nut or a leaf or a twig, clicking to the tap of a woodpecker, or rustling as a squirrel flashes along a branch. It was now the season of singing-birds, and the woods were haunted with mysterious, tender music. The voices of the birds which love the deeper shades of the forest are sadder than those of the open fields: these are the nuns who have taken the veil, the hermits that have hidden themselves away from the world and toll their griefs to the infinite listening Silences of the wilderness—for the one deep inner silence that Nature breaks with her superficial sounds becomes multiplied as the image of a star in ruffled waters. Strange! The woods at first convey the impression of profound repose, and yet, if you watch their ways with open ear, you find the life which is in them is restless and nervous as that of a woman: the little twigs are crossing and twining and separating like slender fingers that cannot be still; the stray leaf is to be flattened into its place like a truant curl; the limbs sway and twist, impatient of their constrained attitude; and the rounded masses of foliage swell upward and subside from time to time with long soft sighs, and, it may be, the falling of a few rain-drops which had lain hidden among the deeper shadows. I pray you, notice, in the sweet summer days which will soon see you among the mountains, this inward tranquillity that belongs to the heart of the woodland, with this nervousness, for I do not know what else to call it, of outer movement. One would say, that Nature, like untrained persons, could not sit still without nestling about or doing something with her limbs or features, and that high breeding was only to be looked for in trim gardens, where the soul of the trees is ill at ease perhaps, but their manners are unexceptionable, and a rustling branch or leaf falling out of season is an indecorum. The real forest is hardly still except in the Indian summer; then there is death in the house, and they are waiting for the sharp shrunken months to come with white raiment for the summer's burial.

SOCIETIES, EXHIBITIONS, ETC.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

We have great pleasure in announcing that the Rev. Mr. Hole will take the chair at the next anniversary dinner of this institution. Mr. Hole is the very best man that could be selected, and we are glad to record that the managers of the Institution have for once thought fit to select a chairman who is not a stranger to the art, and who has his whole heart in the cause. We think the result will prove the wisdom of the course pursued, and look forward for one of the most successful anniversaries ever held by the Gardener's Royal Benevolent Institution.

At the general meeting of this excellent charity, on the 11th inst., six new pensioners were added to the list, one polling the extraordinary number of 1,106 votes. The managing committee recommended the alteration of the objectionable figure £20 to £30, in rule 10, which was agreed to, and seems a step in the right direction. It would have delighted many if an alteration had taken place in rule 8. During the evening it, however, transpired that when the funded property amounted to £10,000 (it is now upwards of £8,000) the present managers will be ready to recommend that £20, instead of as at present £16, a-year should be given to each male pensioner. I was agreeably surprised to see a much greater number of gardeners at this meeting than on former occasions; and, from remarks that came from a good source, gardeners from certain parts of Middlesex and Herts show great interest in, and warm sympathy towards the association, the best evidence of which is, that many of them have joined it. This indicates a healthy, social tone, and I would say to gardeners generally who are not members of this charity, "Go and do likewise"—take part in alleviating the distress of indigent gardeners and their widows. I ask you, on behalf of such as are unable to help themselves, and if you are in a position to spare a guinea a-year, I am sure it will be well bestowed. Those, too, who, by the favour of a kind Providence, are in easy or affluent circumstances, I would remind that for all which they derive in the way of enjoyment in their gardens, that which is beautiful to the sight, fragrant to the smell—in short, whatever ministers to their luxury, their comfort, or their pleasure, they are, in a great measure, indebted to the skill and industry of the gardener. But the result of this is often a shattered constitution; therefore, I would say, give out of your abundance a donation to this deserving charity. In the words of the poet, let me say,

"Girdle not, ye rich, ye little know the cares,
The weight of the labours, and the skill,
That day and night are exercised, and hang
Upon the ticklish balance of suspense,
That ye may garnish your profuse regales
With summer fruits, brought forth by winter suns."

A MEMBER OF THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE ROYAL HORTICULTURAL SOCIETY'S SHOW AT
BIRMINGHAM.

A PUBLIC MEETING was held in the committee room of the Birmingham Town Hall the other day, for the appointment of a local committee, and for making other arrangements for promoting the exhibition of the Royal Horticultural Society in Birmingham in June next. Mr. Alderman G. B. Lloyd (ex-mayor), who occupied the chair, said that, in selecting Birmingham, the Society had paid a compliment to the town, and he hoped the inhabitants would appreciate it by making the exhibition a complete success.—Mr. T. B. Wright had much pleasure in moving that "The meeting having heard with satisfaction that the Council of the Society had accepted the invitation to hold their next country meeting in Birmingham on the 25th, 26th, 27th, 28th, and 29th June next, pledged itself to co-operate in all the arrangements which might be necessary to promote the success of this its first visit to the district." One duty which the local committee would have to discharge would be to raise a fund for providing special prizes, to supplement those offered by the Society. In other places where exhibitions of this kind had been held, a large sum had to be raised, in order to put the grounds in proper order. Nothing of the kind would be required in the present instance, for that would be undertaken by Mr. Quilter, and he hoped the railway companies would be as liberal on this as they had been on other occasions.—Mr. Councillor E. Tonks moved that, with a view to carry out the foregoing resolution, a local committee be appointed, consisting of noblemen and gentlemen, whose names are given, with power to add to its number if necessary.—On the motion of Mr. C. J. Perry, seconded by Mr. J. E. Mapplebeck, it was resolved that the Earl of Bradford be respectfully requested to accept the office of president, and his worship the Mayor of Birmingham that of vice-president of the committee.—Other officers were also chosen, when Mr. Hallam said that, notwithstanding the very excellent appointments just made, there would be much work to be done, which would require the services of a paid secretary, and he therefore begged to propose the appointment of Mr. Alexander Forrest. That gentleman had had considerable experience in connection with horticultural exhibitions, and a better selection, therefore, could not probably be made.—Mr. Councillor Lowe moved that a subscription be entered into for the purpose of raising a special fund to supplement the prizes offered by the Society. He trusted that a leading prize of £50 or £100, which had a decided Birmingham character, and which would be a novelty, might be given. Birmingham was noted for successfully carrying out great exhibitions of a national character, and he believed if the town and neighbourhood acceded to the proposal contained in the resolution they would have a thoroughly good prize list, and a successful meeting.—Mr. E. W. Badger said, they ought at least to raise in Birmingham as much as was contributed by the Nottingham people. There £700 was raised.—Mr. Marshall, one of the deputies from London, said himself and Mr. Richards had attended that day, in order to hear the views of those present. He said, the local prize fund should not be given, if possible, for any particular object, as that would interfere with the arrangements of the show. If a certain sum of money was placed in the hands of a responsible committee, they would be better able to divide it into prizes than if it was given by individuals for any particular hobby.—Mr. Richards stated that the council had had a preliminary meeting at South Kensington, to decide upon the question of admission to the show, and they thought of fixing 10s. 6d. as the charge for the first day; half-a-crown for the second day; a shilling for the third and fourth days; and a sixpence for the fifth. There would be a reduction of three shillings on tickets purchased beforehand for the first day, which would make the admission 7s. 6d. The subscriptions for the entire show it was thought should be a guinea. Subscribers of one guinea, it was suggested, should have three single tickets for the first day, and four for the second day; but he thought they would have to discuss that hereafter, as the privilege contemplated seemed rather too large. For a subscription of 10s. 6d. a single ticket of admission, available on all days, but not transferable, would be given. Tickets for the third and fourth days should be sold to manufacturers for their work people, in packets of not less than fifty, at a reduction of thirty per cent.—In reply to a question, Mr. Richards said the proposal as to admissions which he had read was merely a sketch, and at present in embryo only.—Mr. Wright next moved a resolution to the effect that every encouragement be given for the exhibition of horticultural implements and appliances, garden ornaments, and articles generally which are applicable for use in the several branches of rural economy. He said that at previous shows this department had not always been successful.—All the above resolutions were unanimously carried.—The directors of the London and North-Western Railway were to be asked to erect a temporary station at Witton Bridge for the accommodation of the show. At the close of the meeting it was stated that upwards of £130 had been subscribed towards the special prize fund.

Not all at once.—It is a mistake, therefore, I think, to start at the commencement of your home, or should it be in the prospective growth of charms. Your city home—when once the architect, and the upholsterer have done their work—is in a sense complete, and the added charm will lie in the genial socialities and hospitalities with which you can invest it; but with a country home, the fields, the flowers, the paths, the hundred rural embellishments, may be developed in a constantly recurring succession of attractive features. This year, a new sketch of shrubbery, or a new gateway on some foot-path; next year, the investment of an overhanging ledge with floral wonders; the season after may come the establishment of a meadow (by judicious drainage) where some ugly marsh has offended the eye; and the succeeding summer may show the redemption of the harsh briary up-hill that you have scoured into fertility and greenness.—D. G. Mitchell.

THE GARDEN IN THE HOUSE.

ROSE-BUDS IN AMERICA.

FLOWERS, or designs in flowers, says Mr. Peter Henderson, like numerous other articles of luxury, unmistakably have their fashions, which originate in large cities, and have their run there for a year or two until the particular design or particular flower is supplanted by others. Ten years ago graceful hanging-baskets were the fashion in New York, but after a year or two they were as common in the tenement of the mechanic as in the palaces on Fifth Avenue, the difference only being in the expense of the materials. Under these circumstances they could no longer be fashionable, and rapidly gave way to the more expensive rustic stand or Wardian case, which, being less readily imitated by people of limited means, is likely to continue longer fashionable. But the vagaries of fashion as to particular kinds of flowers are more singular. Twenty years ago camellia flowers were retailed at from fifty cents to a dollar each, and no piece of flower-work was thought complete without them. Now they are at a discount, and do not throughout the season average half the just named price. Now, Rose-buds, that then were not worth as much by the dozen as a single camellia, are now nearly of equal value, and some particular kinds even more so. One of the leading florists in the Broadway informed me that in the week ending December 2nd he sold one hundred buds of Maréchal Niel for as many dollars, for which he paid the grower fifty dollars. Tea Roses are required this season in every basket or bunch of flowers, and the bouquet-makers are nearly driven to their wits' end to get them. The fashion for Tea Roses has already spread to the country towns, and hardly a day passes that orders are not sent to us that we cannot fulfil. Church fairs, which did not formerly invest in expensive and perishable commodities, now find that the Tea Rose-bud for the button-hole is sought after by hundreds of purchasers. I was waited on, the other day, by the "flower committee" for a church fair in one of our suburban towns. The first item on their list was three hundred Tea Rose-buds. The wholesale price was twelve dollars per hundred, yet they were much disappointed that only one hundred, instead of three hundred, could be spared. The number of glass structures for growing rose-buds in the vicinity of Boston and New York, has probably been doubled during the past year, yet the price has advanced one-third. The kinds mainly grown are Céleste (carmine-purple) and Safranot (orange-yellow). The Maréchal Niel (golden-yellow) and Lamarque (white) are grown, but not so extensively as the Tea varieties, as they require greater age before they begin to flower, and, being climbers, flower best when trained to trellis-work. The large price paid for the buds of the former, however, will no doubt stimulate to its more general cultivation.

Natural Wreaths for Ladies' Hair.—Those who recommend the old but useful *Euphorbia jacquiniflora* for dressing hair are quite right, for it is one of the best subjects that could be grown for that purpose, provided a brilliant scarlet is required. We grow it by the dozen, especially for furnishing cut flowers for the dinner table, and so suitable is it for such purposes that it is really a matter for wonder it is not grown very extensively, instead of being met with in a few places only. There is another plant to which attention may be profitably directed in common with natural wreaths, and that is *Astilbe japonica*, more commonly known as *Spiraea* or *Hoteia japonica*. The feathery spikes of flowers of this, notwithstanding their light fragile appearance, stand well, and remain fresh for a very considerable period when placed under the most adverse influences, such as a gas-lighted and overheated room. They may, at all events, be depended upon for remaining perfectly fresh during the continuance of any ordinary ball or entertainment. The colour and character of the flowers admit of their being employed in conjunction with those of a large number of winter-flowering subjects. The flowers of the *Euphorbia* and *Astilbe* form most effective combinations either in the hair or upon the dinner-table. The two combined, with the addition of a few double Russian violets, are most popular here for the little glasses placed by the side of each guest. To make the most of the *Euphorbia*, the spike is cut up into lengths of about an inch each, and secured to thin strips of wood to keep them steady in the glasses. By this means one good spike will serve for filling five or six glasses. We of course contrive to place the bottom of the stem so that it touches the water; but if it does not the leaves should be removed and replaced with a fern-frond or a leaf or two of the *Astilbe*, as they show signs of exhaustion first.—A Head Gardener, in "Gardeners' Magazine."

THE TOWN GARDEN.

WALLS VERSUS WIRE FENCES.

The backs and fronts of third-rate houses in many of our recently-built streets generally present several kinds of objectionable excrescences which need not be. There is, it is true, no necessity for introducing at the back the stucco balustrading and plaster porticos, which in the fronts speculative builders consider absolutely necessary in order to make

Back Gardens as they are.

the rapidly run-up structures attractive to the kind of tenants they expect to secure. But, on the other hand, there can be no necessity whatever for making the backs hideously ugly, and, for want of a little architectural skill and discretion, thrusting into prominence certain features which ought to be made as inconspicuous as possible. Neither can there be any justifiable pretence for converting the little back gardens into a series of wells, by closing them in with nine-inch brick walls six or seven feet high, as is shown in the annexed representation, which embraces a view of the back of one row of houses and the front of another row just like it. These exhibit want of taste far more than did ever our old-fashioned houses, which were at least as good at the back as in front, and which pretended to be nothing more than plain houses. Times have, however, changed, and now crowded, unhealthy piles of bricks and mortar, covered with plaster, are made to assume the character of rows of palaces, and have to do duty for the beloved old structures; but what shall we say when we see that just as the new times call for stucco and balustrading on the front, they also call for, or, at least, allow, and that without protest or murmur, proportionate degradation of the backs? This must be evident to anyone approaching London by rail, from which untidy little yards and tottering walls, zigzag roofs, and accumulated absurdities are everywhere apparent. People don't care for back gardens, it is said; and why not? simply because, do what one will with them, it is impossible to make them interesting while their surroundings are so uninviting.

Now, "look on that picture and on this." What is the difference? In the first place, the latter shows back premises some-

Back Gardens as they ought to be.

thing like what they ought to be, with gardens which no one need be ashamed to enter. The stifling walls which hemmed them in have been removed, and light wire fences put up in their place, admitting of a better circulation of air, and, consequently, of better plant-growth. Occupants seeing that Nature steps in to their aid, take courage, and

thus, instead of flooded water-barrels and similar drawbacks, we get trim beds edged with tiles and with flowers, issuing from among a warm, fresh-looking mulching of cocoa-nut refuse. The withered shrub from the room-window has grown bright again when stuck into the ground. In Victoria-street, Westminster, last spring, were two patches of ground, each destined to bear half-a-dozen houses; they were wild and open, as such plots generally are, and were covered with a vegetation that astonished me, being much more robust than that usually met with in London gardens. It is evident, therefore, that if air and sunlight are freely admitted, good results will speedily follow. Even *Cupressus Lawsoniana* grows up like that in our illustration, and the tuft of New Zealand flax, which was wintered in the entrance hall, now attracts more eyes than those of the unlucky wight who once looked into his garden for fresh air. Presently up springs a little portable greenhouse, more trees and shrubs are planted, ivy begins to creep over the houses, and in time the whole character of the place becomes changed for the better. Here we have a chance of inspecting some twenty gardens on each side of us, all furnishing matter for emulation, which the close-wall system never could have done.

Backs of houses, treated in this way, would soon become as interesting as the fronts, and even more so—but when will builders help us in this matter? They ought to understand that making houses more healthy, by being more open at the back, will not only attract tenants, but will save the cost of the ugly walls, which do harm instead of good. They will find that open iron fences between the gardens will be much more ornamental than brick walls, and that at a mere fraction of the cost.

A. DAWSON.

MEMORIAL TO OUR GARDEN-LOVING POET.

The ever charming and genuine poetry of Cowper teems with delightful passages that always seem freshly perfumed with the delicate odours of the garden, and rich with the various hues of its flowers. We have only to turn to the immortal "Task" to find floral portraits touched off with an ease and truth that has never been surpassed, if indeed equalled. Who ever painted the spring glories of our favourite garden with such accurate and yet poetic touches as those in which he describes the laburnum, the syringa, the Guelder rose, the lilac? Take first the laburnum,

"Laburnum, rich
In streaming gold—Syringa, ivory pure."

Then comes the Guelder rose, an exquisite picture, dashed off with a few touches brilliant as the pen-strokes of Byron. He is contemplating with loving rapture its flower-charged upper branches,—

"throwing up into the darkest gloom
Of neighbouring Cypress, or more savage yew
Her silver globes, light as the foamy surf
That the wind severs from the broken wave."

Assuredly the true spirit of the nature painter is there. It is the genuine poetry of the garden.

Such happy dashes of the poet's brush occur continually in "The Task," and are ever redolent of the rich shapes and perfumes they describe. Southey says, in his admirable life of the poet, "the best didactic poems, when compared with 'The Task,' are like formal gardens in comparison with woodland scenery." Lovers of gardens ought to take an especial interest in Cowper, to whose memory it is intended to erect a memorial in his native place, Berkhamstead. It is to take the form of a noble stained glass window, which, if appropriately designed, will be a suitable tribute to his worth and genius, and could not be better placed than in the fine old church of the parish of which his father was for many years the worthy rector. Cowper himself was born at the Rectory House, Berkhamstead, and both his father and mother are buried in the chancel of the church. The cost of the memorial is estimated at about £300. Earl Brownlow, the Rev. J. W. Cobb, rector of Berkhamstead, and Mr. William Longman, of Ashlyns and Pater-noster Row, have formed themselves into a committee for carrying out this proposal, and they trust that public generosity will enable them to erect a memorial worthy of its position in the east window of the newly-restored church. Contributions will be received by any of the committee, or may be paid to the account of the treasurer of the Cowper Memorial Fund, at Messrs. Praed's, 189, Fleet Street, London. The following amounts are already promised:

Earl Brownlow, £10; Earl Cowper, £10; J. Robinson, Esq., £10; Rev. J. W. Cobb, £5; W. Cooper, Esq., £10; Mr. Finch, £5; Admiral G. Gambier, £5; Miss Gambier, £5; J. Haynes, Esq., £5; W. Longman, Esq., £5; Capt. Robinson, £5; Miss Robinson, £5; Dean of Westminster, £2. 2s.; Rev. J. and Mrs. Hutchinson, £2; Mr. Catherall, £1; Miss Halsey, £1.

THE SIX OF SPADES.

[WE exhume the following charming but, unhappily, unfinished story by Mr. Reynolds Hole, from the pages of the old *Florist*: as a tale of gardening and gardeners it is unique, and well deserves to be more widely known than it is.]

My Lord Dufferin, in his "Letters from High Latitudes," tells the affecting story of a conscientious cock, who, perplexed by the perpetual sunshine, and unable to discharge the vocal duties which seemed to ensue therefrom, eventually crowed himself mad, and put an end to his existence with his own wings, by abruptly flying into the sea. "As we proceeded north," he writes (the nobleman, not the fowl), "and the nights became shorter, the cock we had shipped at Stornaway became quite bewildered on the subject of that meteorological phenomenon, the dawn of day. In fact, I doubt whether he ever slept for more than five minutes at a stretch, without waking up in a state of nervous excitement lest it should be cockcrow. At last, when night ceased altogether, his constitution could no longer stand the shock. He crowed once or twice sarcastically; then went melancholy mad; finally, taking a calenture, he cackled lowly (probably of green fields), and leaping overboard, drowned himself!"

It is, I say, a sorrowful story, especially when we reflect that under happier circumstances, this cock might have reached a good old age, and seen his daughters laying peacefully around him, and his sons a fighting one another like anything.

Analogously, I go on to consider whatever would become of us gardeners and florists if we were sentenced to an everlasting summer, if our conservatories within and our gardens without were, day after day, and week upon week, to glow with undiminished splendour, and make the air heavy with exhaustless odours. Would not our eyes be dazzled into weariness, aching and wrinkling, as when in our early youth we overdid them with our new kaleidoscope? Would not our nostrils finally be enforced to entreat the intervention of our forefingers and thumbs, to supplicate the presence of our pocket-handkerchief, lest we should die of aromatic pain?

Our powers of appreciating the beautiful are finite, soon tire, and need repose. What appetites we bring home from the loveliest scenery! How thirsty we were at Tintern! How we rush from the pre-Raphaelite glories of the exhibition to our strawberries and iced cream at Grange's! How palatable the oysters, how creamy the stout, how delightfully appropriate the bread and butter, when we have attended a spectacle at the Princess's!

Hence, horticulturally, I can welcome winter with gladness, and can thoroughly enjoy its calm repose. I can, with perfect equanimity, bid farewell to my chrysanthemums (though they are four feet in diameter), and can pleasantly drink to our next merry meeting in the silver cup which they have won. I want no conservatory, gay with camellias, with the Epacris, the primula, and the rose; I desire to rest and think. I can bide my time, patiently and thankfully, until the spring-light wakes my cinerarias to bloom, and bids my hyacinths yield their poesy of fragrance. My appetite craves for no stimulants, and asks no artificial food. It desires to say grace, and to rest, that it may be hungry again and healthful, when nature shall prepare the feast.

If ever I grow weary, aweary of my leaflessness and clayitude, good winter hath two ministers, hope and memory, who never fail to cheer. I have but to close my eyes, and memory displays once more before me those brilliant banks of azaleas and rhododendrons which glowed last spring at Sydenham and "the Park;" I gaze again upon the grand geraniums of Slough; I scent the roses which brightened up the square of Hanover, and made the admiring Londoner forget his Thames. Or hope speaks musically of the future; points to those dear little cuttings, so bravely upright in their tiny thumb pots, so charmingly conceited at having roots of their own, and tells of their growth and glory.

And I never realise more pleasantly, or appreciate more gratefully, this welcome rest and happy thoughtfulness of winter, than at the meetings of our little society, which we call "The Six of Spades." Come with me, reader, into our club-room, and let me introduce you to the members.

That club-room on this occasion (for we vary our place of meeting) is my garden-house, a warm and cosy chamber, I can tell you, or what would happen to those seed-bags hanging around, or to those tubers of the dahlia, piled, dry and dormant, in the background? The adjuncts of the apartment might not, perhaps, impress any but a floral mind with an idea of beauty. There is a potting-bench beneath the closely-shuttered window, with a trowel protruding from such well-matured and mellow soil, that I have heard my gardener declare it to be "as rich as a plum-pudding." Hard by, two bulky bags of sand from Reigate lean lazily against each other, like two aldermen of extra corpulence going home after a Lord Mayor's feast. Beyond is a pyramid of boxes, with many a railway label on their green exteriors, to tell of the anxious miles they have travelled with pansies, and carnations, and cut verbenas, and roses, and dahlias, in the sunny days that are past. Then comes a solid quadrupedal desk, full of catalogues and secretaries' letters, and "Chronicles" and "Florists" good store. Next to it the painter's studio—a table with pots of green and white paint, and neat "tallies," and slim training sticks, and circular wire-work, balloons, and baskets of a dozen fanciful designs. Upon the whitewashed walls a pair of bellows appear to be discoursing with a "Brown's fumigator" on the best method of getting rid of aphides. A wrathful canary, roused from its slumbers, twitters expostulations from its cage, and wishes "The Six of Spades" at Jericho. Above the fireplace is a piece of broken looking-glass, before which I once saw an under-gardener attempting to shave himself with a new budding-knife, and making such grimaces of direful but unconscious ugliness, as would have established the reputation of clown on either side of this mirror, but deserving a better place, are some of Mr. Andrews's charming delineations of flowers and fruit—among the latter a bunch of grapes, once so lifelike and luscious to look upon, that they might have been the identical bunch which the American artist painted for his mother with such extraordinary power, that the old lady was enabled to manufacture from it three bottles and a half of most delicious wine; but now sadly disfigured by dust and smoke, and rapidly changing their complexion from pale Mucadines to Black Hamburgs.

And now all is in readiness for our conclave, and the members of our small society arrive. Before our blazing fire, which roars a hearty bass to the mirthful tenor of the kettle, is a table for our pipe and glass, behind that table a roomy garden seat, which will accommodate four of our party, and on either side the fireplace a spacious comfortable chair, the one allotted to myself as president, and the other to Mr. Oldacres.

Mr. Oldacres is the gardener at the castle, and a "grand old gardener," too, you will admit, as he takes off his overcoat (he has walked two miles through the park this winter's evening), and shows you six feet of humanity, so handsome and so hale that you feel proud of belonging to the genus man generally, and to the species Englishman particularly. Six feet high and straight as a Guardsman, though he has seen the chestnut trees of his great avenue in flower for seventy springs, Mr. Oldacres is a model of manly beauty, from his neat drab gaiters (our ancestors had calves to their legs, and knew it) to the crown of his "frosty pow." Was ever hair so silvery? Was ever neckerchief so snowy white? Was ever face (what a razor must he have!) so bright, so smooth, so roseate? If the French should ever take possession of this country, and compel us to adopt their unpleasant custom of osculating our male friends, I should first endeavour to overcome my repugnance by kissing Mr. Oldacres on both cheeks. There is a perpetual smile and sunshine on them, and in his clear blue eyes, as though he had lived always among things beautiful, and their exceeding loveliness had made his heart glad. What pyramids of pine-apples, what tons of grapes and figs and peaches, what acres of flowers, tender and hardy, those hands have tended! The duke, his master, denies him nothing, and horticultural novelties and floral rarities (things which you and I, my friends, sigh for, and save up for, and speak of with "bated breath," and possess only in our *Midsummer Nights' Dreams*), these come to the castle by the boat-load, or travel by the rail on trucks! When you see his soil-yard you imagine that sappers and miners have been at work for weeks, and that an army is about to entrench itself within those

multitudinous earthworks. As for his "houses;" houses with enormous tanks, wherein the Royal Lily, Victoria, is waited on by the beautiful Nymphaeas; houses for orchids, for New Holland plants, for ferns, for fruit, and forcing; his houses of every size and style, from the dingy old lean-to, with its heavy timbers and its tiny, discoloured panes, to the grand conservatory, with its spacious dome, transepts, aisles, broad walks, and sparkling fountain; of these there is no time to tell. Less need, inasmuch as he, whom I now introduce to you, derives not his happiness from his vast material, his unlimited privileges and rare resources, but from his own good and grateful heart, which recognises God's love and power in all the glorious works around him, and sings

"Non nobis, Domine, sed Nomini tuo."

for all the sweetest joys of life.

Give the worthy gentleman, for gentleman he is in mind and mien, one of those long clean Brosely pipes. "My dear young Marquis," he remarks, as he fills and lights it, and the pretty little rings of silvery smoke rise upwards from the ample bowl, "My dear young Marquis brought me years ago, from Germany, a meerschaum, beautifully carved, in which you might almost boil an egg; and my lord in the Guards, and my lord at Oxford make me presents from time to time of such cigars as I don't suppose are to be bought for money; but my meerschaum goes out, when I begin to talk, unless I suck at its amber mouthpiece like a greedy child at a piece of barley-sugar; and the fire of those huge regalias draws so near to my nose, that I grow quite afraid of it; and, in short, I never enjoy tobacco so much as when it comes to my lips, coolly yet quickly, through these long cleanly tubes, and waits for me patiently, as now, through my tedious old man's sentences."

You would like to hear him respond, I am sure, when we drink his health as our "King of Spades," rapping the table with such strong and sudden earnestness as to bring the canary, just hoping to renew his slumbers, very summarily off his perch. "Sixty years ago," he said in the course of his little speech at our last meeting, "I was wedding the castle walks. Many and pleasant and prosperous have been my days since then; and if I were constrained to begin life anew I would ask that it might pass as heretofore. But I have no yearnings, though much thankfulness, for the past. There is mildew among our roses here, my friends, and bitter frosts, and dreary sorrowful storms. I hope that I do not deceive myself in thinking" (and here he spoke with such a sweet humility as filled mine eyes with tears) "I trust that I cannot be wrong in believing that, year by year, as I grow older, I draw nearer to a garden of perfect beauty and eternal rest, a garden more glorious than that which Adam lost, the Eden and the Paradise of God."

There was an interval of thoughtful, healthful silence, after Mr. Oldacres had spoken; and we too, my readers, will pause here, if you please, before I introduce to you another member of our club, whom I hope you may like as much as I do,—my young friend, Mr. Chiswick, from the hall. S. R. H.

(To be continued.)

French Peasant Fund.—M. Drouyn de Lhuys in reference to our aid to the French Peasants, says: "I mention England first. Her neighbourhood, her many relations with us, her liberal and intelligent practice of collective assistance, all mark her place in the first rank. Two great societies formed in London took the direction of this propaganda, which soon extended over the three kingdoms. Numerous meetings resounded with the warmest expressions, which found an echo in the whole Press. How greatly I regret, gentlemen, that I cannot here enter into the details of all the ingenious combinations and persevering efforts of which I was the witness or the confidant. Subscriptions flowed in from all parts, and testified both to the wealth and to the unisonance of this opulent country. What was to be done with these abundant resources? An equitable distribution must be made, and personal services completed the work of liberality. Delegates offered themselves to visit the ruins of our villages, and to distribute assistance to the impoverished agricultural population. Brave as soldiers, zealous as missionaries, punctual as accountants, on their return they drew up with wonderful accuracy the balance-sheet of this new class of commercial transactions, which consists in always giving and never receiving back. You all unite with me, gentlemen, in the solemn expression of gratitude which I offer in the name of French agriculture to so much and such generous devotion. As our husbandmen and our fields have been its principal object, it is for us to act as the interpreters of their gratitude."

HIDDEN WEALTH.

WHILE many go to great expense in allowing certain artists in plaster to embellish their grounds with huge masses of artificial rock, made of old bricks and cement, and while many more are satisfied with the old bricks themselves, accompanied by clinkers and a great variety of offensive rubbish, very few trouble themselves about the rock treasures that often lie beneath the sod. Considering the large sums that are spent in sham rocks, &c., and the vast superiority in every way of natural rock, masses of it are as valuable as golden treasures to those who care for the picturesque in garden or park scenery. The accompanying illustration gives a feeble notion of one of the rocks that a friend of ours has succeeded in unearthing. The place originally was somewhat liberally embellished with rock on surface; but our friend is not easily satisfied with rocks; in fact, he is like those "boys" out West who hunt for gold mines for years at a time. What tool he does his "prospecting" with, we are not certain; but by some means he ascertains the presence of ten feet of sand by the side of one huge mass of treasure. Then, by digging

Unearthed Rocks in a Sussex Garden.

out a mass of earth, he can form a beautiful gorg between two flanks of rock that would reduce the cement-rock artist to despair. And by clearing away the earth from the flanks of that nose of rock that just projects above a grassy knoll, he will discover beautiful wrinkles and other charms in it. Thus by a little persevering poking and digging has been produced a scene as striking and interesting as many in an alpine country, and one which offers such a variety of aspects and positions that every kind of hardy plant may be grown on it in the best manner, and arranged on it with the happiest effect. The subject is of the highest importance to the many who have places on a rocky base, who should be glad that this most precious stonework may be brought to light, unlike the treasures

"The dark unfathomed caves of ocean bear."

Soluble Sulphur and Gishurst Compound.—In a recent number of the *Illustration Horticole*, it is stated that M. Diricq, conductor of the manufactory of jet, at St. Pierre, near Brussels, is offering for sale a new product of special interest to horticulturists, namely, sulphur rendered soluble in water; a solution which is said to have been hitherto thought an impossibility. In this shape it is recommended as a sovereign application for the destruction of moulds, Oidium, Puccinia, *Aecidium*, and the whole host of microscopic fungi; nor are insects and their larva less subject to its power; and it is truly added that if its effect is at all equal to that of sulphur in powder, it must be regarded as a valuable discovery. It has been said, "things that are impossible rarely come to pass." Here we are fortunate enough to have the exception, not once but twice—once, the product M. Diricq has discovered; and already years ago, by the compound with which all horticulturists are now familiar under the name of Gishurst Compound, the discovery of our own talented countryman, Mr. Wilson, which is neither more nor less than sulphur-soap.—A. M.

THE AMATEURS' REMEMBRANCER.*

Flower Garden and Shrubberies.—While the weather continues open and mild, commence pruning and thinning roses, such as the different varieties of Provence, moss, hybrid Chinas, and others, leaving perennials till later in the season. Climbing roses on poles, against the walls of buildings, may also have their shoots thinned out, and if the poles are in any way decayed let them be replaced by fresh ones. Get all hardy roses planted as soon as possible, taking care that the situations in which they are to be placed, are in good condition to receive them. Standards, as soon as planted, should be tied to neat stakes, and their roots should be well mulched with rough stable manure.

Hardy Fruit and Kitchen Garden.—Wall trees, prune and nail and free standards from moss, by scraping it off their stems, afterwards painting them with thick lime-wash, the unsightly colour of which may be toned down by means of soot mixed with it. Where apple trees are infested with American blight, the limbs and trunk should be carefully divested of their loose bark, and all places where the insects have formed excrescences round knots, or where they have otherwise secreted themselves, should be pared off smooth with a sharp knife, and dressed with a wash, consisting of quicklime, flour of sulphur, and lamp-black. It should be applied with a strong painters' brush.—Fruit trees of all kinds still plant where necessary, keeping the roots near the surface and mulching with rough dung. Let the pits in which the trees are placed be sufficiently large to allow the roots to be spread out in all directions to their fullest extent.—Currants and gooseberries prune now; and dig, or rather fork, the ground over between the rows, giving it a good dressing of well-rotted manure, and drawing a little of the surface soil from under the bushes, and burying it in the middle.—Raspberries prune and tie.—When the weather is wet, prepare pea-sticks, and other kitchen garden requisites.—Dig up or trench all ground, as it gets free from crops. Stir the surface between cabbage plants and other winter and spring greens.—Forward a few ash-leaved kidney potatoes in boxes to be planted out hereafter in borders, and, where there is convenience, a few peas might also now be sown on strips of turf, under glass, to be hereafter placed in a row along the bottom of some south wall, protecting them a little at first by means of spruce fir branches.

In-door Plant Department.—Climbers in conservatories, prune, cutting back freely all that obstructs light.—Plants in bloom must be well attended to with water; use fire-heat as sparingly as possible, but do not allow the temperature to fall below 40°. In-door plants generally, except such as are in flower, should be kept rather on the side of dryness at the root; but when water is really required, give sufficient to thoroughly moisten the ball, applying it in a tepid state, and at this season always in the morning.—Introduce into the forcing pit at intervals of about three weeks or so, successions of hyacinths and other bulbs, Azaleas, Deutzia gracilis, Daphnes, roses, and other things of which there may be a stock.—If aphides attack cinerarias or calceolarias, fumigate with tobacco; and examine heaths and similar plants to see that they are not suffering from mildew; if so, dust immediately with flour of sulphur.—Pelargoniums, tie out, and give them air on all favourable occasions.—Re-pot such as require it in a compost consisting of good, friable, turfy loam, two parts, and thoroughly rotted manure and leaf soil one part each, adding silver sand, and well draining the pots.—Plants in cold pits should be kept as dry as possible, as wet and damp are even more injurious to them than frost. Air should be given them by tilting or drawing off the lights every mild day, between, say, ten and three o'clock; but they should not be open later than the last-named hour, and they should be covered with mats or something of a similar character every evening between four and five o'clock, if there are any symptoms of freezing. Frequently examine the plants, and keep them free from decayed leaves; the surface of the soil in the pots should also be kept clear of moss. Watering is a very important point; at this season scarcely any is required, as the moisture of the pit is generally sufficient. What is absolutely needed must be given in the morning; such pots as show indications of damping, surface with dry earth.

In-door Fruit Department.—Pine-apples intended for starting next month, should be kept rather dry, and in a temperature of 65° to 70°. Keep successions growing on without check.—Peaches and nectarines in bloom must have air whenever it can be given, and the temperature should not exceed 55°. Disbud sparingly, and fumigate from the first appearance of green fly.—Strawberries, keep near the glass, and endeavour to have their flower-stalks a little in advance of the foliage by keeping the plants at first starting rather on the side of dryness; let them have air on all favourable opportunities.—Early viney, keep about 60°, with a moist atmosphere, until the vines come into flower, when syringing should cease for a time, and the temperature should be increased some ten degrees or so. Ventilate every day when the weather will allow the sashes to be opened. Pot vines should be liberally supplied with clear manure water as soon as the fruit is set.

The Danger of Gas.—George Johnson, gardener to Mr. Hermitage, of West Hill, Wandsworth, has died from the effects of a gas explosion which took place in his employer's house. It was suspected that there was a leakage of gas somewhere in one of the rooms, and, in order to discover it, Johnson applied a lighted candle to the gas-tellur, when a terrific explosion took place, rendering him insensible, and burning him so much that his case from the first was pronounced hopeless. He died on Thursday week in St. George's Hospital.

* Complete monthly calendars, written by some of our ablest gardeners are published in THE GARDEN in the first issue for each month.

COVENT GARDEN MARKET.—January 27th.

Flowers.—Prominent among these Azaleas may be named, both in pots and as cut blooms; Acacias; Astilbe (*Spiraea*) japonica; Begonias; Calla aethiopica, cut and in pots; Camellias, cut blooms and in pots; Christmas Roses; Cinerarias; Hyacinths; Tulips; Narcissus; Snowdrops; and Crocuses; charming examples of Cyclamen; Deutzia gracilis, one of the best of our little shrubs for forcing; Echeveria heterophylla; Euphorbia; several kinds of Heaths; Lily of the Valley; Mignonette; Pelargoniums, both zonal and show varieties in pots and cut; Poinsettias, with wonderfully fine scarlet bracts; Primroses, both common and Chinese; cut Roses; cut flowers of Tropaeolum; Violets; and Wallflower. Among berry-bearing plants we noticed Solanum and Ardisia, both in excellent condition.

Prices of Fruit.—Apples, Dessert, 1s. to 3s. per dozen.—Cobs, per 100 lbs., 6s. to 6s.—Filberts, per lb., 8d. to 10d.—Grapes, per lb., 3s. to 8s.—Lemons, per 100, 7s. to 10s.—Spanish Water Melons, each, 2s. to 5s.—Oranges, per 100, 6s. to 10s.—Pears, per dozen, 3s. to 6s.—Pine-apples, per lb., 4s. to 8s.—Pomegranates, each, 4d. to 8d.

Prices of Vegetables.—Artichokes, green, each, 6d. to 8d.—Asparagus, per 100, 8s. to 10s.—Beet, per dozen, ls. to 2s.—Broccoli, purple, per bundle, 10d. to 1s. 3d.—Brussels Sprouts, per half sieve, 2s. to 3s.—Cabbages, per dozen, 10d. to 1s. 3d.—Capseums, per 100, 1s. 6d. to 2s.—Carrots, per bunch, 5d. to 7d.—Cauliflowers, per dozen, 2s. to 6s.—Celery, per bundle, ls. to 2s.—Chillies, per 100, 1s. 6d. to 2s.—Cucumbers, each, ls. to 2s.—French Beans, new, per 100, 3s. to 4s.—Herbs, per bunch, 2d. to 4d.—Horse Radish, per bunch, 3s. to 5s.—Leeks, per bunch, 2d. to 4d.—Lettuces, per score, 1s. 6d. to 2s.—Mushrooms, per potte, ls. to 2s. 6d.—Onions, per bunch, 2d.—Parsley, per bunch, 2d. to 4d.—Radishes, per bunch, 2d.—Rhubarb, per bundle, 1s. 6d. to 2s.—Salsify, per bundle, 9d. to 1s. 3d.—Scorzonera, per bunch, 9d. to 1s. 3d.—Seakale, per punnet, 1s. 6d. to 2s. 6d.—Shallots, per lb., 8d.—Spinach, per bushel, 3s. to 4s.—Tomatoes, per small punnet, 3d. to 6d.—Turnips, per bunch, 3d. to 6d.

Honolulu.—This is one of the most charming spots in the world, and seems destined by nature for a watering-place. It is not big enough for great mountains, broad rivers, or waterfalls. But the curious volcanic craters that partly girdle it give it a weirdness of aspect that makes the outline of the coast very striking; the thickly-wooded hills of the interior throw out green spurs toward the sea or descend upon dark gorges, and the level land is in part a garden already, and only wants culture to become one everywhere. Nowhere except in Ceylon have I seen such luxuriant vegetation, and the skill of the gardener has done more here than in the Indian islands. Every fruit that grows in the warmer parts of Asia finds a home in Honolulu; and many glorious Japanese flowers, waxen-leaved lilies of every hue, and delicate-textured ferns, have already been naturalized. Then the climate is delicious. I had expected a moist, stifling atmosphere, like that of a hot-house; but the prevailing wind gets dried in blowing over the hot volcanic rocks, and the air is as buoyant and bracing as in the hill-ranges of Australia. I can imagine Anglo-Indians coming here to recruit, though the thermometer never falls below 65°, and is at times twenty degrees higher.

Ivy Edgings.—The walls in the kitchen garden here are edged with dwarf ivy, which is very much admired by people who come to see our place. When first planted, the edgings were only nine inches wide, but now they are from twelve inches to eighteen inches. Twice a year they require "clipping" with a pair of shears, just as we do grass edgings, and the top should be kept level, sometimes with a pair of shears, and sometimes with a pocket-knife. I am of opinion that ivy stands the test and wear of a large garden better than box; at any rate, I have found it so. Neither do I find that it harbours anything like the amount of slugs which box does; and, added to that, it requires much less labour to keep it in order when once it is fairly established. For garden walls I have a great abhorrence of dead edgings, no matter of what design or material they are made. They might possibly be tolerated in neighbourhoods like that of Wolverhampton, or other "black countries," where it is difficult to get vegetation of any sort to thrive; but dead edgings in a garden, where there is a pleasant atmosphere, are really too bad.—W. Miller, Combe Abbey.

Part I. of THE GARDEN, containing 6 Numbers and upwards of 80 Illustrations and Plans, is now ready, price 2s., and may be had through all booksellers and newsagents, and at the railway stalls. Post free from the Office, sent flat between boards, 2s. 6d. Readers who may find it difficult to procure the numbers regularly through the newsagents or booksellers, may have them sent direct from the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance. THE GARDEN is sent to subscribers by Friday evening's post. All the back numbers of THE GARDEN may be obtained from the office, and through all booksellers and newsagents.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

"This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—Shakespeare.

THE FRUIT GARDEN.

RE-GRAFTING WORTHLESS FRUIT TREES.

The accompanying woodcut clearly illustrates a very excellent practice which we would highly recommend. Fruits—pears in particular—are strangely affected by different soils, localities, aspects, &c. A fruit may be found to be extremely good in one locality, and worthless in others. Thus, sometimes after taking great care in planting fruit trees, and after growing them and training them for many years, until they have become good specimen trees, so far as fruit is concerned, they have turned out to be but vile cumberers of the ground. Many, doubtless, have proved the truth of this assertion, and yet have hesitated to destroy their trees because of the beauty of their appearance and the blanks occasioned by so doing, years being required to again refill the space thus left bare. The plan now recommended, however, obviates all disappointment; and all that is necessary to be done is to re-graft as our illustration indicates. Nothing is simpler or more easily accomplished, and it is astonishing how soon a tree is thus refurbished and in full bearing condition after being grafted. Some forty or fifty handsome pyramidal pear trees about twelve feet high were thus cleverly manipulated by Mr. Barron, in the gardens of the Royal Horticultural Society at Chiswick in the spring of 1870. The success attending the operation has been so great, that in two years many of these trees presented as handsome an appearance as they did before they were grafted.

The advantages of the process may therefore be summed up thus:—

1. It enables us within two years, or little more, to obtain a full sized fruitful tree of a new variety, which otherwise could only have been done at the expense of planting and training a young one for ten or twelve years.

2. Double grafting on a well-seasoned stock assists the fruiting properties of many shy bearers.

The method of procedure is simple, and now is the time to set about it. First select sufficient grafts—say, one three inches long for each branch of the tree to be operated upon—

and lay them in, in gardening phrase, "by the heels" in some border until required. Selecting the scions now will reward them and allow the stock to get a little in advance of the graft, which is desirable. The stock itself may now be cut back, i.e., the branches to where it is intended to re-graft them, as shown in the representation—the bottom branches—at, say, one foot from the stem, and the top ones shorter, so as to gradually taper to two or three inches. Cut off all spurs in the ordinary way, to prevent confusion.

In the beginning of March the grafting may be commenced; common cleft or whip grafting being the best. Tie the grafts and clay up in the ordinary way. As soon as they seem to have fairly "taken," pay particular attention to their ties, in order to see that they do not compress the graft too tightly. Furnish each shoot with a firm stake to prevent its being blown off, for being exposed to so much wind it is apt to be displaced. If the scions push away very vigorously it is advisable to stop them, so as to enable them to gain strength at the point of union. Train and prune afterwards as on ordinary occasions.

We will, in a future number, give a list of pears very commonly to be found which ought in this country to be re-grafted. In numerous gardens much good may be effected by re-grafting old trees. In fact, there is no process more needed in our fruit gardens.

PYRUS.

THE FRUIT GARDEN FOR FEBRUARY.

BY WILLIAM TILLERY, WELBECK.

Pyramidal Pear Tree Re-grafted.

I am afraid not ripened well, owing to the expense of planting and training the young trees. The pruning and tying of raspberries, if not already done; the ground should only be lightly dug between the rows, but they will flourish with a good amount of rotten manure as a top-dressing.

Early Vinery.—As soon as the grapes in the early-house are set, thinning must commence before the berries get to the size of small peas. A night temperature from 60° to 65°, with an increase in the

daytime by sunheat to 75°, will have to be maintained. The giving air to early vineries in February is an operation that must be carefully performed, for in frosty, windy weather, the sun often comes out hot, and the foliage gets scorched, or injured by cold draughts if the air is not given with discrimination. Other late vineries must now be prepared for starting to keep up the rotation. The late grapes, such as Alicantes, West St. Peter's, Trebbiano, and Lady Downes's Seedling, will, if cut off and put into bottles of water, keep nearly as well as on the vines. The best way to keep them is in a room fitted up for the purpose, with wooden racks to place the bottoms of the bottles on. Iron rods are stretched on the racks, with a small bend every ten inches, in this way, ———, for the necks of the bottles to rest in, and the angle must be enough for all the bunches to hang clear when they are put in the bottles.

The Early Peach House.—The fruit will now be set in the earliest house, and syringings morning and evening will be required in favourable weather. Attention should likewise be bestowed on the thinning of the fruit, where they are set thickly, but this rarely happens when forcing commences so early. The dis-budding of the shoots is a process best performed by taking off only a few of the strongest at different times, so as not to give a check to the roots. The temperature at night may be maintained at about 60°, with a rise to 70° by day, and by sunheat 6° or 8° higher. Green-fly will begin to make its appearance, and the infected shoots must be picked off; but fumigation with tobacco will have to be resorted to at the last. The old system of fumigating hot-houses with the operator inside the house is now exploded, and it was a cruel infliction on young gardeners and others, who could not stand tobacco smoke. When a youngster, I was myself, on one particular occasion, engaged in the operation, and having stood the smoke as long as nature would permit, I shut the door and "bolted," but was sent back again by my master with the consoling remark, that I might "gang yet to a waur place." Some of the new patented fumigators are very efficient for the purpose, for, by making a hole in each door of the house for introducing their nozzles from the outside, the house can be soon quite filled with smoke, and kept so for any time required.

Fig House.—Figs should be kept well watered and syringed, with the night temperature at about 60°. When the young shoots have grown to the length of four or five joints, the terminal buds must be picked out, to encourage the formation of a second crop.

Cherry House.—The temperature must be kept low, from 40° to 50°, with plenty of air given on favourable occasions, until the fruit is set. After that they will bear more heat, with frequent syringings overhead till the fruit colours.

Strawberries.—Occasional batches will want to be introduced into the pits or forcing-houses according to the consumption required. When sufficient fruit has been set on a truss, the rest of the blossoms should be picked off to strengthen the fruit left on. Liquid manure, if used twice a week, will help the fruit to swell, but it must be discontinued before the fruit begins to colour.

Cucumber and Melon House or Pit.—The sun will now be more powerful, and therefore more favourable for forcing cucumbers and melons. A night temperature from 60° to 65° is not too much, and the day temperature, by sunheat, may range to 80°. Maintain plenty of moisture on the pathways and plants, but beware of scalding draughts of steam by dashing water on the pipes or flues. Another sowing of seed may be made to supply the general stock of plants, for gardeners always find a good many friends begging cucumber plants in March and April to plant in their frames.

Tomatoes.—This excellent fruit, if sown in the beginning of February and pushed on in heat, will ripen good crops in pots as early as May or June. I find the dwarf Orangefield the best for this purpose. The new sorts, the Trophy or General Grant, do not fruit so freely, and are later in bearing.

THE PINERY FOR FEBRUARY.

BY JAMES BARNES.

At no time throughout the year must there be any standstill work in the cultivation and production of this noble fruit, if it is intended to have it well finished and in perfection. Succession plants should have a little more heat as light increases. A portion of the finest plants should be shifted into the pots in which they are intended to be fruited; the bottom heat should be soon to, turned, and new materials added, in order to maintain a kindly growing root-temperature from 80° to 90°, and the atmospheric heat should be raised to 65° by the middle of this month, still gradually increasing the temperature as March approaches; syringing moderately only on very fine, mild, quiet days; and shut up soon in the afternoon, charging the atmosphere moderately with humidity. Suckers should be taken off old fruiting stools with a

piece of the old stem attached to them, and potted at once. This keeps them firm in the pot, and affords some nourishment. Never allow suckers to lie about to dry and harden for weeks, a practice which gives a six months' check in their progress. If succession plants are well cultivated, a few months' luxuriant growth will produce large and strong suckers, which should be cut off, and potted directly the fruit is cut, no matter what time of the season that may be. Old and long-growing plants will never ripen off good, well-swelled fruit. Of course, suckers taken off throughout the winter months do not make so luxuriant, quick growth as those taken off from June till October. As to potting or shifting, pines do not require such operations being performed so often as old growers used to recommend. Large, strong suckers, of course, require to be placed in pretty good-sized pots—say, from seven to nine inches—and then they only need one more shift, and that at once, into their fruiting pots. The best fruiting plants should at no season of the year be more than from ten to fourteen months of age, or they will not produce noble fruit, or swell it to perfection. If any favourite variety is wanted to be much increased, pot the old stools, place them in a very strong heat, and they will afford abundance of suckers; at the same time, when the old stalk or stem is pretty ripe and firm, as there is at the base of every leaf a bud, those buds may be scooped out with a piece of the stem attached, and placed in pans, in the same way as potato sets are treated, covering lightly with loamy, sandy soil, and charcoal dust. Set them on a kindly bottom heat, and any quantity of plants may be thus obtained. Fruiting pine plants require more attention the first three months of the year than during the whole year afterwards. Fruit now finishing swelling should have water entirely withheld at top and, if possible, be lifted out into a light, airy situation, close to the glass, on to a dry shelf or end pipes, &c. They should not be allowed to get dry; neither must they be permitted to get in the least degree soddened. Systematically apply tepid, clear manure water to the roots, and syringe gently the pots and base of the plants; and charge the atmosphere with genial humidity, increasing it as the days and light get longer and stronger at night to 70°, or a little more. Of course, by sunlight and on light days the temperature may be allowed to run up to from 80° to 90°, admitting air, but by all means avoiding draughts. Pine-apples now in bloom require particular care in maintaining a kindly and rather dry, warm atmosphere; but they must not be allowed to get dry at the roots, or else abortion in some shape or other will be the result. After the blossom is set—a process which takes but a few days—treat it all respects as for fruit swelling, as stated above. Fruiting plants just started, or about starting, require nice attention. They should not be allowed to get dry at the root, or diminutive growth will take place; syringe their base moderately on fine days, charge the atmosphere with a reasonable amount of humidity; use a moderate amount of heat, and they will show up, bold, strong, and perfect in shape, and in their turn will require the treatment recommended for plants swelling fruit, as before described. The next batch of fruiting plants should now be collected together, if not already done; the bottom heat should be renewed, and other requirements attended to, with an increase of heat and humidity; giving air freely, to give them time to start into fruit strongly and boldly. A man who can produce good and desirable fruit from January to June in abundance is a real pine grower. As is well known, strict, persevering attention must be fully carried out without check or lack, in order to achieve that desideratum. Early spring and early summer production is always of greater value than that of autumn and winter, when pines should be produced only in moderate quantities.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Madesfield Court Grape.—I have to-day cut my last bunch of this variety, and from what I now see it has fully borne out the character given to it by the Royal Horticultural Society. Mr. S. Simpson, of Manchester, a very good judge of grapes, assured me a few days ago that a bunch of this sort, which I gave him, after hanging in a dry place, but still moderate in temperature, kept for five or six weeks amongst other thin-skinned varieties, and at the end could not be surpassed in flavour. I have it very fine in colour and large in the berry. I am sorry I have not more of it, on account of its excellent quality. I am devoting a house about forty feet by eighteen feet to its cultivation. It has a good constitution, and I have no hesitation in stating it to be a very desirable variety to grow.—JOSEPH MEREDITH, *The Vineyard, Garden, Liverpool.*

A New Way to "Make" Fruit-Trees.—A passage in Darwin's "Naturalist's Voyage" (1831), which we met with the other evening, shows that the practice for which Mr. Hutchinson, of New Hampton, U.S., has lately taken out a patent, or a system very near it, is common in some parts of South America:—"In Chiloe," says Mr. Darwin, "the inhabitants possess a marvellously short method of making an

orchard. At the lower part of almost every branch, small, conical, brown, wrinkled points project: these are always ready to change into roots, as may sometimes be seen, where any mud has been accidentally splashed against a tree. A branch as thick as a man's thigh is chosen in the early spring, and is cut off just beneath a group of these points; all the smaller branches are lopped off, and it is then placed about two feet deep in the ground. During the ensuing summer the stump throws out long shoots, and sometimes even bears fruit. I was shown one which had produced as many as twenty-three apples, but this was thought very unusual. In the third season the stump is changed (as I have myself seen) into a well-wooded tree, loaded with fruit. An old man near Valdivia illustrated his motto, "Necesidad es la madre del invento," by giving an account of the several useful things he manufactured from his apples. After making cider, and likewise wine, he extracted from the refuse a white and finely-flavoured spirit; by another process he procured a sweet treacle, or, as he called it, honey. His children and pigs seemed almost to live, during this season of the year, in his orchard."

The Inepuisable Strawberry.—M. Mabille, of Limoges (Haute-Vienne), has just made a discovery which we consider very important, if its results at all correspond to its promises. He has obtained from the seed of the strawberry, *Ananas du Chili*, crossed with the fine English variety, *Victoria (Trolllop's)*, a large continuously-bearing strawberry, which produces fruit as large as the English or American kinds, and continues to bear up to the first frosts. A large variety, said to be continuously-bearing, had been already raised (by Mr. G. G. I. think) but of this the leaves alone were "continuously" produced. That of M. Mabille, which we have ourselves seen and tasted, is quite a different thing. We do not hesitate to strongly recommend it, not only for its large fruit and really continuously-bearing varieties, superior to itself. The general consumption of this excellent fruit is so desirable that we must commend every effort to increase it, and render it accessible to all. In connection with this subject we have just read the following in the *Echo du Parlement Belge*:—"Within the last few days an exhibition of strawberries has been opened at Boskoop (Holland). One lot, containing fourteen strawberries, weighed over a pound." This comes very near the "twelve to the pound" of M. Mabille. We hope that it may become as excellent and productive as the Caprons of the marshes of St. Land, at Angers, which we used to purchase at the rate of twopenny halfpenny the basket of five pounds.—*Ed. André, in L'Illustration Horticole.*

Apples and Pears in Orchard Houses.—What does our correspondent "W." (see p. 188) grow apples for? Does he do so simply for their appearance in the orchard house? or are they cultivated there for what they are worth? If for pleasure only, I have nothing to say to those who choose to spend their money in that way; if for profit, does not "W." very lamely support his advice, to grow them in orchard houses when telling us that such delicious apples as the Newtown Pippin may be bought for half-a-crown the stone of fourteen pounds? In short, I feel certain that if his orchard house apples even exceeded his most sanguine expectations, and he was able to sell them at four times that price, he would be a loser, after deducting interest for outlay, repairs, and deterioration, to say nothing about labour. I am, however, ready to admit that the larger trees which "W." proposes are a step in the right direction. As regards the culture of pears and apples under glass, may I recommend your correspondent who advises our gardeners to grow them in that way to pay a little attention to the stupid and benighted market gardeners and fruit growers who supply our markets. They are not perplexed with a hundred duties, like the gardener in a private place; working on a large scale, and with perhaps not more than half-a-dozen subjects to deal with, they can at once test the merit of a system. Yet, we see no sign of them adopting the wonderful orchard-house plan for the production of our commonest hardy fruits. Nevertheless, gentlemen are sometimes led by such statements as those of "W." to adopt these fanciful systems of culture, which, however successfully carried out, fall short of their sanguine expectations. Then, unless the gardener happens to be a man whose abilities are known to be equal to anything that it is possible to attain, he is at once set down as incompetent. The fact is, it would be absurd to devote any of our precious glass-house space to these fruits while other tenderer ones are badly in want of it. So long as apples are grown to perfection in many parts of this country, and so long as the superb apples of the orchards of the vast American continent can be safely and cheaply brought here, it will never pay anybody to grow these fruits under glass.—T. BAINES, *Southgate.*

Why not cut Grapes when Ripe, and "Bottle" Them?—Having suffered this last damp autumn through, not cutting all our grapes when they were ripe, I intend to show your readers how a good house of muscats was nearly all lost. We have two fine muscat houses standing on a very high hill, two hundred yards away from the main range of houses. On one very wet day the men were sent to give the vines in these two houses a few cans of water, but, instead of giving the quantity ordered, they poured water on the inside border for six hours; and owing to the long level length to which the fine runs, the fire does not draw at times. The consequence was, with two or three wet days in succession, and the fire almost out, nearly 200 bunches of finely-coloured muscats were almost all spoiled. I am glad to say, the border was not watered with my consent; but, nevertheless, the water was applied, and

the house was filled with cold, damp moisture. Now, if I had cut every bunch from the vines the first week in October, with about eight inches of the stem attached to each bunch, carried them into a dry room, had a number of bottles ready filled with clean spring water, and with a little charcoal in each bottle to receive the bunches, I feel certain we should have had fine muscat grapes until March, and thus have saved all the trouble and expense of firing and air giving. Last year we ate the last bunch of Mrs. Pince in fine condition on Good Friday, and the last bunch of Lady Downes the last week in March. If these two kinds of grapes were cut at Christmas, and the stems put in bottles of water, as just described, I have no doubt that a great deal of trouble would be saved, and the vinegars could be filled with plants. The inside border might then receive some water, instead of being kept dry all through the winter, as most of the inside borders are kept until the soil in two or three years time loses all its strength. If, however, such growers as Messrs. Fowler and Meredith would give us their experience as to the best way of keeping late grapes, it would be a boon to many. But, until I hear of a better plan, we shall in future cut all grapes when ripe, put their stems in bottles of water, and place them on a shelf in a dry room.—T. S.

Fruit Trees for Cottagers.—Many who have the means delight to improve the gardens belonging to labourers' cottages. I am about to build several cottages for my workmen, and to give half an acre to each; can you, therefore, kindly tell me where fruit trees, dwarf and suitable for such gardens, can be obtained at a cheap rate? [Are the dwarf trees which I see advertised in pots, such as apples, pears, peaches, plums, &c., suitable to transplant in open gardens for cottagers' use?]—JAS. SHRIK.—[Dwarf apples on the paradise stock, and dwarf trees suited for forming neat pyramids of almost every kind of hardy fruit, may now be had in most nurseries throughout Europe. Those raised in pots are too expensive for any but indoor work.]

Reverting to the Original Form.—Those who believe wheat will turn into "chess" have had much to aid them of late. A wonderful instance of vegetable transmutation is mentioned by a correspondent of the *Iowa Homestead*. A farmer purchased of a tree pedlar fifty different varieties of apples for a large orchard. In a few years these apples resolved themselves into a single kind, neither rare nor of good repute.

THE SIX OF SPADES.

CHAPTER II.

WHEN young Mr. Chiswick, the gardener at the Hall, made his first appearance in our village, he was generally supposed to be an officer of cavalry on leave, or a foreigner of distinction on his travels. Great was the surprise accordingly, when, coming to church the Sunday after his arrival, he took his place with the domestics, and not with the Squire. Nevertheless, though he fell in the social scale, he rose in the estimation of our villagers. Here was a handsome young fellow, with the neatest of moustaches and the trimmest of beards, not come to marry Squire Granville's daughter, and, therefore, no longer a fascinating impossibility to the more humble maidens around. Mademoiselle, Lady Constance's maid, at the Castle, immediately traced in Mr. Chiswick's limacaments a striking resemblance to the old French *noblesse*; the damsel who assisted at Lady Isabel's toilette, was sure that he had been accustomed to the best society; Miss Granville's attendant was forcibly reminded of Lord Byron's "delightful Corsair"; and all our unmarried beauties expressed their true commiseration, "that such a pleasant young man should be buried alive in that lonely cottage, belonging to the gardens at the Hall."

There were dissentient voices, of course. Our young men spoke slightly of "Jews" and "barbers' blocks." Mrs. Verjuice, the housekeeper at the Grange, declared his "manners was 'igh, and his appearance 'airy." And even the mild, kind-hearted Mr. Oldaeres was reported to have murmured something about "a Pomological Puppy," to have spoken disparagingly of Mr. Chiswick's "foliage," to wit, his moustaches and beard, and to have told the Duke's huntsman, that "he would find some excellent covert at the Hall, when he wanted a fox, next season." I think that a little breeze of apprehensive jealousy stirred the tranquil waters of that grand old heart. Mr. Chiswick had won medals at the London shows; there was to be a new orchard house at the Hall (poor Mr. Oldaeres had only four, well-stocked with fruit-bearing trees); and our King of Spades looked sternly (it was but for a moment) from his palace upon the modest vineyard of Naboth.

Now what do you think that the King's daughter, at this crisis of our history, the Princess Mary of Oldaeres, went and did? Exactly so; for I know that you have guessed it; she did, indeed. As you, my subtle reader, have well inferred, she did not wear her second best bonnet, much less did she distort

her very lovely face with unnecessary sniffs and sneers when she met the bearded knight, whom the King her father was disinclined to honour. The knight fell head over beard (his ears were planted out by extensive shrubberies, and so I vary the old expression that they may preserve their position of retirement)—head over beard, in love with the Princess, and “Jill” (if I may apply such a term to royalty)—“Jill came tumbling after.” When Mr. Chiswick had got sixty-eight runs from his own bat in our annual match with the Slawmey Slashers (it is only fair towards our neighbours at Slawmey to remark that their best bowler was unable to attend, in consequence of a very pressing engagement at the treadmill of our county jail), and was carried from the wickets upon the shoulders of his rejoicing and victorious friends, I saw the bright colour rise on Mary’s cheek as vivid as the Poinsettia; and again, when in our contest with the picked eleven from Moughboro’ some clumsy ruffian, shying in widely, hit our pet batsman on the head, and

“round he spun, and down he fell.”

I saw poor Mary—indeed I went to tell her that there was no serious hurt, having an earnest sympathy with lovers—vainly endeavouring to conceal her sore distress, and as white as Azalea candidissima. And so it came to pass, on a moonlit January night, when, in spite of the Under-whip’s protestations, that “he never could see the use of them frosses,” the Castle Lake had been covered with skaters and spectators; it came to pass that Mr. Chiswick, after astonishing every one with his “eagles,” and figures, and “outside edge,” and turning about and wheling about on his skates, as comfortably as the celebrated Mr. Crow without them, walked home with Mary Oldacres. And he told her, as they walked, his Winter’s Tale. He spoke of his loneliness in his cottage-home with so much bitter plaint, that you would imagine the Moated Grange of Mariana, or the Haunted House, so wondrously described by Hood, to have been quite festive residences, halls of dazzling light, and abodes of the fairies, when compared with his Den of Despair. He described in harrowing terms “the fearful sense of desolation which oppressed him, and would, he knew, oppress him that very evening, when, alone and dolorous in his dreary cave”—(Oh fie, Mr. Chiswick, Mr. Chiswick! how can you thus defame your cozy parlour, with its cheerful fire and singing kettle? how can you thus ignore your horticultural books, your cornet-a-piston, upon which I heard you playing but two nights ago, in your divine despair, the melancholy air of “Old Dan Tucker”?)—“where no sound was to be heard save the sorrowful sighing of the wind” (he said nothing about the snoring of his small servant asleep in the contiguous kitchen) “and the dismal drip of the rain” (here Miss Oldacres looked up into the cloudless shining heavens, as if wondering wherever the rain was to come from), “he should sit, like patience on a monument, smiling at grief”—the monument consisting of a very easy chair, and grief being represented by a plump little pipe of Bristol bird’s-eye, and a glass of gin and water, “hot with.” Finally, this unhappy plaintiff, whom you could not have identified with the smiling skater shooting over the lake only half-an-hour ago as though he had backed himself to catch an express train, after glancing briefly at the delightful privileges of self-destruction, the repose to be found in Yellow Fever, and the unspeakable consolation of being killed in battle, in cases of severe disappointment, asked Mary Oldacres to be his wife; and I am quite sure that the bright moon, in all her great experience, never looked upon a happier couple as they came home, hand in hand, and heart in heart, that night, through the silvered grass. Mr. Chiswick returned to his “dreary cave,” and evoked unjust suspicions of his sobriety in the small servant by informing her that “life was ecstasy, and he should raise her wages;” and subsequently proceeded to evoke the sparrows outside, with “Love’s Young Dream” from the cornet.

You ask, perhaps, at this crisis, with the fast Oxonian in the song, “but what will the Old Governor say?” and I must tell you, in answer, that the primary chilliness to which I alluded, soon thawed in the warm bosom of Mr. Oldacres, that he made an acquaintance, and then a friendship with Mr. Chiswick, and that Romeo knew, when he astonished the sparrows, that he had little to fear from Capulet. And this

was so, because the younger man ever tendered to his senior that due respect and deference which is not quite so common in these days as it certainly is just and seemly. Mr. Oldacres had expected to meet a supercilious dandy, who would sneer at his superannuated notions, and would expatiate, in a language half Latin and half science, upon the Metaphysics of Botany, or some pleasant little theme of that sort. He found, on the contrary, a quiet, unassuming, well-informed man, clever, and highly educated in his art, but more anxious to listen than to speak, as one to whom knowledge was teaching her noblest lesson, to be aware how little he knew. “Mr. Oldacres,” he thought, “had not the great advantages which were given to me in those dear old gardens of the Horticultural Society under the wise supervision of ‘the Doctor,’ and yet how much have I to learn from one who has spent a long life at work, at work upon the best material, and with the most costly tools.” And the old man, seeing himself appreciated, was prompt on his part to acknowledge the acquirements of his new neighbour, to exchange information, and to compare old things with new. I met him one morning returning from the Hall gardens, and he informed me that “Chiswick was a regular conjuror.” He had just seen him “tie out” a young Pimelea, recently received from the nurseries, and he had made it look worth a guinea! And the best of it was, he went on to say, “that the fellow had no more pride about him than a Dahlia after a hard frost,” and when he praised his handiwork, he only said, “I wish you saw William May’s.”

And thus there arose between these two men, so dissimilar in aspect yet so congenial in mind, a sincere regard and amity, which deepened into a most true affection, when “the Gardener’s daughter,” quite as loveable as Mr. Tennyson’s, went over from the Castle to the Hall, and precocious Chiswicks, as tame went on, began to drive miniature wheelbarrows between Mr. Oldacre’s legs. For the clergyman who made the true lovers one was a true prophet when, he said, “Thy wife shall be the fruitful vine upon the walls of thine house;” and whoever enters that pleasant home, once called the Den of Despair, and sees the bright young mother among her laughing little ones, beholds the realization of those other gracious words, preceding the words which I have quoted, “O, well is thee, and happy shalt thou be!”

And while the pretty Mrs. Chiswick conducts the nursery department, and every year some “striking novelty” is added to her “hardy annuals,” “quite distinct,” and a “decided acquisition” in the happy mother’s eyes, her husband is making admirable improvements in the spacious gardens of the Hall. His predecessor, old Mr. Woodhead, had been a hard-working man, and a good gardener as far as he went, but he was, metaphorically, a slow horse, more adapted for harness than for hunting, and when he had reached a certain point in horticulture, there he stopped in hopeless immobility, and no spurs could induce him to charge another fence. I remember, year after year, the same plants in the conservatory (ah, those were merry times for the aphis, “days of strength and glory” for the red spider!) the same designs in the flower garden, the same bouquets in the drawing-room, and the same fruits and flowers upon the table. I think I see his Cinerarias now, with their pointed petals (number unknown) widely separated, as though they hated one another. The ladies of the Hall were delighted indeed when such flowers as “Lord Stamford” and the “Scottish Chieftain” (I am speaking of favourites in request some sixteen years ago) displayed these dingy specimens; and yet more gratified were they, when the summer came, and, sitting upon the pretty garden chairs of Mr. Chiswick’s design, they saw the beautiful contrasts of modern taste, Flora’s bright jewels set in gold and silver (“Golden Chain” and “Mangle’s Silver”), and set so skillfully that, while each separate gem shone in its distinct and glowing beauty, the collective whole charmed the eye with a perfect unity. “Scarlet and gold, scarlet and gold, Tom Thumb and Rugosa Calyx,” had been old Mr. Woodhead’s motto; and of those he “bedded out” many thousands, making his garden so gorgeous that strange carriage horses, emerging from the sombre shrubberies through which you approach the house, would actually shy at their sudden splendour; and the vivid brilliancy was so painfully unrelieved and monotonous that it seemed almost to burn one’s eyes.

Mr. Chiswick made a hundred other improvements, of which I have no time to tell. That damp shaded corner, under the trees of the "Long Walk," where nothing seemed to flourish but obnoxious fungi (they may have been delicious esculents according to the discoveries of modern mycology, but they had not an appetizing aspect), became a picturesque fernery; the banks of the lake, which had always looked so drear and reedy, are now planted with rhododendrons, which reflect their glories in the admiring waters when the time of flowering comes, and are always beautiful in their glossy sheen; a few trees were felled, and from all the front rooms you can see through the opening our village church in the distance, most striking upon a summer's eve, when its fine old western window blazes and bickers in the setting sun; here is a statue of "Contemplation" admirably posed, with some dark Yews, high and dense, for a background, and giving you at once the idea of a place "where ever-musing Melancholy dwells;" there, passing through an arched stone doorway, you find yourself suddenly in Switzerland, where you may spend a day in admiring those charming little alpine plants nesting in the crevices and crannies of the rockwork, and may taste the alpine strawberries, if you please, though I warn you that this Arbutus is "Unedo," and that you will not desire to repeat the experiment; and, in brief, you will find, wherever you go, some pleasant proof of a refined taste and an untiring industry.

our ferniest mention just one more instance, perhaps the most likely of, of his improvements—the transformation which he of the d^r in "the stove." It was an awful place, that stove, of your re-sign of King Woodhead; and Mr. Chiswick pretended, in a merry mood, that, on his first visit, "a mealy bug, of about Chitie stature and ferocious dimensions, had lashed out at from a flake a horse." Certainly there was more to interest the being romologist than the florist in this remarkable collection. I suppose that the Orchids must have flowered at night, for I doubt ever saw them emerge by day from their residences of rotten wood and moss, where they seemed to exercise unbound'd hospitality, and to keep open house for the lower orders of vermin. There were creepers which declined to creep; sticks trained to enormous globes, but showing no inclination to start upon their travels round them; and plants, on the other hand, which grew like the fairy's bean-stalk, Allamandas, for instance, stretching their arms all over the place, but of flowers "devil a taste;" there were tall thorny Euphorbias about as full of bloom as a hedgehog; there were Begonias with great cracks in their giant "ears," and places which looked as though bitten out by "elephants;" there were Hoyas and Stephanotis, whose every leaf called out, in dying pain, for "Gishurst;" and all the time these helpless, hopeless invalids were insulted and mocked by dirty little "tallies," who persisted with bitter irony in calling them "Bellas," and "Splendiferissimas," "Magnificas," "Grandiforas," and "Elegantissimas."

When I see the place now, I cannot recall its former appearance. The Orchids bloom; the Allamandas, the Ipomeas, the Dipladenias, the Gloxinias bloom, in all their delicate loveliness; the Hibiscus and Passiflora flower, as they rise in profusion; and the plants of variegated foliage, the Alocasia, the Cissus, the Croton, are models, both in the healthfulness of their growth, and in the symmetrical arrangement thereof. Here let us leave Mr. Chiswick, happily admiring a beautiful Caladium argyrites, and pass on to another member of our brotherhood.

Ah, mine old acquaintance, the terror of my childhood, the enemy of my boyhood, the friend and faithful servant of my manhood, are you the next to sit for your portrait? I must have a new piece of canvas, and grind some fresh paints, for you.

S. R. H.

(To be continued.)

TO THE EDITOR OF "THE GARDEN."—I want to tell you how much obliged I am by your exhumation of "The Six of Spades." I read portions of it when it came out in the old *Florist*, and often have I wondered how and when I might be able to read all the papers entire. I felt a peculiar interest in them, because I have been in the garden-house at Caunton, the place of meeting of the Six of Spades; nay, I have been at one of their meetings, and I can say that the heartiness and good fellowship described by Mr. Reynolds Hole was

not in imagination but in living reality. The description of the garden-house is literal, and the good cheer provided and dispensed so freely by the host was not so in name only, but in solid and enjoyable reality. His old gardener (Mr. Evan Hirst), whom he describes so well under the name of Mr. Evan, was a friend of mine. I showed chrysanthemums against him at the Nottingham exhibition in the same year in which these papers were written, and the silver cup that Mr. Reynolds Hole describes that his chrysanthemum had won was the cup he and I and a few others tried for at that exhibition, but which he most honourably and honestly won from us. All things considered, you may understand my joy to see that you have determined to give us these charming papers again through the medium of THE GARDEN.—N. H. POWELL, Radcliffe-on-Trent, Notts.

THE INDOOR GARDEN.

THE INDOOR GARDEN FOR FEBRUARY.

BY T. BAINES, SOUTHGATE.

Conservatory.—Keep up a succession of blooming plants for this structure, by regularly introducing to the forcing-pit or stove such plants as are required. Nothing is more useful than the better kinds of Ghent Azaleas and hybrid Rhododendrons; but as regards the latter, care should be taken to select the earliest kinds, such as Caucasicum pictum, Cunningham's White, and similar varieties. A few bushy Laurustinus will be found useful. Some also of the greenhouse Azaleas ought now to be brought in, using the smaller sized plants, or such as it is desirable to grow on to a larger size, which, by being started now, will have a much longer season of growth than if allowed to come later. Genistas and Acacias, especially the old A. armata and Drummondii, are most useful flowering plants for spring, for they stand cutting well. For scarlet flowers during winter and early spring, nothing is more useful than the bedding Geranium Vesuvius; it is one of the few that will produce its flowers freely in heat, if the plants have been properly prepared in autumn. Re-arrange the plants in conservatories or other show-houses occasionally; a great deal may be done even with the same materials, to avoid that monotony which exists if plants similar in size and otherways alike are always to be found in the same positions. Place the plants so as to break that regular graduating surface which is so objectionable in stages of the old construction. There is no plant that stands heading down better than the Camellia; where, therefore, the plants are at all leggy, a portion should be headed down each year. The operation should be done at once, and the plants allowed to stand in a cool house for a month afterwards. If deferred until later in the season, or placed at once in heat, they will bleed so as to injure them very much. Herbaceous Calceolarias will require potting on. Sow now a little seed of Primula and Cineraria for autumn and winter blooming.

Stoves.—Most of the plants here that have not already been potted will require a shift at the end of the month. If the different potting materials required for the operation have been got under cover as previously advised, they will now be in good order for use, but on no account employ any of them—peat, loam, rotten dung, or sand—cold from the shed. Let all be placed before using them near the hot pipes, or in some other place where they will get thoroughly warmed through so as to be of the same temperature as that of the house in which the plants to be potted are grown. Let such peat and loam as are used be of the best description, containing plenty of fibre and not too much decomposed; if it has been stacked sufficiently long to allow the vegetable matter which it contains to become dead, that is enough. I would much rather use soil in which the vegetable matter which it contains is not more than half dead than employ it when too far gone. It happens sometimes that the peat and loam procurable in certain neighbourhoods are deficient in fibre, in which case it is advisable to sift a portion of the earthy matter out of them before using them. Large plants of Allamandas, Clerodendrons, Bougainvilles, and Dipladenias, and other occupants of the stove that were dried off in the autumn, so as to lose all or the greater portion of their leaves, should have half the old soil removed and be replaced in the same pots. The plants I have just enumerated, except the Dipladenias, do best in loam well enriched with rotten dung. All the varieties of Dipladenia require good peat and sufficient sand to insure porosity. Ixoras, Combretums, Gardenias, and other evergreen plants of similar character, succeed best in peat, and should not have their roots too much disturbed in potting; on the contrary, simply remove a few inches of the surface soil and replace it with new material, and in the case of young, growing plants it is not advisable to remove any of the soil, but to pot on into larger pots. In all cases let the condition and quantity of roots that a plant has got determine the size of pot

that shall be used; where the roots are healthy and plentiful give a liberal shift; where the reverse is the case it is advisable to return the plant to the same or only a very little larger pot. This holds good in the case of all plants. Crotons, Dracaenas, Palms, and Theophrastas do best in good strong loam, using plenty of drainage, as these are water-loving plants. Marantas, Difenbachias, and the larger growing Anthuriums, succeed best in peat. All plants (orchids excepted), previous to potting, should receive sufficient water to moisten the whole of the ball, so as to obviate the necessity of applying water for a short time after potting; this gives any roots that have been injured time to heal. Continue to introduce into heat such plants as are likely to be required for succession-flowering, being careful not to use more warmth than is necessary, or weak, flimsy flowers will be the result.

Fern House.—The first or second week in this month is a good time to go over ferns, re-potting such as require it and top-dressing others, using good peat with a liberal admixture of coal cinders broken to the size of acorns; these are more effectual in keeping the soil open than potsherds. All tree ferns grow quickest when their stems are syringed once or twice a day during their season of growth, but if they are required for the decoration of halls or for exhibition at times, it is better not to syringe, as the roots that are encouraged by syringing receive a check, in which case they had better not have existed. Large Gleichenias may be divided, but not into small pieces; plants, say in eighteen or twenty inch pots, may be divided into two or four. Of all ferns for mixing with flowers, either in vases or in bouquets, Gleichenia Speluncæ stands pre-eminent. It will last for a week in water. It is not advisable to cut small plants; but, when well managed, all the varieties are quick growers, and when the plants get large they will bear cutting in moderation with impunity. In large ferneries, where most things are planted out, the selection and planting require judgment, in order that suitable varieties may occupy the positions for which they are best adapted, studying well what proportions each individual plant is likely to attain, quite as much as present effect, otherwise, instead of a satisfactory arrangement of these most elegant of vegetable forms, a confused jumble will be the result. Another important consideration is to have the plants free from insects, such as mealy bug or scale, otherwise endless labour will be entailed. Such kinds as Adiantum Farleyense and the Gymnogrammas require more heat during the winter than the majority of the occupants of the fern house, and it is better to remove such kinds for the winter to a little warmer house. The fern house during winter ought not to be kept at more than 50° night temperature, with a rise of 6° during the day. It is a mistake to use too much heat in the fern house, as it makes its inmates so tender that such as are required for cutting flag so as to be almost useless, and if the plants are required for decoration elsewhere they suffer as well as become unsightly. As soon as growth commences supply them liberally with water.

Orchids.—Let sufficient of the best fibrous peat, sphagnum, and clean crocks of different sizes be prepared for the general potting of these plants towards the end of the month. It is bad practice to allow Orchids to remain too long in the same material, for even if it appears sweet on the surface, it may be sour underneath; in which case the roots will rot as soon as they enter it. At the same time Orchids, more than most plants, dislike moving, on account of the impossibility of doing it without breaking many of their roots; consequently the greatest care ought to be exercised to reduce the breakage as much as possible. Do not apply much water for a week or two after potting; but increase the temperature 6° or 8°, which will help root-action. Use also more atmospheric moisture. For Vandæs, Saccalabiums, Acridæs, Phalaenopsis, and Angraecums, use sphagnum only, with a liberal admixture of crocks. Cattleyas, Lælias, Oncidiums, Epidendrums, and Odontoglosses, thrive best in a mixture of peat and sphagnum in equal parts, using for these sufficient, say one-sixth, potsherds, broken moderately small. In potting, employ sufficient sticks to secure every plant firmly in its place; for if left loosely in the pots the young roots emitted suffer every time the plants are stirred in cleaning or on other occasions, which may necessitate their being moved. Finish every plant off by using about half an inch of the surface material considerably wetter than the rest; press this down evenly with the hand, and it will form a sort of crust to the whole which will not be so easily removed with the syringe, and will in some measure prevent insects, such as beetles or woodlice, from harbouring in the pots.

Hard-wooded Plants.—Bring all tying and training to a close as soon as possible, and prepare for potting all plants that require a shift towards the end of the month. Commence first with hard-wooded Heaths; half specimens and full-grow plants that require more root-room ought to be moved into pots four inches larger than those they at present occupy, for it is not desirable to re-pot these

plants oftener than can be helped. See that the ball in all cases is sufficiently moistened before potting, so that watering may be avoided as long as possible after re-potting. All newly-potted plants should, therefore, be set at one end of the house, and do not admit more air at that end than can be avoided for three weeks or a month, keeping, at the same time, the stags damped with the syringe. Where there is not the convenience of separate houses for Heaths and for other kinds of hard-wooded plants, but where all have to be grown together, the Heaths ought as far as possible to be kept at one end; at which, except after recent potting, admit more air. After the potting of the Heaths is finished, commence with the other hard-wooded stock, using peat a little more fibrous, or what is known amongst plant-growers as softer, than that which is used for the Heaths; operating, in other respects, as recommended for the Heaths. Any additions that are intended to be made to the young stock of hard-wooded plants ought to be made forthwith, and those that require it potted on, giving to such two or three inch larger pots, according to the condition of the roots of each individual plant. All the plants, young and old, ought to have the potting completed as expeditiously as possible after it is once commenced; as then the whole can have what extra attention they require.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Early Flowers.—It may interest some to learn that I have had Tritelia uniflora in full bloom in my conservatory since the middle of December. It is extremely delicate and pretty, and deserves better known than it is. It has been figured by the Joseph Paxton, in his *Botanical Magazine*, vol. xi., under the name of Leucocoryne aliae, but I consider simply a pale-blue form of the hardy bulb just named; however, altogether a slighter and more delicate habit than the common form of Tritelia, and comes into bloom a month earlier than it, as pots of the latter which have been undisturbed since last season's flowering are now just coming flower. Another most beautiful early blooming bulb for greenhouses, but which is likewise, I believe, perfectly hardy, is lovely purple Iris, with a bright golden lip, known to horticulturists as *I. reticulata*.—W. E. G., Belgrave, Queenstown, Cork.

Solomon's Seal for Forcing.—This is nearly related to the lime of the valley, and is also a native of Britain. It used to be common in old-fashioned gardens in shrubbery and herbaceous beds; but I am afraid the present bedding system has reduced the stock of this as well as of many other useful old plants. Whoever has plenty of it has a grand plan for forcing in masses for the conservatory. It does best in not less than ten or twelve inch pots. It grows about two feet high, and as it has large fleshy roots, care must be taken not to break or bruise them in potting.—E. HOBDAY, Ramsey Abbey.

Plants on Staircases.—In the subdued light of ordinary staircases it is only plants of bold and massive foliage that produce a suitable effect. Plants in such situations are generally, on entering the hall, seen with the light behind them streaming down from the window on the first landing; in which case, all the foliage, as seen from the hall, appears dark, and the form of the foliage, if of a bold character, defines very strikingly against the light. I have seen very fine artistic effects produced by fine plants judiciously placed about staircases and landings, where there is room, especially if the space admits of the distribution of the large plants of American aloës being so distributed during the winter months, when they are taken in for protection, after having done duty during the summer months about the lawns and terraces. The stiff and finely formed leaves of plants of this, and some other classes which might be named, harmonise well with the architectural features, which in ordinary houses are generally somewhat more developed in the hall and staircase than in the other parts.—H. N. H.

Rose Rendatier Pelargonium.—It may not be generally known what a useful plant this is for winter flowering; its bright pink flowers are brighter now and of a better shape than they are in summer, and they are also produced very abundantly. I have a house half full of it, that has been a mass of flowers for the last three months. The cuttings were struck late in spring, and grown in the open air in six and eight inch pots; not plunged, but placed on bricks, and in September were removed to a light, airy house, where the temperature is not allowed to fall below 40°. The plants are now many of them perfect little specimens, fit for a dinner-table, with five or six fully developed trusses on each. I have given many other kinds a trial for winter flowering, but never found another so good as Rose Rendatier. This I have grown and watched five or six winters, and it has never failed.—W. M. Taylor.

Lime a Fœ to the Camellia.—One fact connected with the cultivation of the camellia must be omitted, and it is this: it will not grow in soil from the limestone formation; like the rhododendron and other American plants, it seems to abhor lime. In tough fibrous loam from the sandstone formation, taking the lime out of the soil, it will grow well; but in chalky soil, the plant will grow like a willow; and the same may be said of it in such upland areas, poor as it is—it may be procured upon most parts of Sherwood Forest. This laid up for a few months to rot, and then broken up to the size of pigeons' eggs, and the fine soil taken away, is as good a soil as need be used for the plant.—Neots.

Dielytra spectabilis.—This beautiful hardy plant, introduced by Mr. Fortune some twenty-five years ago, is not only one of the most brilliant plants for the herbaceous or mixed border, but it is a grand subject for forcing for conservatory decoration. All plants that are forced early are better for being established in pots some time before they are subjected to heat; therefore, if not potted till late in the autumn, do not push them on too eagerly the first season, and after they have done flowering place them in a cold pit to finish and mature their growth. The following winter they may be had in bloom easily by Christmas. After two or three years' forcing, if any of the plants look weak or spindly, divide the roots and plant them out in the reserve border to increase stock, and to gain strength for future use. It is a good plan to divide and plant out half the stock every year, reserving the strongest for the earliest bloom the following season, and potting a like number from the reserve bed to force in succession. When blooming is over let them have the same attention with watering, &c., till the growth is matured; then plunge them in a coal-ash bed for the summer; neglect in this particular may injure their blooming capabilities for the following winter.—E. HOBDAY, *Ramsey Abbey*.

Climbers for a Cool Fernery.—Will you kindly give me the names of free-growing evergreen climbers, to plant in a fernery not artificially heated?—C. P.—[If the fernery be not much shaded, and there is no reason why it should be, any admired kind of greenhouse climber would do in it, from the splendid *Tacsonia Van Volxemi* to the *Lapagerias*. The hardest of the passion flowers would do well; so would fuchsias trained against the roof, and allowed to hang down. Indeed, a good plan would be to use no shading material except that afforded by the climbers, which might be allowed to cover the whole of the roof. The climbing ferns *Lycopodiums* should not be forgotten, nor the creeping fig, so useful in the fernery. A very small Japanese form of the creeping fig—a gem-like miniature of the common *Ficus repens*—will prove a great addition to our ferneries. We saw it in Mr. Hogg's garden at New York last year.]

Lily of the Valley.—Having read the article on the treatment of lily of the valley in pots, at page 168 of THE GARDEN, I beg to ask any of your readers whether they experience any difficulty with plants treated as recommended there coming into bloom in autumn? My reason for presuming to inquire is because I have seen plants that had been forced about Christmas, and treated in a similar manner, throw up flower spikes from a few of the plumpest crowns in each pot during autumn, without being removed from their summer quarters. Now, without saying whether the flowers so thrown up are useful or not, I may just remark, what is no doubt well known, that it renders them more or less unsuitable for winter flowering.—AN INQUIRER.

Plants for a Greenhouse with a North Aspect.—I am very desirous to grow a few plants to make a small greenhouse gay during the year. The drawback is the aspect—it faces the north. Would you kindly favour me with a list of plants which will thrive in the shade in a greenhouse?—F. S.—[Aspect alone should not defeat you, if the light is not much shut out from other causes. Perhaps some of our correspondents will kindly help you.]

THE PROPAGATOR.

THE ART OF GRAFTING.

(Continued from p. 213.)

GRAFTING under glass requires certain accessories, such as pots, composts, mats, screens, canvas, coverings, &c., although the stocks grafted are intended for future culture in the open air. When the young grafts begin to vegetate, stakes, osiers, and rushes, are indispensable auxiliaries. The stakes are made of small branches or twigs of resinous trees, or of willow, poplar, chestnut, &c., cut in different lengths. These are more manageable than stakes made of split wood. They will last for a long time if plunged, when fresh cut and prepared, into a bath of dissolved sulphate of copper (bluestone), made in the proportion of about one pound of the sulphate to four gallons of water. Saplings more or less branched will answer for staking young grafts on strong, well-grown stocks. These should be treated with sulphate of copper like the others. The solution may also be applied with advantage to mats, canvas, hot-bed frames, &c., as anything so treated will be secured from the attacks of insects, snails, or other vermin.

OSIERS (*Salix purpurea* or *S. vitellina*) are cut in winter from pollards. They are used, either fresh or dried, for fastening stocks or branches to the stakes. They are sorted in sizes, tied in bundles, and put in a shady, dry place. They should be soaked in water for at least twenty-four hours before using.

RUSHES (*Juncus diffusus* and *J. glomeratus*) are used for tying up young herbaceous scions to the stakes. When the scion becomes woody, the rushes will not be sufficiently strong, and must be replaced by osier twigs, strips of lime bark or willow, bast mat, or the leaves of the reed mace and bur

reed. Rushes are gathered in summer, dried moderately, and laid by in a loft. They require to be steeped in water for only a few hours before using.

STOCKS AND SCIONS. RAISING THE STOCK.

FIRST STAGE.—The plants intended for stocks are obtained either from seed, layering, or grafting. A sucker does not answer so well, as the operation of grafting and its consequences have a tendency to excite it to produce suckers.

SOWING.—Seeds should be sown as soon as they are ripe:—1st, from April to June; 2nd, from August to October. If it is not convenient to sow them immediately, they should be placed in a shallow vessel, in alternate layers of seed and sandy soil, and laid by in a cellar. When they begin to germinate, they may be sown in the open air. The soil of the seed-bed should be well pulverised and carefully cleaned. The seed may be sown either broadcast or in rows, or in holes. When it is small in size, or near germinating, or when the season and the soil are cold, it should be but slightly covered. If sown too thickly, the seedlings will be puny; if too thinly, they will remain short and sprawling. The vigour of the plant and its ultimate destination, should be taken into account. If the sowing has been too thick, it should be judiciously thinned out in summer. Earthing up, watering, weeding, destroying insects, and keeping off birds, are matters requiring some attention.

LAYERING.—This is performed in spring, summer, or autumn, with woody or herbaceous branches not separated from the parent stem, around which a small trench is dug at a short distance. Into this the strong and healthy branches are pegged down, then bent abruptly, and the end turned up vertically, and cut off, so as to leave a couple of eyes above ground. The trench is then filled up with good soil. In *multiple layering*, a branch is laid down from the parent stem horizontally in a trench. This branch should form a number of young herbaceous branchlets about three or four inches long. Each of these will take root, and in autumn may be cut away as a separate plant. Kinds that are slow in sending out roots should have an incision made either lengthways or across, immediately under an eye on the part that is put under the soil. Tender kinds and evergreens should be layered in pots. In all modes of layering, the layer should be separated from the parent plant as soon as it is well rooted. It is then taken up, and planted permanently in the nursery.

HILLOCK LAYERING is used for the quince, the Paradise and Doucain apples, the plum, the fig, the hazel, &c. The stock is cut down level with the ground; in summer, a small mound is raised about it, and the ends of the young shoots are pinched, which excites them to throw out a number of rootlets. In autumn the mound is cleared away, and the young stems which have taken root are separated from the stump, and planted out. If a shoot should be badly rooted, it should be earthed up again until the following year. Stumps may be thus layered every year, or every second year.

CUTTINGS.—Pieces of branches or of roots, when placed in the soil, take root, grow, and form a new plant. These pieces, if of branches, should be from ten to sixteen inches long, and have one or more eyes. If of roots, they may be from two inches to six inches in length. Cuttings of branches are planted in spring or in autumn, and at this last season should be planted at once, as soon as they are prepared. If planted in spring, they should be prepared during the previous winter, when they should be cut, and buried vertically, upside down, in a trench deep enough to cover them completely. When spring arrives, they are planted out in their natural position, and so as to have one or two eyes above ground. Kinds that are inclined to throw out underground shoots, like the Manetti stock, should have all the eyes removed from the part of the cuttings which is buried. A cutting with two eyes should be completely buried in the earth in a vertical position. This is a good plan for subjects of a tender kind, which do not bear frost well, as the vine and the fig. Instead of a shoot, a thick branch or a stem may, in some cases, be planted as cuttings, and will take root. The poplar and willow succeed in this way. Root cuttings consist of pieces of

root from two inches to six inches long. They are planted in trenches in a shady place, in such a way that a very small portion of each cutting is exposed to the air. Short cuttings which have not more than a single bud are planted under glass in a cool place. Cuttings of evergreens succeed best in this way. Transplanting consists in taking up young plants, and replanting them in another place for a time, with the view of developing the fibrous roots and strengthening the neck of the plant. It is chiefly practised with plants raised from seed, which are transplanted after the first year's growth. Seedlings of resinous trees and evergreen shrubs should be transplanted between the middle of August and the end of September, or between March and May. Seedlings of deciduous trees should not be removed until the sap has gone to rest, and in their case only can the stems and roots be cut too long. Transplanting is done with a dibble, in rows of about eight inches apart, with a distance of four inches at least between the plants. After a couple of years, the plant will be sufficiently grown to be removed to the nursery or to a permanent position. By planting it at once where it is intended to remain, we avoid both the cost and labour of a future transplanting and the delay, as well as the chance of failure. Careful nursery treatment is almost indispensable for very young subjects, which require continual attention in culture and pruning.

THE NURSERY.—This should be in a favourable position, well aired, well drained, and having good, easily worked soil. Porous soils, which are liable to be always too dry, should be avoided if possible, as also should those that are too compact, as they retain the water on the surface. As regards the improvement of the soil in a nursery, a mixture of vegetable mould is preferable to manure off the dung heap. A tree raised in soil richly manured is better than one grown in bad soil, but inferior to one grown in good natural soil, composed of various elements. The ground is broken up before winter, and the soil and compost mixed together in the trench, and not deposited in layers. Stones, roots, and weeds are removed. When the season for planting arrives, all that has to be done is to level down the soil, giving it a second and final turning. Although we are not partial to the use of dung-heap manure in nurseries, nevertheless, soils of inferior quality must be improved by the addition of slowly-decomposing materials, which will impart to them the elements in which they are deficient, and secure a vigorous growth to the plants. Such are road scrapings, deposits of streams, stable refuse, old mortar or plaster, garden rubbish, old bones and horns, cinders, parings off meadows, sand, &c., all which are to be mixed and spread long before the time of planting.—*Charles Baltet.*

(To be continued.)

AURICULAS FROM SEED.

ONE frequently hears of want of success in raising Auriculas from seed, the fault, as a matter of course, being usually laid to the seed. It is, perhaps, not generally known, that more than ordinary care is necessary to insure success; and this being the case, a few practical hints may be useful to those who take an interest in raising seedlings. As already stated, Auricula seed is a very precarious crop to raise, and much depends on the time of sowing and the treatment given. About the middle of January is the best time for sowing. The seed should be sown in well-drained pans, using rather a light soil, making the surface quite smooth, and distributing the seed very regularly; then pass a little of the soil through a very fine sieve, but only just sufficient to cover the seed. The pans should be placed on a very gentle bottom-heat, and the soil should be kept moderately moist, taking care never to allow it to get either too wet or too dry. In about four or five weeks most of the young plants will have made their appearance. The pans should then be removed, and the young plants hardened off by degrees, very gradually, but still keeping them in rather a warm situation till the end of March. It will then be necessary to remove them into a cold frame. Whenever the weather is favourable, plenty of air should be given, and they must be kept shaded from the sun. As soon as the plants are large enough, which will be about the end of April, the largest of them should be taken and pricked out into other pans, at about two inches apart. During the summer months they should be placed in some shady situation, and kept well watered, so as to maintain them in a growing state. By the end of August

the plants will have made great progress, and many of them, especially of the alpine varieties, will again require to be removed; these should now be potted singly into middle sixty-sized pots, and most of the stronger ones will flower the following spring, a result which plainly shows the great advantage to be derived from this mode of raising the seed, which forces every live grain into vegetation in a few weeks, whereas by the method generally adopted, without the aid of bottom-heat, a great portion of the seed does not even vegetate at all.—*J. Ball, Slough, in "Florist and Pomologist."*

PUBLIC GARDENS.

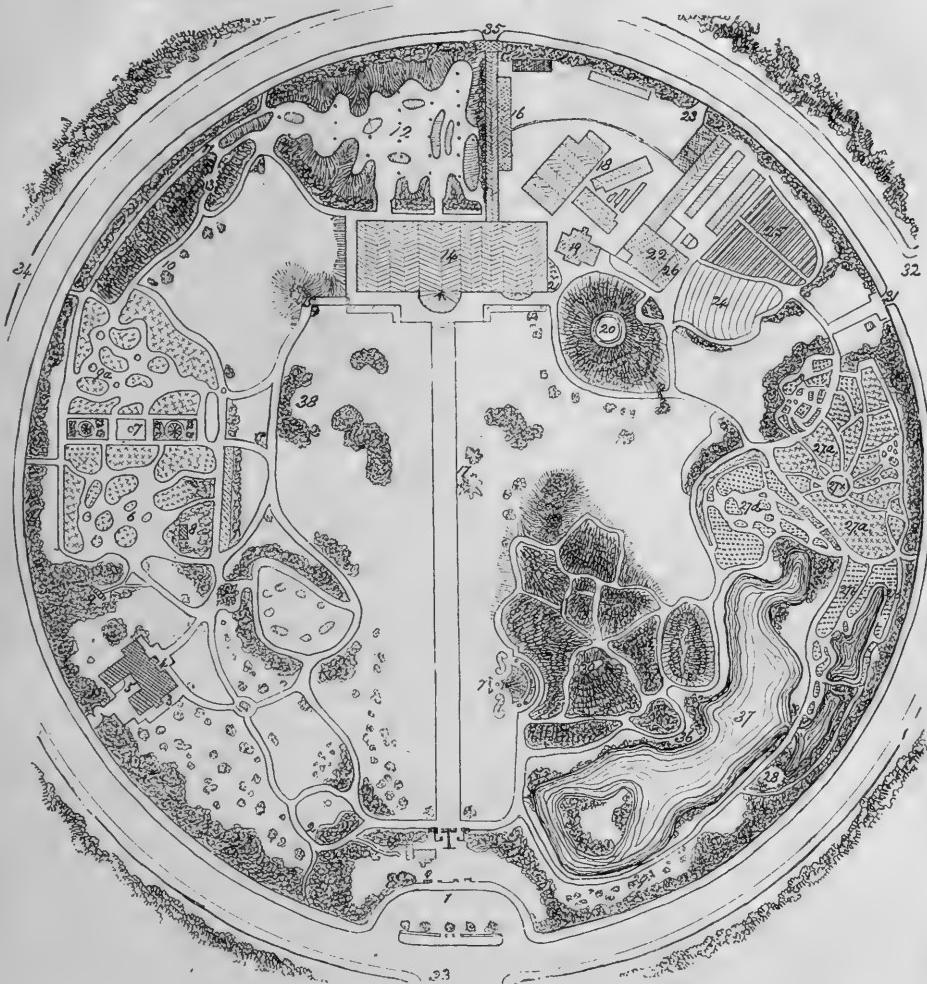

THE BOTANIC GARDENS IN THE REGENT'S PARK.

Few public gardens were ever made on less favourable ground than that of the eighteen acres, the site of the Botanic Gardens in the Regent's Park; and no public garden of the same size has, notwithstanding very obvious defects, been more admired for the excellence of its design. If we cannot include it in the series of articles on the "Great Gardens of Europe," commenced in our last number, we should find it difficult to name one so efficient in preserving the taste for the true art of garden design among us. We have often before spoken of the deceiving nature of plans; but we never felt it more than on looking at this. The most charming feature of the place is its full, easy breadth, notwithstanding the numerous divisions into which, for various purposes, it is cut up; yet, no sufficient idea of this is to be got from the plan. There is another feature in which this garden excels: one, however, of no importance to any but public gardens—we mean its fitness for flower shows and the reception of crowds. As many as 17,000 persons have endeavoured to find room on its pleasant little lawn; and even now, notwithstanding the many counter attractions at Kensington, the Crystal Palace, and elsewhere, it is universally admitted that, for arrangement and for securing the enjoyment of both visitors and exhibitors, no place as yet equals "The Park." It will be the Society's own fault if it loses this pre-eminence. Other gardens laid out with the same aim are models of what to avoid.

The central part of the Botanic is a graceful, free, and natural looking scene, the boundary of which is more like that of a sweet little vale than of what was once a flat circle a little larger than the round pond in Kensington Gardens, and now inclosed by a ring fence and wide road. This and other parts of these gardens help to teach what would appear to be known to but few—probably because a contrary doctrine is practically illustrated by numbers of landscape gardeners—that simplicity of treatment, ease of gradation, and a quiet green foreground, are the soul of an art on which the beauty of the country seats of England so much depends. Such sweeps of ground require only the details of the picture to be properly worked in, the planting to be as free and varied as the scene, to be delightful to everyone who seeks repose or amusement in a garden.

The broad walk down the centre of the garden, and which might be avoided in a private place, rather cuts up the scene; if the whole surface were green, we know no spot in a public garden which would so well illustrate the wisdom of preserving near the house, or chief point of view, an open verdant foreground, and working in the more ornamental details some little distance off, instead of crowding beds and colours all under the windows.

If we next turn to the east side of the gardens, where the artificial water is, equally agreeable glimpses are obtained. The water itself is well managed. The surrounding slopes and banks do not seem to be hybrids between railway banks and ditches, as is very often the case, but fall and dip into the water as they usually do in nature. The well-planted mound, which presents such an agreeable appearance from any part of the garden, but particularly from the water side, has been formed out of the soil dug from the lake, and is a good example of the best course to pursue in the not uncommon case of trying to obtain diversity of surface by using the soil from excavations. Much improvement might be made in the details of the planting, but as a whole the effect is excellent, except when the eye takes in the botanical department.

This, as usual with botanical departments, is not lovely, and there is a considerable portion of ground devoted to it. Such arrangements are usually supported by the State or by universities; in this case considerable expense and precious space are devoted to it by a society. There is probably no garden in existence which supplies so many specimens for lecture purposes. The greater number of botanical lecturers in London sweep down upon it for specimens. From not one of the institutions to which these belong does the Society derive a farthing of support; yet such an institution as Trinity College, Dublin, maintains at very considerable expense a botanic garden to do that for itself which the gardens in the Regent's Park do for the lecturers and students of a number of different bodies. The Society, though nominally botanical, exists solely from its horticultural attractions; and, while it is well to do as much as possible for science, the wisdom of keeping such a large area of the gardens covered with uninviting formal arrangements may well be doubted. The specimens for lectures could be grown anywhere; and considering the large space of ground at Kew, and the fact that that great institution is supported by the State, it surely is the place to furnish the many thousand examples required for such purposes in London, and not the very small gardens of a society the finances of which are far from being in a flourishing condition. It would, without doing away with the hardy plants, be very easy to improve this part of the gardens by laying it down in turf, and in a comparatively small group of beds, preserving the finest and most characteristic only of the herbaceous plants.

The conservatory here is a type of what a conservatory in a public garden should be—curvilinear, with abundant light on all sides, and permanently and well constructed. It is on the whole much better for growing and showing plants than any large conservatory erected near or in London of late years. The plan of growing nearly all the important plants for this and like structures in pots and large tubs is a very expensive and mistaken one. The best plan is that seen occasionally on the Continent—that is, of throwing the whole surface into a miniature garden of the picturesque style. This can be done with perfect success by concealing pillars, roof, and sides with suitable climbers, and by planting out only things of graceful habit, like Palms and Dracanas. The planting-out system for the conservatory has in this country generally fallen into discredit, because Acacias and rapid-growing New Holland plants were the subjects usually tried. These soon ran up to the top of the house, sometimes lifted out the panes of glass, became very scrubby underneath, and even less graceful than the exhibition of small plants in pots which have supplanted them. If the planting-out system were well carried out here, and as far as possible in the addition that is now being made, it would prove a very beautiful winter garden. At present it, like nearly all the other great structures in the country, shows that we have not yet reached the stage in which we see the necessity of studying general effect as well as securing good plants. In connection with this subject we may refer to the remarks of Mr. Baines and M. André, and we hope soon to publish a view showing the effects of a fine house in this style.

As to the other houses here, little can be said in their favour. They are entirely unworthy of a society which should, if anything, set a good example in plant cultivation and arrangement. In London some of our most important branches of gardening are pursued under such difficulties, that it is far wiser to give them up as hopeless. But there is one branch that can be done as well in London as anywhere else—the culture of hot-house plants of every type. Our best collections of these plants are in London. This is the type of vegetation which the Society should take pains to develop. A dozen first-class roomy and well filled houses would do much to increase the popularity of the gardens. It is the more to be regretted that this branch is not attended to, when it is considered that the great nurseries of London are always willing to present public gardens with their new plants, so that there would be no cost for these.

Building a number of roomy houses is, however, a mode of improvement depending entirely on monetary, not artistic, considerations, and therefore it is not fair to blame the Society for this want. But as much improvement is sometimes effected

by the removal of puerilities, eyesores, and absurdities, as by the creation of costly works. Examples of this truth could be pointed out in several of our public gardens. Here, for example, the small Italian garden, marked 7 in the plan, lying between the admirably designed show tent and American garden the "rockwork" in the British garden, and a peculiar variety of succulent house in the medical garden, are among the flaws which it would be wise to put out of sight. It is almost needless to add what everybody knows that the design of the gardens is the work of Mr. Robert Marnock. He also designed the beautifully-arranged show tent which has enabled us all to see and enjoy the delightful assemblage called a "flower show" to the best advantage. The first of its kind, the influence of this admirable tent-garden is now everywhere extending, and no doubt all our great shows will one day be arranged on the same principle. There can be no question that it would be very difficult to make more of, or to vary more, such a very small space of ground as the site of the Botanic Gardens in the Regent's Park.

The Society has recently effected a very desirable improvement in making a new covered entrance to the winter garden (see 35 in plan); we trust that it may be enabled to effect every other change necessary for the continued well-being of the gardens, and that it may long remain the most charming and popular oasis in our great desert of brick.

A GOSSIP ABOUT GARDENING.*

BY ALFRED SMEE, F.R.S.

ABOUT two thousand years ago, the great poet Horace said—that the height of his ambition was to have a garden with a crystal stream running through it, and also a small wood. That also is my case; and my wish, as I suppose his was, has been gratified. Every plant, as most people know, requires light and heat, more or less; and unless it has these it will not grow. It would be in vain to try to grow the sugar-cane in this climate; it would be equally vain to try to grow the geranium in Jamaica. The sugar-cane would not have enough heat here, and the geranium would have too much in Jamaica, so that in either case the plant would perish. The right temperature under which plants will grow must therefore be determined. When I was at Florence, I was told Alpine plants would not grow there, the climate was too hot. Heat and light must not only be applied to every plant, but the plant must rest, and then grow, and then rest again. Rest is as necessary to a plant as it is to man, and many of our plants are not able to be successfully grown because we are not able to give them their precise intervals of rest and growth as in their native homes. Alpine plants in summer are exposed to the full heat of the sun, and in winter they are kept warm by a thick covering of snow. But besides light and heat, there must be at certain times moisture in the air; and unless you are acquainted with the proper time to apply moisture and to withhold it, your indoor garden will be a failure. In the case of the vine, for example, when the leaves are expanding a damp atmosphere is necessary; as its fruit approaches maturity, the atmosphere is gradually dried; and when perfection is attained, we give all the air and light we can, and a much drier atmosphere than before.

Electricity was once thought to exercise considerable influence on vegetation, and experiments have been instituted to ascertain, if possible, its effects on growing crops. We see what it will do in the violent discharge which takes place in a thunderstorm; if a tree is struck, the lightning goes down it just under the bark, and then jumps to the ground where it is wet or damp so that the bark of the tree is peeled off; and this is one of the common effects of an electric discharge on a growing tree. I have the figure of one which was struck in the grounds of a friend of mine. It stood in a field where some hurdles were placed, and the electric discharge could be traced from the tree to a point where these hurdles entered the ground. This may be taken as the effect of lightning upon a tree. Those stories which we hear of trees dying because struck by lightning are merely fables; and as far as I have seen, in many instances, the effect which is produced is that the bark is thrown off and torn and loosened all round the tree. With regard to the immediate effects produced by electricity on the growth of plants, nothing is known, and in my opinion it has no important effect on vegetation at all.

We know how to grow our plants; but how are we to obtain them? In the first place, from seeds. But what do we thus obtain? A plant of a like species to that from which the seed came. Of a

* Abstract of a Lecture delivered impromptu at the London Institution.

like species, but likely to vary somewhat. There are certain limits to variation, but those limits are marked. Take the wild crab, which is so acrid that you cannot eat it, compare that with the ribston pippin. There is a wide difference between them, but within the limit of variation. Take a wild pear, compare that with the delicious pear of the present day, and the variation is enormous, yet it is within the limit of variation, and horticulturists have never found that one species transforms itself into another. But how shall we propagate such improved varieties as turn up by accident or by means of high cultivation? In the first place, it may be done by layering, by which we get a part of the original plant with roots of its own, or by grafting, in which, to be successful, you must bring the new wood of the one against the new wood of the other. By this process we multiply any trees that we like upon another stock.

Again, the same individual may be propagated by cuttings, by division of bulbs, or by that of roots. In short, the point is this: When we want to preserve any particular variety, we must not resort to seed, which may give us a plant different from the parent. Now, having considered the chief points upon which horticultural operations are based, I should like, in imagination, to take you round my garden; and first, as to vegetables. You know it has been said that more people have perished from want of vegetable food than have ever perished in battle. Therefore, what vegetables should we grow? To my mind, the king of vegetables is the watercress. To have it at its best, it must be grown in a pure stream, which ought to come from the depths of the earth at the temperature of 52°, and then ought to run over a clean pebbly bed. To start, you take a handful of watercresses and put a stone upon them, then another, and so on, until you have covered the space on which you want them to grow; and then, if you pick them fresh from the brook, they are one of the most wholesome vegetables which the country can afford. But you often see them grown upon the verge of sewage beds; and then consequences may arise from eating them which are too serious to contemplate. You have heard of the terrors of the tape-worm; you know that it may consist of two or three hundred joints, and that each of these may contain about thirty thousand ova. If you consider that these are common in the sewage beds, and that they are so distributed to the watercress plant, and if you consider that they are thus taken into the animal-economy, you may judge the danger there is in using watercresses, and the necessity for preventing their sale under such circumstances. When they are sold in the neighbourhoods of large towns, the danger is much greater than those who eat them are aware of. We cannot all, perhaps, get perfectly pure and fresh watercresses, but I can. My crystal brook comes to my aid. However, mustard is always at hand. In the shops we buy what is called mustard; but we get rape. These are much alike; but there is a difference in their quality. I will not, however, detain you with salad plants; but I wish to say a word about absinthe, which is a dangerous plant. Absinthe is now drunk enormously in Paris, and I have consulted medical practitioners in France, who say that many brain diseases and epileptic fits are produced by taking this pernicious herb. Therefore, if you have it, have it merely to show persons, that they may not introduce it into this country.

From vegetables let us pass to fruit-trees. I have already told you that apples are mere varieties of the wild crab. But these varieties are very numerous; I have myself more than three hundred kinds. Now, with good management, we ought to have an apple for every day in the year. You begin with a little apple that ripens in July. You go on step by step until you have apples ripening at Christmas. You go on again until March, and then you still have apples—for there are some which do not become ripe until March—and we finish off with the French crab in June, which is not only in perfection then, but will last over a second year; and so, by a little careful adjustment we may have not only culinary, but also eating apples all the year round. About from thirty to forty kinds are amply sufficient for this purpose. Then we come to the pear; but pears are either very fine or very bad, and we must make a much more careful selection. If we begin by the end of July with a small early pear, and go on from one to another, we can have fruit well into the winter. "He who grows pears grows for his heirs," is an old saying. Virgil says, "Plant pears and thy posterity shall gather the fruit." But we know now how to get them much sooner. We cut off the shoot of a pear, and "plant" it upon a quince. By grafting in this way we render the pear tree fertile, and then in a year or two we get fruit which we might have had to wait twenty years for if the tree had been grown in the ordinary way. It is to be observed that the quince stock should be cut off close to the ground, not under the ground, or else the pear will throw out roots, and you will be no better off than if you had planted the pear tree itself. Having planted our pear trees, we must train them in a particular way. We therefore cut the branches into the form of a pyramid, as near
